Phase 1 study of META 10-19, an IL-10-expressing, anti-CD19 CAR T cell product in patients with high-risk DLBCL. First Author: Qianwen Xu, State Key Laboratory of Immune Response and Immunotherapy, University of Science and Technology of China, Hefei, Anhui, China

Background: Chimeric antigen receptor (CAR) T-cell therapy has revolutionized the treatment of B cell lymphoma. However, limited duration of remission remains a significant challenge. We designed a metabolically armored anti-CD19 CAR T-cell product (META 10-19) that autocrine interleukin (IL)-10 to enhance antitumor activity, and assess the therapeutic potential in patients with relapsed/refractory diffuse large B-cell lymphoma (DLBCL). **Methods:** This phase 1 study is designed to evaluate the safety and preliminary efficacy of META 10-19 in relapsed/refractory DLBCL patients aged 3–70 years old. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded by ASTCT criteria, and other adverse events (AEs) were evaluated according to CTCAE 5.0. Tumor response was assessed by investigators using Lugano 2014 criteria and IPCG criteria. **Results:** From December 2022 to December 2024, 14 patients with a median age of 54.5 years have been enrolled and received META 10-19 infusion at doses ranging from (0.002–0.1) $\times 10^6$ cells/kg, following a standard lymphodepletion regimen (30 mg/m^2/day Flu $\times$3 days, 300 mg/m^2/day Cy $\times$3 days). All patients had relapsed/refractory disease, with high-risk features including primary refractory (n = 9), nodal and extranodal involvement (n = 6), CNS lymphoma (n = 5), and bulky disease (n = 2). The most frequent Grade 3–4 AEs comprised neutropenia (100%, 14/14), thrombocytopenia (85.7%, 12/14), and anemia (71.4%, 10/14). CRS was predominantly manifesting as low-grade events (Grade 1–2, n = 13; Grade 3, n = 1). ICANS developed in 2 patients (14.3%) with primary CNS disease, manifesting as transient seizures and classified as Grade 3. At 3 months post-infusion, the overall response rate was 100%, including 13 patients (92.9%) achieved complete response (CR), and 1 patient achieved partial response. As of December 1, 2025, with a median follow-up of 23.3 months (range, 5.6–33.4), 9 patients maintained CR for over 1 year, 4 for over 2 years, and the earliest infused patient remains in remission at 33.4 months. The median progression-free survival (PFS) and overall survival (OS) have not yet been reached, while the 12-month PFS rate and 12-month OS rate were 71.4% and 92.9% , respectively. **Conclusions:** This first-in-human trial of META 10-19, an IL-10 expressing, anti-CD19 CAR T-cell product, for the treatment of relapsed/refractory DLBCL has exhibited manageable safety profile and durable efficacy at ultra-low doses in patients with high-risk features. Studies evaluating larger cohorts and longer follow-up are ongoing. Clinical trial information: NCT05715606. Erythrocyte–anti–PD-1 conjugates in patients with advanced solid tumors resistant to anti–PD-1/PD-L1 therapy: Long-term follow-up of a phase I trial. First Author: Xiaoqian Nie, Westlake University, Hangzhou, Zhejiang, China

Background: Despite the clinical success of immune checkpoint blockade, most patients with advanced solid tumors fail to achieve durable benefit due to limited efficacy and/or immune-related toxicities. αPD-1-Ery is an erythrocyte–antibody conjugate that covalently links an anti–PD-1 antibody to erythrocyte membranes. Unlike conventional antibodies, αPD-1-Ery preferentially accumulates in the spleen, where it remodels the splenic immune microenvironment by expanding effector T cells and reducing immunosuppressive myeloid cell reservoirs, thereby inducing systemic anti-tumor immunity. We previously reported favorable safety and preliminary efficacy of αPD-1-Ery in patients with PD-1/PD-L1–resistant solid tumors. Here, we report long-term follow-up results assessing durability of benefit and exploratory biomarkers. **Methods:** 14 heavily pretreated patients with 11 types of advanced solid tumors who had progressed on PD-1/PD-L1–containing regimens as their most recent line of therapy were enrolled. Patients received αPD-1-Ery monotherapy at 2×10^{11} or 3×10^{11} cells. Endpoints included safety, efficacy, and exploratory correlations between immune biomarkers and clinical outcomes. **Results:** As of October 31, 2025, all patients had completed treatment, with a median follow-up of 18.9 months. Treatment discontinuation occurred due to disease progression in 57.1% (8/14), CR in 7.1% (1/14), completion of planned treatment cycles in 21.4% (3/14), and other reasons (including AE or withdrawal) in 14.3% (2/14). No DLTs were observed. TRAEs occurred in 64.3% (9/14) of patients, with no grade $>$3 TRAEs, no grade $\geq$3 immune-related AEs, and no treatment discontinuations due to TRAEs. αPD-1-Ery demonstrated sustained anti-tumor activity, with a DCR of 78.6% (11/14) and an ORR of 42.9% (6/14; 1 CR, 1 uCR, 4 PR), with improved responses observed in the higher-dose cohort. mPFS was 5.6 months and mOS was 23.4 months. Durable benefit was observed in most responders, with 4/6 maintaining response after treatment discontinuation; 1 received no subsequent therapy and 3 resumed PD-1/PD-L1–based immunotherapy despite prior resistance. mDoR had not been reached (range, 4.8–24.7 months). Exploratory analyses indicated that clinical benefit was observed in both primary (n = 3) and acquired (n = 3) anti–PD-1/PD-L1–resistant patients. Responders had higher baseline circulating PMN-MDSCs and DCs and experienced rapid and sustained PMN-MDSC reduction following treatment. Tumor MMR status was available in 5 patients (all MSS), with objective responses observed in 3. **Conclusions:** Spleen-directed PD-1 blockade using erythrocyte–antibody conjugates induces durable clinical benefit. αPD-1-Ery represents a novel immunotherapeutic strategy for PD-1/PD-L1–resistant solid tumors and supports further clinical development. Clinical trial information: NCT06026605. Research Sponsor: None.

Single-cell multi-omics and TCR sequencing to identify early tumor cavity homing and phenotypic evolution of CAR-T cells in glioblastoma. First Author: Qi Zhu, 2nd Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has shown remarkable efficacy in hematological malignancies but remains largely ineffective in glioblastoma. A systematic understanding of early CAR-T cell trafficking and phenotypic adaptation within the tumor immune microenvironment may provide critical insights into this limitation. **Methods:** We performed single-cell multi-omics profiling using the 10x Chromium Single-Cell 5′ Immune Profiling platform on infused CAR-T cells and matched tumor cavity cerebrospinal fluid (CSF) obtained via an Ommaya reservoir at day 3 post-infusion. Paired transcriptome/TCR data enabled analyses of composition, clonal tracking, and phenotypic transitions within CAR-T populations following early tumor cavity homing. **Results:** Single-cell profiling of the infused CAR-T product revealed a T cell–dominant population, primarily composed of $CD8^+$ T cells (62.24%) and $CD4^+$ T cells (34.63%). Analysis of tumor cavity CSF demonstrated a heterogeneous immune landscape, including $CD4^+$ T cells (32.79%), $CD8^+$ T cells (20.83%), dendritic cells, monocyte/macrophage populations, and other innate immune subsets. Gene set variation analysis across all immune cell populations showed enrichment of memory-associated programs in the CSF, while exhaustion-related signatures were not prominent, indicating a relatively non-exhausted immune state at this early time point. TCR-based clonal tracking identified 188 CAR-T cells in the CSF that originated from the infusion product, corresponding to an early homing rate of 2.19%. These homed CAR-T cells were predominantly derived from cytotoxic and proliferating $CD8^+$ T cell subsets, as well as effector $CD4^+$ T cells. Notably, cytotoxic $CD8^+$ CAR-T cells exhibited pronounced clonal expansion in the CSF, whereas proliferating $CD8^+$ CAR-T cells underwent phenotypic transitions toward cytotoxic states following tumor cavity infiltration. In parallel, activated $CD4^+$ CAR-T cells preferentially adopted memory-like phenotypes. Consistently, TCR-tracked CAR-T cells in the CSF displayed significantly stronger memory-associated transcriptional signatures compared with their clonal counterparts in the infusion product (CSF vs. product, -0.187 vs -0.088 , $p = 2.48 \times 10^{-9}$). **Conclusions:** This study provides a single-cell and clonal-level view of early CAR-T cell trafficking and phenotypic adaptation within the glioblastoma tumor cavity. Early tumor cavity infiltration is a selective process driven by cytotoxic and proliferative CAR-T subsets and occurs in the context of preserved memory-associated programs with limited exhaustion. These findings suggest that the limited efficacy of CAR-T therapy in glioblastoma is likely to stem from barriers that emerge at later stages following initial tumor entry instead of immediate CAR-T dysfunction. Research Sponsor: None.

Rab11 family interacting proteins as regulators of T cell recognition and infiltration in triple negative breast cancer. First Author: Paras R. Sahani, Rosalind Franklin University of Medicine and Science, North Chicago, IL

Background: Triple negative breast cancer (TNBC) accounts for 10-15% of all breast cancer cases and has the worst prognosis (5 year relative survival rate of 78%). TNBC is defined by absent estrogen and progesterone receptors and lack of HER2 amplification. First-line treatment for metastatic TNBC has evolved in the past several years to include immunotherapy for PD-L1+ patients. Recent NCCN guidelines recommend antibody-drug conjugate (ADC) therapy as first line treatment for metastatic TNBC regardless of PD-L1 positivity. ADCs target cell surface proteins that are abundant on tumors and sparse on healthy cells, delivering cytotoxic payloads selectively to the tumor. ADC efficacy depends on surface localization of target antigens, whose localization is dictated by endosomal trafficking via Rab GTPases. We showed that Rab11b-mediated endosomal trafficking is required for breast cancer brain metastasis. Here we investigate how trafficking-mediated control of the cell surface dictates immune recognition and response. **Methods:** Using a CRISPR screen we found that Rab11 family interacting proteins, Rab11fip2 and Rab11fip3, are required for immunogenic breast cancer cells to be recognized by CD8+ T cells. Flow cytometry revealed that the loss of recognition is not due to changes in surface PD-L1 or MHC/antigen presentation. Knockout of either Rab11fip did not change cell proliferation or tumor burden in immunocompromised animals, but led to significantly increased tumor growth in immunocompetent animals. This suggests that knockout of either Rab11fip causes loss of immune recognition to allow faster tumor growth while control tumors are restrained by the immune system. IHC analysis revealed a significant decrease of tumor infiltrating T cells in Rab11fipKO tumors. Interestingly, immune disruption is systemic, as splenic architecture is disrupted in Rab11fipKO tumor bearing mice. **Results:** Since the primary function of Rab11fips is to mediate trafficking of Rab11 cargo proteins, our results suggest that surface localization of these cargo proteins is required for immune cell recruitment, recognition, or activation. **Conclusions:** We are currently focused on identifying these cargo proteins, determining whether Rab11 controls trafficking of Trop-2 the target of several current ADCs, and characterizing Rab11 control of the T cell-cancer cell interaction in human breast cancer cell lines. Our work holds the promise of finding novel targets for ADCs and biomarkers for responsiveness to immunotherapy. Long-term follow-up of satricabtagene autoleucel (satri-cel) as sequential therapy after first-line treatment for advanced gastric cancer: A subgroup analysis. First Author: Chang Liu, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Early Drug Development Centre, Peking University Cancer Hospital & Institute, Beijing, China

Background: Claudin18.2 (CLDN18.2) has emerged as a new target for the treatment of gastric cancer in the first-line (1L) setting with the approval of zolbetuximab. This long-term analysis reports the extended efficacy and safety of satri-cel (autologous CLDN18.2-specific CAR T cells) as sequential therapy after 1L treatment in patients with advanced gastric/gastroesophageal junction (G/GEJ) cancer, after the results of all cohorts published in 2024 (Qi C, et al. Nat Med. 2024;30(8):2224-2234. NCT03874897). **Methods:** This trial is an open-label, multi-cohort, phase 1 trial, which evaluated the safety and efficacy of satri-cel in patients with CLDN18.2-positive advanced gastrointestinal cancers. Cohort 3 in dose-expansion stage enrolled patients with advance G/GEJ cancer and were given satri-cel as sequential treatment after 1L therapy. The primary endpoint was safety; secondary endpoints included efficacy, pharmacokinetics and immunogenicity. **Results:** As of October 18, 2025, 5 patients with CLDN18.2-positive G/GEJ cancer received satri-cel infusion(s) of 250×106 cells, sequentially after 1L therapy. Each patient received a total of one (n=1), two (n=1), and three doses (n=3) of satri-cel. Patients had received a median of 5 cycles (range, 4-11) of 1L chemotherapy before satri-cel infusion, with 1 (20%) treated with PD-1 inhibitor. Notably, only 1 patient achieved PR after first-line therapy. Three patients (60%) were Lauren diffuse type and 1 (20%) with mixed type, 4 (80%) had signet ring cell carcinoma, and 4 (80%) had peritoneal metastases. Median follow-up from initial 1L therapy was 54.6 months (reverse KM, 95% CI: 51.1, NE). Among 4 patients with target lesions, confirmatory objective response rate was 100%, and median duration of response was not reached. One has maintained SD for 20.9 months and 2 received surgical resection after satri-cel therapy. Median progression-free survival and median overall survival since 1L therapy was 20.9 months (95% CI: 10.8, NE) and 22.1 months (95% CI: 10.8, NE), respectively. Two were still alive as of cutoff date, with a follow-up of 58.1 months and 51.1 months. Safety was manageable. No grade 3 or higher cytokine release syndrome (grade 1: n=1, 20%; grade 2: n=4, 80%), any grade immune effector cell-associated neurotoxicity syndrome, or treatment-related deaths occurred. Despite common hematologic toxicities, no severe infections (grade $\geq$3) or febrile neutropenia were reported. **Conclusions:** With an extended follow-up exceeding 4.5 years, satri-cel as first-line sequential treatment continues to demonstrate durable survival benefit with a manageable safety profile in patients with advanced G/GEJ cancer, supporting its highly promising potential in earlier lines of therapy. Clinical trial information: NCT03874897. Research Sponsor: None.

Concurrent chemoradiotherapy plus cytokine-induced killer cells therapy or observation in patients with locoregionally advanced nasopharyngeal carcinoma: A ten-year follow-up of a randomized, phase II study. First Author: Xiuyu Cai, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China

Background: Concurrent chemoradiotherapy (CCRT) is the standard of care for patients with locoregionally advanced nasopharyngeal carcinoma (NPC). We aimed to evaluate the efficacy and safety of Cytokine-Induced Killer cells (CIK) consolidation therapy in combination with CCRT in these patients. **Methods:** Patients with locoregionally advanced NPC were randomized in a 1:1 ratio to receive concurrent chemoradiotherapy therapy plus CIK consolidation therapy or concurrent chemoradiotherapy alone in this single-center, randomized, phase II study. The primary endpoints were disease-free survival (i.e., survival period free from disease recurrence [distant metastasis and/or locoregional recurrence] or death from any cause) and overall survival in the intention-to-treat population. Safety was a secondary endpoint. **Results:** 58 patients were enrolled in this study (29 in the CIK therapy group and 29 in the control group). The median follow-up time was 144.70 months. In the CIK therapy group, the 10-year disease-free survival rate was significantly higher than that in the control group (82.5% versus 61.3%; hazard ratio for recurrence or death, 0.258; 95% confidence interval [CI], 0.094-0.712; P=0.005). The 10-year overall survival rate was 86.2% and 67.5%, respectively; (hazard ratio for death, 0.377; 95% CI, 0.131-1.087; P=0.06). The main adverse effects of CIK was fever which resolved after symptomatic treatment. In the CIK therapy group, 23.1% of patients experienced acute adverse events of grade 3 or 4 versus 17.2% in the control group during CCRT. The most frequent adverse events of grade 3 are mucositis, followed by decreased appetite, marrow suppression. **Conclusions:** CIK consolidation therapy plus CCRT significantly improved disease-free survival in patients with locoregionally advanced NPC. (This trial is registered with Chinese CilnicalTrial.gov, number ChiCTR-TRC-08000262). Clinical trial information: ChiCTR-TRC-08000262. Research Sponsor: None.

Optimization of tumor-infiltrating lymphocyte (TIL) manufacturing in non-small cell lung cancer (NSCLC) using an IL-7/IL-15/IL-2 expansion protocol. First Author: Jorge Bartolome, Hospital Clinico San Carlos and IdISSC, Madrid, Spain

Background: Adoptive cell therapy with tumor-infiltrating lymphocytes (TILs) is a promising strategy in non-small cell lung cancer (NSCLC), although ex vivo expansion remains challenging due to variability in yield and product quality. Optimizing cytokine support during TIL expansion may improve manufacturing robustness while preserving a clinically relevant immunophenotype. **Methods:** Tumor tissue specimens were obtained from immediately resected NSCLC lesions and processed for TIL outgrowth and rapid expansion over 28 days using either standard IL-2 or an experimental IL-7/IL-15/IL-2 protocol. Manufacturing endpoints included expansion yield, viability and $CD3^+$ proportion. Multiparametric flow cytometry assessed memory differentiation subsets and exhaustion-associated markers at baseline, pre-REP and post-REP. Clinical-pathological variables included disease stage, PD-L1 expression and prior systemic treatment. **Results:** 11 NSCLC TIL expansions were analyzed (experimental: n=7; IL-2: n=4). Median age was 73.1 years (range 48.5–92.3) and ECOG was 0–1 in 91% of patients; 64% had early-stage disease and 27% had advanced-stage (III–IV). PD-L1 was $<$1% in 73%, 9% showed PD-L1 1–49%, and none $\geq$50%. The cohort included pretreated patients, including prior anti–PD-1 exposure. Compared with IL-2, IL-7/IL-15/IL-2 resulted in a modest reduction in expansion yield (15–28%) and a lower CD4+/CD8+ ratio (6.62 vs 19.86), but showed improved manufacturing robustness, with all expansions meeting predefined quality criteria, whereas standard IL-2 expansions showed more variable product quality. Immunophenotypic profiling showed a more stable memory-oriented differentiation pattern with IL-7/IL-15/IL-2, including reduced naïve and TEMRA subsets and increased CD4+ TCM cells; CD8+ TCM remained predominant in both protocols. A polarisation towards the effector memory phenotype ($CCR7^-CD45RA^-$) was observed in the experimental protocol. CD28 remained highly expressed in both protocols, while CD134 tended to decrease with IL-7/IL-15. During pre-REP, PD-1 and TIM-3 were reduced in several subpopulations under the experimental protocol, suggesting a transiently less exhausted phenotype. After REP, these differences disappeared, with comparable levels between protocols. During REP, Th1 and Tfh increased in both protocols, while Th2 and Th17 remained low. **Conclusions:** Supplementation with IL-7 and IL-15 during NSCLC-derived TIL expansion improves consistency of product quality and supports a favorable memory-oriented and functional phenotype without increasing exhaustion markers at the end of manufacturing. This approach may enable more reliable generation of clinically applicable TIL products in heterogeneous and pretreated NSCLC populations, facilitating broader implementation of TIL-based therapies. Research Sponsor: None.

2560 **Poster Session**

Preliminary phase 1 results of a MICA/B-targeted CAR T cell designed to overcome solid tumor escape mechanisms and avoid the requirement for conditioning chemotherapy. First Author: Manish Ramesh Patel, University of Minnesota Medical School, Department of Medicine, Division of Hematology, Oncology, and Transplantation, Minneapolis, MN

Background: FT836 is a multi-engineered CAR T cell targeting the conserved α3 domain of MICA/B stress ligands, enabling recognition of diverse solid tumors with additional edits including, (i) the hnCD16a FC receptor to enable multi-antigen targeting in combination with monoclonal antibodies (mAb), (ii) Sword and Shield engineering consisting of alloimmune-defense receptor (ADR) expression and CD58 deletion to coordinately avoid host recognition eliminating the need for conditioning chemotherapy (CCT), and (iii) CXCR2 and TGFβ signal redirection receptors to maximize tumor trafficking and adaptability within an immunosuppressive tumor niche, respectively. Manufactured from an iPSC-master cell bank, it is available off-the-shelf and delivered on-demand to patients (pts). **Methods:** The Phase 1 trial of FT836 in pts with advanced solid tumors (NCT07216105) evaluates multiple regimens including monotherapy (Regimen A), combination with EGFR-targeting mAb cetuximab or HER2-targeting mAb trastuzumab (Regimen C or E, respectively). CCT is not required and FT836 is given twice during the treatment cycle, with retreatment available for eligible patients. First dose of FT836 is administered with a 24-hour hospital stay while the 2^{nd} dose is given as outpatient. **Results:** First three pts (all MSS mCRC; median: age 45 y, prior therapies of 5, disease duration of 51 months) were treated in Regimen C dose level 1 (DL1 = 300 million cells/dose, Days 1 and 15 with cetuximab, no CCT) and completed dose limiting toxicity (DLT) evaluation (data cut-off 15 JAN 2026) with no DLTs, FT836-related serious adverse events, cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS), or graft-versus-host disease (GvHD) reported. One of the three pts demonstrated a CEA response with $>$50% reduction (480 ng/mL at BL; 230 ng/mL at 4 weeks after first FT836 infusion) that correlated to mass shrinkage in all target lesions in a week 7 CT scan (obtained after data cut-off date). Of the other two pts, one experienced PD while the other was not yet assessed at the time of abstract submission. FT836 was detected in peripheral blood (PB) following the first dose, with persistence observed up to 1 week. Notably, FT836 cells were detected beyond the initial PB detection in a tumor biopsy obtained at Day 22 ($\pm$3 days) indicating greater persistence in tissue compared to PB, supporting the value of additional engineered elements. EGFR and MICA/B antigens were identified in 3/3 baseline tumor biopsies, highlighting the relevance of multi-antigen targeting in driving patient outcome. **Conclusions:** FT836 Regimen C DL1 was well-tolerated and early clinical data supports anti-tumor activity in highly refractory mCRC where there is significant unmet need. This trial is actively enrolling and updated clinical and translational data will be presented. Clinical trial information: NCT07216105. Research Sponsor: Fate Therapeutics.

Extreme persistence of polyclonal $CD8^+$ CAR T cells as a driver of marrow failure, neurotoxicity, and fatal immune collapse after ciltacabtagene autoleucel. First Author: Djordje Atanackovic, University of Maryland Greenebaum Comprehensive Cancer Center, Baltimore, MD

Background: BCMA-directed chimeric antigen receptor (CAR) T-cell therapies induce deep responses in relapsed/refractory multiple myeloma (MM), but increasing potency has expanded the spectrum of treatment-related toxicities. While cytokine release syndrome and immune effector cell–associated neurotoxicity are well characterized, the consequences of extreme and prolonged CAR T-cell persistence remain poorly understood, particularly as CAR T-cell strategies are extended to solid tumors. **Methods:** We performed longitudinal, multi-compartment immunomonitoring in a patient with high-risk MM treated with ciltacabtagene autoleucel (cilta-cel) who developed an unusual leukemia-like clinical course. Peripheral blood (PB), bone marrow (BM), and cerebrospinal fluid (CSF) samples were analyzed by multiparameter flow cytometry, functional cytokine secretion assays, multiplex cytokine profiling, single-cell RNA sequencing with paired T-cell receptor (TCR) repertoire analysis, and lentiviral CAR integration site mapping. **Results:** Following cilta-cel infusion, the patient developed massive and persistent expansion of non-malignant $CD8^+$ effector-memory CAR T cells, comprising $>$90% of circulating lymphocytes and ~95% of BM lymphocytes, with absence of detectable non-transduced T cells. Despite achieving complete remission of MM, extensive BM infiltration by CAR T cells was associated with marked marrow hypocellularity, trilineage hypoplasia, and prolonged pancytopenia. A distinct trafficking-competent $CD8^+$ effector-memory subset (TEM5) was selectively enriched in CSF and associated with severe neurotoxicity and a local pro-inflammatory cytokine milieu. Single-cell transcriptomics demonstrated a highly migratory, cytotoxic effector program with suppressed proliferation, MAPK/TCR signaling, and tissue-residency signatures. TCR repertoire and integration site analyses confirmed polyclonality and excluded malignant transformation or insertional oncogenesis. Sustained CAR T-cell dominance coincided with profound hypogammaglobulinemia, failure of immune reconstitution, recurrent life-threatening infections, and ultimately fatal sepsis. **Conclusions:** These findings define a previously underrecognized toxicity paradigm of BCMA CAR T-cell therapy characterized by pathologic immune dominance and extreme persistence of cytotoxic CAR T cells, leading to marrow failure, neurotoxicity, and lethal immunosuppression. Extended multi-parametric immunomonitoring may identify patients at risk and inform risk-adapted management strategies, and this principle has potential implications for the design of next-generation CAR T-cell therapies, including for solid tumors. Research Sponsor: None.

Influence of onboard, tethered IL-12 on potency of the Tmod NOT gate and selectivity. First Author: Jushen Liang, A2 Biotherapeutics, Agoura Hills, CA

Background: To realize the full therapeutic potential of engineered immune cells in solid tumors, high potency must be coupled with absolute selectivity. While synthetic NOT logic gates, such as the LIR-1 NOT gate (Tmod) system, effectively address non-specific cytotoxicity, overcoming the suppressive tumor microenvironment (TME) requires auxiliary stimulation. This study focused on Interleukin-12 (IL-12)—a potent pro-inflammatory cytokine—as an "armoring" strategy to bridge this gap. **Methods:** We designed an antigen-inducible, membrane-tethered IL-12 system to boost antigen-specific Tmod activity. The performance of this inducible IL-12 construct was evaluated across various long-term in vitro and in vivo assays to measure Tmod T cell exhaustion (specifically the upregulation of PD-1 and downregulation of CD62L) and its ability to mitigate the immunosuppressive effects of TGFβ, a primary barrier in the solid tumor microenvironment. We further assessed the reversibility of IL-12 expression upon antigen clearance and monitored for IL-12 shedding both in vitro and in vivo. **Results:** The inducible IL-12 construct boosted antigen-specific Tmod activity, prevented T cell exhaustion, and effectively mitigated the immunosuppressive effects of TGFβ that typically hamper CAR-T persistence. Crucially, this potency boost did not "override" the LIR-1 blocker; the IL-12-enhanced cells remained selective, sparing normal cells. Furthermore, data showed that the expression of membrane-tethered IL-12 is reversible once the antigen is cleared. Minimal IL-12 shedding was observed, suggesting the pro-inflammatory signal remained localized to the immunological synapse. **Conclusions:** The antigen-inducible membrane-tethered IL-12 system enhances Tmod potency while maintaining a high degree of selectivity and an acceptable safety profile for clinical translation. An Investigational New Drug (IND) application for MSLN-targeted Tmod boosted by antigen-inducible membrane-tethered IL-12 has been approved by the FDA, and a Phase 1 clinical trial is currently ongoing. Research Sponsor: None.

Novel transposon BAFF CAR-T cells (LMY-920) for non-Hodgkin lymphoma (NHL). First Author: Paolo Fabrizio Caimi, Cleveland Clinic, Cleveland, OH

Background: CAR-T cells targeting CD19 using scFv-based CARs have been effective and approved to treat lymphoma. Response rates are high, but a significant number of patients fail to respond or relapse. This has been linked to T cell exhaustion, immune dysregulation, and/or epitope loss. To overcome this, we developed a CAR-T cell product expressing a BAFF-ligand (LMY-920). The CAR consists of truncated human BAFF on a 3rd generation CAR backbone with CD28, OX40, and CD3z intracellular signaling domains. The BAFF-ligand domain confers ability to bind the 3 BAFF receptors (BAFFR/BR3, TACI and BCMA). These are attractive tumor-associated antigens being variably expressed in all B-lineage malignancies such as B cell NHL, chronic lymphocytic leukemia (CLL), hairy cell leukemia and multiple myeloma (MM), and are important for B-cell survival, reducing the chance of antigen escape. Additionally, they are expressed on B-lineage cells involved in antibody-mediated autoimmune diseases. BAFF ligand interactions are lower affinity than scFv interactions, potentially reducing T-cell exhaustion. The novel *TcBuster* transposon system is used to improve manufacturing time, efficiency, cost, and safety. **Methods:** Patients with refractory B cell NHL are treated in this study (NCT05312801). Autologous LMY-920 CAR-T cells are manufactured, then patients receive 3 days of fludarabine (30 mg/m^2/d) and cyclophosphamide (500 mg/m^2/d) lymphodepletion. LMY-920 is administered intravenously in a 3+3 dose escalation design from 1-8 x 10^6 BAFF-CAR-T cells/kg. Response is assessed using the Lugano criteria. CAR-T expansion and biologic characteristics are assessed. **Results:** Five patients have been treated with 1-2 x 10^6 BAFF-CAR-T cells/kg in this study, 2 patients each with mantle cell lymphoma (MCL), diffuse large B cell lymphoma (DLBCL), and one with marginal zone lymphoma (MZL). Patients had received 2 – 6 prior lines of therapy and all were refractory. One patient experienced grade 1 CRS (fever), but no ICANS was reported. All patients experienced grade 3 or higher hematologic toxicity that recovered prior to day 28, and grade 1-2 fatigue. There have been no dose limiting toxicities and dose escalation continues. Responses included 2 complete responses (CR) (DLBCL), a partial response (MZL), a mixed response (MCL) and one stable disease (MCL). Of note, one of the DLBCL patients in CR had received prior axicabtagene ciloleucel (anti-CD19) CAR-T cells as well as anti-CD20 bispecific antibodies, with lymphoma cells resulting in CD19 and CD20 antigen loss. **Conclusions:** The successful use of a novel transposon-engineered BAFF ligand-based CAR-T cell product demonstrates the potential of a new direction in CAR-T cell development. Safety and efficacy were seen, including patients with prior CAR-T failure and epitope loss, as hypothesized. This product is also being evaluated in patients with CLL, MM and systemic lupus erythematosus. Clinical trial information: NCT05312801. Research Sponsor: Luminary Therapeutics.

Depletion of T-regulatory cells by denileukin diftitox-cxdl (E7777) in combination with pembrolizumab in relapsed/refractory (r/r) gynecologic malignancies: Phase 1 study results. First Author: Haider Mahdi, Magee-Womens' Hospital of UPMC, Pittsburgh, PA

Background: Denileukin diftitox-cxdl (E7777) is an FDA-approved direct cytotoxic agent that depletes T-regulatory cells by targeting the IL-2 receptor. Pre-clinical studies have demonstrated synergistic activity between the immunomodulator E7777 and PD-1 immune checkpoint inhibitor (ICI). Here, we report positive results from a phase I study of E7777 + pembrolizumab (P) in r/r gynecological (GYN) malignancies. **Methods:** Phase I dose-escalation trial of E7777 given at 4 IV dose levels (DL): 3, 6, 9, and 12 mg/kg on days 1-3, combined with P (IV 200 mg, day 1) in a 21-day cycle x8, followed by maintenance P until progression. Dose-limiting toxicities (DLTs) were assessed during cycle 1 according to CTCAE v5 criteria. Responses were measured using the RECIST 1.1 criteria. Blood samples were collected for translational studies. **Results:** Pt demographics included: median age 64y (43, 88); race, 88% white; histology 40% endometrial, 36% ovarian. Of the 24/25 pts evaluable for DLTs, only 1 case of reversible capillary leak syndrome (CLS) was seen at DL4. Anemia, fatigue, chills, and hypoalbuminemia were the most common AEs. A comprehensive overview of AEs, SAEs, and immune-related adverse events (irAEs) will be presented at the annual meeting. Table 1 describes the 4 DLs and their responses in the 21 pts evaluable for efficacy. An ORR of 24% (5 PRs) was reported in this heavily pretreated patient population with a mDOR of 21.1m (4.2-35.0). E7777 + P responses were seen in patients who progressed on prior ICI therapy, and across different GYN histologies. The median Progression-free survival (mPFS) was 5.8 m (1.1 – 37), with 5 pts having a PFS of ≥20 months. The clinical benefit rate (CR; PR; SD ≥ 6 m) was demonstrated in 48% of pts (n=10), who achieved a mPFS = 17.4m (6.2 – 37); patients with documented PD had a mPFS = 2.1 m (1.1 – 4.7). **Conclusions:** The results from this Phase I study of two immunomodulatory agents in combination, E7777 + P, in patients with r/r GYN tumors was well tolerated and demonstrated promising efficacy. A max tolerated dose wasn't established. No new significant safety signals or irAEs were reported. ORR of 24 % was demonstrated. Responders achieved a mDOR of 21.1m (4.2 - 35.0) and a mPFS = 23 m (10.4 – 37.0). Thus, E7777 + P showed prolonged responses and clinical benefit in pts with r/r GYN malignancies and limited options. These results will inform a Phase II study. Clinical trial information: NCT05200559. Research Sponsor: Citius Oncology Inc.

Transposon-engineered hypoxia-inducible T cells for treatment of solid tumors. First Author: Yannick Schreiber, Northwestern University, Evanston, IL

Background: Engineered cell therapies expressing a chimeric antigen receptor (CAR) in human T cells have demonstrated significant promise for the treatment of hematological malignancies. However, translating CAR T cell therapies to solid tumors remains challenging due to two limitations: (1) specificity, as few antigens are truly unique to solid tumors, leading to off-target toxicities; and (2) suppression, as solid tumors establish immunosuppressive microenvironments that limit T cell survival and cytotoxicity. To address these challenges and improve the safety and potency of solid tumor cell therapies, we engineered cells with synthetic circuits designed to amplify hypoxia-induced signaling through feedback and synthetic transcriptional control, enabling augmented and tunable responses within both modestly and profoundly hypoxic environments. **Methods:** We evaluated circuit architectures in HEK293FT cells in which the HBS promoter drove either native HIF transcription factors or synthetic transcription factors and promoters controlling a fluorescent reporter. Circuits were stably integrated using PiggyBac transposon vectors, and cells were cultured under normoxic (21% O_2), modestly hypoxic (5% O_2), and profoundly hypoxic (1% O_2) conditions. Fluorescent reporter expression was quantified by flow cytometry over three days, and candidate circuits exhibiting high-output, low-background expression under hypoxia were identified. These candidate circuits were subsequently introduced into primary human T cells using transposon vectors. CAR expression in engineered T cells was measured by flow cytometry after culture for three days in modest or profound hypoxia, and cytotoxic activity was assessed in co-culture assays with BT-474 breast cancer and SKOV3 ovarian cancer cells. **Results:** We identified novel circuit architectures that produced rapid induction with minimal background under hypoxia and defined design rules governing transgene amplification. Circuit topologies incorporating synthetic transcription factor–mediated feedback exhibited markedly amplified expression relative to native HIF-based circuits. CAR-expressing T cells demonstrated cytotoxic activity compared with unmodified T cells in co-culture assays. **Conclusions:** We present a therapeutic platform that enables hypoxia-dependent sensing and high-output control of therapeutic gene expression within solid tumor microenvironments. This approach has the potential to improve the safety and efficacy of engineered cell therapies for solid tumors and to provide mechanistic insights that inform the development of hypoxia-responsive cell therapies. Targeting MAN1A1 to address immune checkpoint inhibitors resistance: A novel mechanism of vascular-endothelial reprogramming in NSCLC. First Author: Ai Gao, Tianjin Medical University General Hospital, Tianjin, China

Background: Despite the efficacy of immune checkpoint inhibitors (ICIs) in NSCLC, resistance remains a major hurdle. The role of non-immune components, particularly vascular endothelial cells (VECs), is poorly understood. We aimed to identify key drivers of ICI resistance by focusing on VEC-mediated remodeling of the tumor microenvironment (TME). **Methods:** We integrated transcriptomic data from public cohorts of ICI-treated and treatment-naïve NSCLC patients (GSE225620), proteomic profiling from in-house whole blood samples, and peripheral blood lymphocyte subset analysis from NSCLC patients and healthy controls. Differential expression analysis and machine learning (LASSO, SVM-RFE) were employed to identify key resistance-associated genes, including MAN1A1. Functional validation was performed using shRNA-mediated MAN1A1 knockdown in A549 and H1299 NSCLC cell lines, with apoptosis measured by flow cytometry. Single-cell RNA-seq data (GSE207422) from pre- and post-treatment NSCLC tumors were analyzed using Seurat for cell annotation. Cell-cell communication (CellChat) and pathway activity (AUCell) analyses were used to investigate VEC-immune cell interactions and their association with treatment response. Statistical analyses included Kaplan-Meier survival, Cox regression, and ROC curves to assess the prognostic and predictive value of MAN1A1. **Results:** Multi-omics analysis identified MAN1A1 as a key candidate associated with ICI resistance. Elevated MAN1A1 expression predicted inferior clinical outcomes, including shorter mPFS (3.2 vs. 8.5 months; P=0.019) in our cohort and reduced OS (47.4 vs. 65.1 months; HR=0.95, P=0.017) in the TCGA dataset. MAN1A1 expression effectively distinguished ICI non-responders (AUC=0.784). MAN1A1 knockdown significantly induced apoptosis in NSCLC cell lines (A549, P=0.00022; H1299, P=0.0004). Increased peripheral B-cell counts post-chemotherapy correlated with treatment response, and MAN1A1 protein levels inversely associated with B-cell levels (r=-0.38, P$<$0.05). Single-cell RNA-seq analysis revealed VECs as the primary expressors and communication hubs of MAN1A1. In non-responders, MAN1A1-high VECs were reprogrammed to drive a pro-inflammatory feedback loop with neutrophils via ANXA1-FPR1/NAMPT-integrin signaling axes. In contrast, VECs from responders exhibited a shift towards T-cell-recruiting LGALS9-CD45 signaling. **Conclusions:** Our study identifies MAN1A1 as a novel driver of ICI resistance in NSCLC, mediating vascular-endothelial reprogramming that fosters an immunosuppressive TME characterized by pro-tumor neutrophil recruitment and impaired T- and B-cell immunity via the ANXA1-NAMPT axes. Targeting MAN1A1 represents a promising therapeutic strategy to overcome ICI resistance, providing a strong rationale for future translational development. Research Sponsor: None.

Circulating extracellular vesicles carrying PD-1, PD-L1, and CTLA-4 to inform resistance to immunotherapy in HCC. First Author: Joao Gorgulho, Department of Oncology, Hematology and Bone Marrow Transplantation with Section of Pneumology, University Medical Centre Hamburg-Eppendorf, Hamburg, Germany

Background: First-line immune checkpoint inhibitor (ICI) therapy has contributed to improved outcomes in hepatocellular carcinoma (HCC). However, only around 30% of patients respond, highlighting the need for biomarker driven patient selection. Considering the lack of tissue acquirement in HCC in clinical routine, liquid biopsy holds great promise. In this study, we aimed at profiling immune checkpoints (IC) on circulating extracellular vesicles (EVs) as potential liquid biopsy-based biomarkers for prediction of treatment response. **Methods:** Three distinct cohorts were analyzed in this study: (1) *HCC Explorer Cohort* (n=40), testing the presence of membrane-bound ICs on EVs; (2) *early-stage HCC Cohort* (n=37 with paired blood and tissue), assessing the interplay between EV and tissue ICs alongside clinicopathological parameters and (3) *Treatment Cohort* (n=161 with 548 sequential blood samples), comprising a training (n=79,n=402 sequential samples) and a validation group (n=82, n=146 sequential samples), to identify predictors of immunotherapy response through IC profiling of circulating EVs via multiplex immunoassay. **Results:** PD-1, PD-L1 and CTLA-4 were enriched in EVs compared to EV-depleted serum. Baseline and early dynamics in EV-IC levels significantly discriminated between responders and non-responders in the training and validation cohort, while simultaneously predicting PFS and OS. In addition, dynamic changes of EV-IC levels during therapy in patients with initial response predicted acquired therapeutic resistance, approximately 36-42 weeks before progression was traceable on imaging. High serum EV-IC levels correlated with "cold" tumor features on paired tissue samples and single-EV profiling revealed various cells of origin of our EV-IC, e.g., PD-L1+ EV mainly derived from hepatocyte/HCC cells and antigen presenting cells, and PD-1+ EV mainly from T-cells and macrophages, as expected. **Conclusions:** EVs carrying PD-1, PD-L1 and CTLA-4 represent readily quantifiable, non-invasive biomarkers to predict response and survival in advanced HCC patients undergoing ICI therapy and serve to identify biological ICI resistance much earlier than current standards with imaging. Research Sponsor: None.

Baseline peripheral blood activated-to-total CD8$^+$ central memory T cell ratio to identify melanoma patients at high risk for severe toxicity but limited clinical benefit. First Author: Magdalena Kovacsovics, Huntsman Cancer Institute at The University of Utah, Salt Lake City, UT

Background: Immune-related adverse events (irAEs) represent a major clinical challenge that limits the usage of immune checkpoint blockade (ICB) for cancer therapy. The occurrence of irAEs often correlates with improved therapeutic response to ICB therapy, creating a therapeutic dilemma. Many known irAEs predictors correlate with treatment efficacy, further complicating clinical decision-making. Biomarkers that decouple severe irAEs risk from therapeutic benefit are thus urgently needed to guide clinical decision-making. **Methods:** We performed comprehensive peripheral blood immune profiling in two HCI (Huntsman Cancer Institute) clinical cohorts with 201 melanoma patients treated with ICB, analyzing 488-626 immune cell subsets and 1,463-2,926 plasma proteins at two timepoints: pretreatment and 3-6 weeks on therapy. Activated CD8+ T central memory (CD8Tcm) cells were defined by the expression of CD38, HLA-DR, or Ki67. Associations with severe irAEs, survival and treatment outcomes were evaluated across the largest test cohort composed of nine independent, multi-institutional clinical cohorts, two HCI cohorts, five Swiss cohorts, and two publicly available datasets. **Results:** Elevated pretreatment activated-to-total CD8+Tcm ratio robustly predicts severe irAEs. Patients with high versus low activated-to-total CD8+Tcm ratio showed two-fold or higher odds of developing severe irAEs across nine independent melanoma cohorts. Remarkably, this immune signature is associated with worse patient survival following ICB. These results suggest that there is a dedicated toxicity predictor in the peripheral blood. Incorporation of pretreatment plasma CXCL9 levels into a machine-learning regression model further improved irAEs predictive performance (mean AUC=0.78 across four independent cohorts). These baseline biomarkers outperformed previously reported irAEs predictors. **Conclusions:** The pretreatment activated-to-total CD8+Tcm ratio, alone or in combination with plasma CXCL9, identifies melanoma patients at high risk for severe irAEs who are not likely to respond to ICB treatment. This first of blood-based biomarker was tested and validated on many independent patients' cohorts and will allow to select patients based on the risk stratification prior to treatment initiation. Impact of eftilagimod alfa, an APC activator via MHC class II, on lymphocyte activation and survival outcomes in metastatic cancer patients. First Author: Martin David Forster, UCL Cancer Institute / University College London Hospitals NHS Foundation, London, United Kingdom

Background: Immune activation is important for survival in cancer. Eftilagimod alfa (E), an antigen-presenting cell (APC) activator, binds to a subset of MHC class II molecules on APCs to mediate lymphocyte, e.g. T cell (CD4/CD8), recruitment/activation. Clinical studies of E in combination with a PD-1 antagonist (P) or chemotherapy (C) have shown promising results in phase 2 studies, and E is currently investigated in a phase 3 study in combination with P and C in first-line NSCLC (NCT06726265). We present cumulative correlation studies of immune activation in blood after administration of E with clinical efficacy in late-stage cancer patients (pts). **Methods:** Five (5) studies with 569 pts were evaluated. 30 mg E in combination with either P (pembrolizumab IV at 200 mg q3w or 400 mg q6w or 2 mg/kg q3w) or C (paclitaxel 80 mg/m^2 day 1, 8, 15, q4w) was administered SC biweekly for 6 months (mo), then every 2-4 weeks for 6-18 mo in pts with late-stage metastatic NSCLC, HNSCC, melanoma, or breast cancer. Absolute lymphocyte count (ALC) was taken before dosing (day 1 per cycle). ALC response was pre-defined as a change $\geq$0.2 x 10^9/L in $\leq$3 mo on study. Samples for gene expression profile (GEP) were taken pre-dose / 3 mo in a subset (N=111). IFN-g and CXCL10 were assessed pre-dose / after 1st E admin in a subset (N=79). Clinical efficacy was assessed by iRECIST and survival. **Results:** Treatment with E led to a rapid (3 mo) and sustained (~12 mo) stat. sign. (p=0.03) ALC gain versus control arm. 54.4% of all pts treated with E were ALC responders (53.6% for E+P; 55.1% for E+C). In ALC responders with E, overall survival (OS) was significantly improved (see Table 1) compared to non ALC responders. Effects were observed irrespective of the combination partner, P or C, with a median increase of 6.8 or 5.2 mo, respectively. In pts treated with P or C alone (control), 40.4% were ALC responders but with no sign. median OS gain. Clinical responders (iPR or iCR as BOR) exhibited consistent upregulation of immune pathways associated with T-cell functions, NK cell functions and cytotoxicity during treatment in GEP analysis. These functions were not upregulated in non-responders. IFN-g and CXCL10 concentrations increased quickly (~8h) and significantly post-first E dosing compared to baseline and levels remained elevated until next E dosing. This effect with E was consistent with P or C. **Conclusions:** E leads to immediate and sustained ALC increase and TH1 type reaction, which is associated with clinical efficacy in combination with P or C. Research Sponsor: None.

Treatment	Effects	Results
E (N=408)	ALC Responder with E	54.4% (N=222/408)
	Impact on survival: ALC responder vs. ALC non-responder	Median OS+ 7.7 mo(23.4 vs.15.7 mo) HR=0.69; p=0.002
Control arm (N=161)	ALC Responder in control arm	40.4% (N= 65/161)
	Impact on survival: ALC responder vs. ALC non-responder	Median OS+2.9 mo(20.4 vs. 17.4 mo) HR=0.98; p=0.93

2570 Poster Session

Effects of a multimodal TCR/BCR repertoire foundation model on blood RNA-seq–based prediction of severe adverse event risk and rheumatoid arthritis. First Author: Anatoly Bobe, BostonGene Corporation, Waltham, MA

Background: Severe immune-related adverse events (irAEs) limit the use of immune checkpoint inhibitors (ICIs). Clinically, irAEs can resemble autoimmune diseases such as rheumatoid arthritis (RA), suggesting shared dysregulation of adaptive immune receptor repertoires (T-cell receptor [TCR] and B-cell receptor [BCR]). We developed a TCR/BCR foundation model to predict severe irAE risk prior to ICI treatment and to detect RA from peripheral blood. **Methods:** Peripheral blood RNA sequencing (RNA-seq) from cancer patients prior to ICI therapy, healthy donors, and RA patients was analyzed across six cohorts (Table 1). Severe irAEs were defined as grade $\geq$3. Gene expression quantification and signature scores were computed using kallisto and ssGSEA. Adaptive immune receptor repertoire (AIRR) features for TCR and BCR were derived from blood RNA-seq using an in-house pipeline (pyigmap). We trained neural network models to (i) estimate severe irAE risk in ICI-treated cancer patients and (ii) distinguish RA from healthy donors, using TCR/BCR embedding features alone or combined with gene signature scores. Performance was evaluated across multiple datasets to assess discrimination and cross-cohort robustness. **Results:** The model combining TCR/BCR embedding features with gene signature scores achieved improved discrimination for severe irAE risk prediction (AUC 0.78; $p=1\times10^{-5}$) and RA detection (AUC 0.70; $p=5\times10^{-14}$). This outperformed models based on gene signatures alone (irAE AUC 0.67; $p=8\times10^{-3}$; RA AUC 0.66; $p=4\times10^{-9}$), TCR/BCR diversity alone (irAE AUC 0.66; $p=2\times10^{-2}$; RA AUC 0.61; $p=6\times10^{-5}$), or signatures plus diversity (irAE AUC 0.70; $p=2\times10^{-3}$; RA AUC 0.69; $p=9\times10^{-13}$). Embedding-based representations were more robust to technical variation than conventional diversity metrics: batch-effect decomposition showed higher biological variability (0.012 vs 0.002) and lower technical variability (0.460 vs 0.861) for embeddings versus diversity features, consistent with improved cross-cohort generalization. **Conclusions:** A TCR/BCR foundation model integrated with gene signatures improves pre-treatment prediction of severe irAE risk and detection of autoimmune disease from peripheral blood RNA-seq. These repertoire-informed representations capture clinically relevant clonotype biology and support minimally invasive risk stratification and monitoring for patients receiving ICIs. Research Sponsor: None.

Exploratory biomarker analysis of ociperlimab (OCI) plus tislelizumab (TIS) in patients (pts) with PD-L1–positive non–small cell lung cancer (NSCLC) in AdvanTIG-105. First Author: Yan Yu, Harbin Medical Cancer Hospital, Harbin, Heilongjiang, China

Background: OCI (anti-TIGIT) plus TIS (anti-PD-1) may enhance antitumor immune responses in advanced solid tumors. We present a retrospective biomarker analysis of pts in AdvanTIG-105 (NCT04047862), a phase 1/1b open-label study of OCI plus TIS for treatment-naïve metastatic non-squamous (NSQ) and squamous (SQ) PD-L1-positive (TC $\geq$1%) NSCLC. **Methods:** Pts in cohort 3 (n=46) were treated with 900 mg OCI plus 200 mg TIS. Pts in cohort 10 (n=68) were treated with 450 mg (Arm A), 900 mg (Arm B), or 1800 mg (Arm C) OCI plus 200 mg TIS. Baseline tumor tissue was used to measure PD-L1 and TIGIT expression (SP263 and SP410 IHC assays). Gene expression profiling (GEP) was performed using TrueSeq RNA Access (Illumina); gene signature scores were evaluated with ssGSEA. Progression-free survival (PFS) hazard ratio (HR) was calculated by Cox proportional hazards regression. **Results:** At Aug 2024 data cutoff, median follow-up was 19.7 months (range: 0.7-41.6 mo) for cohort 3 and 9.8 mo (range: 0.3-21.4 mo) for cohort 10. Baseline characteristics, overall response rate (ORR), and PFS were comparable across cohorts and between biomarker-evaluable and intent-to-treat (ITT) pts. PD-L1 $\geq$25% vs $<$25% and TIGIT $\geq$5% vs $<$5% subgroups were associated with a trend toward higher ORR and longer PFS, with greater increment in pts with NSQ- vs SQ-NSCLC (Table). PD-L1/TIGIT double high subgroup showed further enriched clinical efficacy in NSCLC (Table). Anti-TIGIT mechanism of action-related GEP signatures (NK cells, Treg, macrophages) were associated with a trend toward longer PFS primarily in pts with NSQ-NSCLC. **Conclusions:** Pts with NSCLC with PD-L1 $\geq$25%, TIGIT $\geq$5%, or PD-L1/TIGIT double high can achieve a trend toward longer PFS and higher ORR than PD-L1 low or TIGIT low subgroups when treated with OCI plus TIS. Longer PFS in PD-L1 $\geq$25% or TIGIT $\geq$5% subgroups in NSQ- vs SQ-NSCLC may be associated with biological differences in histology. Confirmation of these results will require prospective evaluation of OCI plus TIS in randomized studies. Clinical trial information: NCT04047862. Research Sponsor: BeOne Medicines Ltd.

Molecular progression defined by longitudinal ctDNA dynamics for prediction of outcomes in immune checkpoint inhibitor–treated solid tumors. First Author: Muhammad Anees, Allegheny Health Network Cancer Institute, Allegheny Health Network, Pittsburgh, PA

Background: Reliable early biomarkers of immune checkpoint inhibitor (ICI) resistance remain an unmet need due to delayed imaging and non-classical response kinetics. While ctDNA has shown promise, current methods often require tumor tissue or rely on static comparisons. We investigated whether longitudinal ctDNA dynamics measured using a tumor-naive, methylation-based assay could define molecular progression and predict outcomes in patients receiving ICIs. **Methods:** Patients with advanced solid tumors treated with ICI regimens were analyzed in a primary cohort (n=65) with serial plasma sampling. Tumor Methylation Scores (TMS) were generated using Northstar Response. Molecular progression based on ctDNA trajectory was assessed for associations with PFS and OS and compared with conventional landmark ctDNA approaches and RECIST v1.1. Independent validation was performed in a second cohort (n=72). **Results:** Molecular progression strongly stratified survival in the primary cohort (OS HR=4.9, $p<0.001$; PFS HR=5.3, p=0.0002) and demonstrated superior prognostic performance relative to RECIST. These results were independently validated (PFS HR=4.6, p=0.00004; OS HR=4.3, p=0.005). Notably, among RECIST-defined non-progressors at 6 months, molecular progression identified patients with markedly worse outcomes (PFS HR=6.7, p=0.002; OS HR=4.5, p=0.011). Molecular progression preceded radiographic and clinical progression by median lead times of 63.5 and 77 days, respectively. **Conclusions:** Longitudinal ctDNA dynamics measured using a tumor-naive methylation assay define molecular progression that robustly predicts survival and identifies early ICI resistance, including in RECIST-stable patients. This approach offers clinically meaningful lead time and supports integration of ctDNA dynamics into response assessment frameworks for immunotherapy. Research Sponsor: None.

Molecular pathways of immune checkpoint inhibitor–induced hepatitis. First Author: Erika Bushatsky, Department of Medicine, Division of Oncology, Jewish General Hospital, Montreal, QC, Canada

Background: Immune checkpoint inhibitor (ICI) related hepatitis is a clinically significant immune-related adverse event (irAE) and a common cause of treatment interruption. It occurs in roughly 5 to 10 percent of patients receiving anti PD-(L)1 monotherapy and in up to one third of those treated with combination ICI therapy. Despite increasing clinical recognition, the molecular mechanisms and predictive factors underlying ICI hepatitis remain poorly defined. The Montreal Immune-Related Adverse Events (MIRAE)-led hepatitis project aims to characterize the immune cell populations and underlying transcriptional programs associated with ICI-hepatitis pathogenesis. **Methods:** This translational study is conducted within the MIRAE biobank, a prospective multicenter cohort of ICI-treated patients with and without irAEs. The hepatitis cohort includes patients with longitudinal plasma samples collected at baseline, on treatment, and at irAE onset. Ongoing immune profiling efforts include plasma-based cytokine and chemokine analysis, high-throughput plasma proteomics, and single cell RNA sequencing of PBMCs. Preliminary analysis focused on plasma proteomics. Five patients with high-grade ICI-hepatitis and five ICI-treated controls without irAEs were selected and matched by age, sex, and primary tumor. Plasma samples were analyzed using the SomaScan 11K assay to identify differentially expressed proteins and enriched immune pathways. **Results:** ICI-related hepatitis was clinically severe, requiring systemic corticosteroids in all cases and additional immunosuppressive therapies in most patients. ICI-hepatitis cases showed significantly higher plasma levels of liver injury markers, including ALT and AST, compared with matched controls. Widespread alterations were observed in the circulating proteome, with strong upregulation of liver-enriched proteins and inflammatory mediators. Gene set enrichment analyses revealed enrichment of liver-associated pathways including xenobiotic and bile acid metabolism, as well as IL-12 signaling, interferon-α and γ, neutrophil-associated pathways, and liver-resident macrophage signatures. Pathway analysis of single cell data revealed enhanced cytotoxic activity of CD8 T cells during ICI hepatitis, as exemplified by upregulation of the CTL and IL-6 pathways. **Conclusions:** ICI-hepatitis was associated with circulating immune signature characterized by liver injury markers, inflammatory mediators, and enrichment of innate immune pathways. These findings provide molecular insight into the immunopathogenesis of ICI hepatitis and inform future biomarker discovery, druggable pathways, and risk stratification. Research Sponsor: None.

Association of neutrophil percentage-to-albumin ratio with progression-free survival and overall survival in cancer patients treated with PD-1/PD-L1 inhibitors. First Author: Wenhui Liu, The Second Xiangya Hospital of Central South University, Changsha, Hunan, China

Background: The Neutrophil Percentage-to-Albumin Ratio (NPAR) reflects systemic inflammation and nutritional status. Its prognostic and predictive value in cancer patients treated with PD-1/PD-L1 inhibitors remains unclear. We investigated the association of the baseline of NPAR with PFS and OS in cancer patients who received PD-1/PD-L1 inhibitors. **Methods:** A retrospective cohort of 532 patients treated with PD-1/PD-L1 inhibitors at the Second Xiangya Hospital of Central South University between 2018 and 2024 was enrolled. Participants were divided into tertiles based on the baseline of NPAR. PFS and OS were assessed using Kaplan–Meier method and log-rank tests. Univariable and multivariable Cox proportional hazards models were employed to examine the association between NPAR and survival outcomes, with sequential adjustment for clinically relevant confounders. **Results:** The median PFS and OS of total patients was 21.3 months (IQR, 10.5–32.7) and 24.7 months (IQR, 16.9–41.5), respectively. Individuals with elevated NPAR experienced significantly worse PFS and OS than those with low NPAR and medium NPAR (PFS: $p < 0.05$; OS: $p < 0.0001$). Subgroup analyses showed the consistent results in the lung cancer patients (PFS: $p < 0.05$; OS: $p < 0.01$). In univariate COX regression analyses, each one-unit increment in NPAR corresponded to hazard ratios (HRs) of 1.032 (95% CI, 1.004–1.062; $p < 0.05$) for PFS and 1.069 (95% CI, 1.035–1.104; $p < 0.001$) for OS. Multivariate Cox regression analysis identified that a high NPAR level remained independently associated with inferior survival outcomes after adjusting for confounders. Compared with the low NPAR group, the high NPAR group showed worse PFS (HR, 1.38; 95% CI, 1.03-1.84; $p < 0.05$) and OS (HR, 1.95; 95% CI, 1.36-2.79; $p < 0.001$) in the fully adjusted model (Model 4). **Conclusions:** Elevated NPAR can independently predict worse PFS and OS in cancer patients receiving PD-1/PD-L1 inhibitors and represents a simple, low-cost biomarker for clinical risk stratification. Research Sponsor: None.

Plasma-TMB (pTMB) and circulating tumor fraction (ctF) dynamics as biomarkers of benefit from the addition of atezolizumab to first-line FOLFOXIRI/bevacizumab in metastatic colorectal cancer (mCRC): A translational analysis of the AtezoTRIBE study. First Author: Veronica Conca, Unit of Medical Oncology 2, Azienda Ospedaliera Universitaria Pisana and Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy

Background: TMB-high pMMR mCRC patients (pts) do not seem to derive benefit from immune checkpoint inhibitors (ICIs). In the CO.26 trial, pMMR/MSS mCRC pts with high baseline pTMB had better outcome with ICIs than those with low pTMB. Moreover, in the AtezoTRIBE study, tissue TMB was identified as a promising biomarker able to identify a subgroup with potential benefit from the addition of atezolizumab to first-line FOLFOXIRI/bev. In that trial, the addition of atezolizumab did not improve ORR, and PFS curves separated only after approximately 6 months. Given this delayed treatment effect observed, we hypothesized that dynamic liquid biopsy biomarkers could identify early molecular changes associated with subsequent immune-sensitivity. Here we evaluated the prognostic and predictive role of both pTMB and on-treatment ctF dynamics in the AtezoTRIBE trial. **Methods:** Pts with untreated mCRC enrolled in the AtezoTRIBE trial (NCT03721653) and with available plasma at baseline (T0) and at the end of induction (T1) were included. Samples were analyzed using the Tempus xF assay, a 105-gene cell-free liquid biopsy panel, to determine ctF by Tempus xFv2 cTF algorithm, and pTMB. pTMB was assessed as a dichotomous variable (high: ≥26 mut/Mb). ctF dynamics between T0 and T1 identified molecular responders (MRs), i.e. pts with the top 30% relative ctF reduction including clearance below quantification/detection limits at T1, and non responders (nMRs). Cox models stratified by liver metastases, and including treatment-by-biomarker interaction when appropriate, were used for PFS analyses (likelihood ratio test, p<0.15). **Results:** pTMB was evaluable in 123/155 (79%) T0 samples, and 20 (16%) were classified as pTMB-high. Baseline characteristics were balanced between pTMB-high and pTMB-low groups. High pTMB was associated with longer PFS (HR: 0.69 [90%CI 0.43-1.10], p=0.095), while no interaction between pTMB and treatment arm was observed (p_{int}=0.871). Among 89 pts with evaluable ctF at T0 and T1, 63 (71%) were MRs. Baseline clinical and molecular characteristics did not differ in the MR and nMR groups. A significant interaction (p=0.132) between ctF dynamics and MR was reported, with nMRs achieving higher benefit from the addition of atezolizumab to FOLFOXIRI/bev (HR: 0.33 [90%CI: 0.16-0.69]) than MRs (HR: 0.76 [90%CI: 0.03- 3.95). A sensitivity analysis including 6 additional pts with undetectable ctF both at T0 and T1 provided consistent findings (p_{int}=0.108). **Conclusions:** The addition of ICI to first-line chemotherapy may be more efficacious among mCRC pts with lower molecular response to the upfront induction regimen, as measured by ctF dynamics. If independently validated, ctF molecular response biomarker might be useful for future trials' design. Research Sponsor: Tempus; GONO Foundation.

A phase 2, open-label, multi-center, single-arm study of atezolizumab and bevacizumab in the treatment of second line and beyond, recurrent/metastatic endometrial cancer. First Author: Katherine Cynthia Fuh, University of California, San Francisco, San Francisco, CA

Background: The treatment paradigm for advanced/recurrent endometrial cancer (EC) is undergoing rapid transformation. Currently, use of immune checkpoint inhibitors (ICI) is standard of care for deficient mismatch repair (dMMR) tumors in the front line setting and ICI "can" be used in proficient MMR (pMMR). The purpose for this study is to evaluate an alternative ICI and anti-angiogenic regimen, atezolizumab plus bevacizumab in pts with recurrent EC with no prior ICI use and to identify blood-based correlates of non-responders early in treatment. **Methods:** This multicenter, single-arm, open label phase 2 trial (NCT03526432) enrolled pts with recurrent EC who had relapsed following platinum based chemotherapy. No prior ICI was allowed. Treatment consisted of atezolizumab 1,200 mg plus bevacizumab 15 mg/kg iv on day 1 every 21 days until progression or toxicity. The primary endpoint was objective response rate (ORR). Peripheral whole blood was collected at baseline and after 2 cycles of therapy, and high-dimensional immune profiling was performed. **Results:** Sixty-five pts were enrolled and received at least one dose of trial treatment. Fifty-six pts were response-evaluable (45 with pMMR tumors, 7 with dMMR tumors and 4 with unknown MMR status). Median age was 65 years. All pts had received at least one prior chemotherapy and 22 pts (39.3%) received prior radiation therapy. The ORR was 33.9%; 95% CI, 21.8 to 47.8; (19/56 patients), which include 5 complete and 14 partial responses; median duration of response (DOR) was 16 months. In addition, 63% of pts survived progression-free for at least 6 months. The median PFS was 8.8 months (95% CI, 5.5 to 12.0). The median OS was 41.55 months (95% CI, 27.0 – 57.5). The most common grade 3 or 4 adverse events were hypertension (21.5%), fatigue (7.7%) and diarrhea (7.7%). In peripheral blood analysis, non-responders demonstrated expansion of a suppressive myeloid population characterized by PD-L1^{+}CD16+ monocytes. There was an increase of ICOS^{+} Tregs consistent with an immunosuppressive phenotype. Within the effector T cell compartment, central memory CD8^{+} T cells expressing Fas and CD27 expanded in non-responders. **Conclusions:** The combination of atezolizumab and bevacizumab in patients with recurrent EC and post cytotoxic chemotherapy has efficacy in both dMMR and pMMR populations and a toxicity profile that appears more favorable than other treatments. This data suggests atezolizumab and bevacizumab could be considered as an alternative regimen in the recurrent, metastatic setting among pts who are ICI naïve and for whom there are concerns regarding the adverse events of treatment. Peripheral whole blood analysis of non-responders correlated with immune angiogenic escape mechanism with higher levels of ICOS+Tregs, Fas+CD27+ CD8T cells, and PDL1+ CD16+ monocytes. Clinical trial information: NCT3526432. Research Sponsor: Genentech.

Analysis of circulating small extracellular vesicle-associated miRNA in head and neck squamous cell carcinoma (HNSCC): Biomarker discovery in pre-operative neoadjuvant nivolumab. First Author: Joseph Patrick Flemming, Department of Medicine, Jefferson Abington Hospital, Abington, PA

Background: Standard treatment options for HNSCC include chemotherapy, radiation, surgery, and immunotherapy. Immune Checkpoint Inhibitors (ICI) are safe and improve survival in platinum-refractory and metastatic HNSCCs. Further studies are needed to efficiently stratify patients who may benefit from ICIs. MYC-V1 is a family of oncogenes, induced by MYC signaling, that is negatively correlated with response to ICI in HPV+ HNSCC. Non-invasive Biomarkers (NiBs) identifying patients with low MYC-V1 expression may aid in predicting response to ICIs. Small extracellular vesicles (sEVs) are membrane-bound mediators of intercell communication that are present in circulation, serving as a promising source of NiBs. The Let-7 family of tumor suppressors are negative regulators of the MYC-V1 gene family and exhibit low expression in HNSCC compared to healthy controls. Let-7 family members, such as Let-7d and Let-7c, may play a role in ICI responsiveness via PD-L1 and MYC mRNA degradation, respectively. Here, we analyze the miRNA profile of sEVs from patients enrolled in a randomized Phase I clinical trial undergoing Neoadjuvant Nivolumab therapy. (NCT03238365). **Methods:** Plasma was collected before and after treatment (N=24) with ICI. 12 patients were included and stratified based on HPV status (6 HPV-, 6 HPV+) and pathologic treatment response (pTR) (6 Responders [R], 6 Non-responders [NR]). pTR >20% of tumor surface area as graded by two pathologists was R; 0% was NR. sEVs were isolated via immunoprecipitation targeting tetraspanins CD63/9/81. miRNA was isolated and NGS was performed. Analysis was performed using Python and Biomni. Log2FC (FC) compared expression levels between groups and a False Discovery Rate (FDR) <.05 was significant. **Results:** 189 miRNAs were detected in HNSCC sEVs. Analysis comparing HPV+ R vs NR revealed 48 miRNAs with significantly different levels between these pretreatment groups. 47 were more abundant in R; 1 was less abundant. miRNAs found at higher levels in HPV+ R include the Let-7 family. Let-7d was most abundant (FC: 2.26, FDR 0.04), with a family (Let-7a,b,d,f,g,i) FC range of 1.63-2.26 (FDR 0.03-0.05). Following treatment with ICI, HPV+ patients had increased Let-7c levels (FC 4.71, FDR 0.02) compared to pretreatment. Analysis of HPV– R vs NR showed 0 miRNA that met statistical significance. **Conclusions:** Here, we show that ICI-responsive HPV+ HNSCC is associated with high levels of circulating, sEV-contained Let-7 family members and that Let-7c is increased in response to ICI in those same patients. We propose that a MYC-V1-suppresive, PD-L1-destabilizing mechanism may be present in patients with higher than average Let-7 expression, conferring sensitivity to ICI, and that sEV-associated Let-7 levels may serve as NiBs to identify these patients as favorable ICI candidates prior to treatment. T-cell stem-like memory cells as a novel biomarker to identify patients with sustained disease control during treatment with PD-(L)1 immunotherapy. First Author: Victor Joo, CHUV, Lausanne, Switzerland

Background: Reliable, clinically easily testable biomarkers to monitor the benefit of treatment with immune checkpoint inhibitors (ICI) remain limited. We performed comprehensive analysis of markers defining differentiation and functional status of different populations of peripheral blood T-cell in order to identify biomarkers associates to treatment response in treated patients. **Methods:** Peripheral blood was analyzed from metastatic patients receiving PD-(L)1–based therapy: anti–PD-(L)1 monotherapy (n=102), combination therapies (n=35), or chemo-immunotherapy (n=14). Sampling time on therapy was heterogeneous, recorded, and included in sensitivity analyses. All patients provided informed consent under IRB approval. A variety of CD4 andCD8 cell populations (naive, stem-like memory [SCM], central memory [CM], effector memory [EM], EMRA/TEMRA). were analyzed using -standardized multiparameter flow cytometry. Pre-specified stem-like–to–effector balance ratios were computed within CD4 and CD8 (SCM/CM and SCM/EM; SCM/EMRA exploratory). Markers analysis included CD45RA, CCR7, CD95, TCF1/TCF7, TOX, TIGIT, and Ki-67). Clinical benefit was assessed by disease control rate (DCR=CR+PR+SD) versus progressive disease (PD). Biomarkers were analyzed using Mann–Whitney U tests and clustered using unsupervised 1D k-means. Time-to-event analyses used univariable Cox models for time to disease control loss (DCL), defined from ICI initiation to first PD (or discontinuation for progression). **Results:** Among 151 patients, DCR n=89 and PD n=62, disease control was characterized by a stem-like/early memory blood T-cell profile. DCR showed higher CD4 and CD8 naive and SCM frequencies ($p<0.05$), whereas PD showed enrichment in differentiated T cell populations including CD4 CM/EM and CD8 EM ($p\leq0.01$ to $p<0.0001$). Stem-like–to–effector cell ratios were higher in DCR for both CD4 and CD8 (SCM/CM $p<0.001$; SCM/EM $p<0.01$) and for CD4 SCM/EMRA ($p<0.05$). In total CD3 T cells, DCR had higher CD45RA ($p<0.001$), CCR7 ($p<0.05$), and TCF1/TCF7 ($p<0.05$), with lower CD95 ($p<0.05$) and reduced TIGIT ($p<0.01$), TOX ($p<0.05$), and Ki-67 ($p<0.05$). In Cox models for DCL (inverse-coded; HR>1 favorable), significant associations were observed across subsets, ratio, and marker features (HR range 1.7–4.8; all $p<0.05$), with the strongest effects for stem-like–to–effector cell ratios and differentiated subset metrics. Associations were observed across PD-(L)1–based regimens. **Conclusions:** Stem-like memory CD4 and CD8 T cells represent a new marker associated with efficacious response to ICI and DCR while a dominant effector/terminal differentiation profile to DCL and PD. These findings underscore the importance of immune monitoring to identify patients at risk of early loss of treatment benefit and disease progression and to guide treatment modifications. Real-world concordance of tumor mutational burden (TMB) between blood (circulating tumor DNA) and tissue, and its association with immunotherapy response. First Author: Kyle VanDommelen, Cleveland Clinic, Cleveland, OH

Background: Tissue-derived tumor mutation burden (tTMB) ≥10 mutations/Mb is a histology-agnostic predictive biomarker for the immune checkpoint inhibitor (ICI) pembrolizumab. It is unknown if circulating tumor DNA–derived TMB (bTMB) is also predictive and current ASCO guidelines recommend against using bTMB alone. Concordance between tTMB and bTMB is only moderate, with reported Pearson correlation coefficients between 0.54-0.70. In prior studies, bTMB was a median 2.4-fold greater than tTMB in matched samples. This study evaluated the correlation and predictive accuracy of immunotherapy response of bTMB vs. tTMB in solid tumors. **Methods:** 221 patients with solid tumors were included from the Cleveland Clinic genomics repository who had at least one tTMB and one bTMB result between July 1, 2021, and July 1, 2025. High TMB was defined as tTMB ≥10 mutations/Mb. For bTMB, thresholds of ≥10 and ≥16 mutations/Mb were evaluated, as prior studies suggest a bTMB threshold of 16 for Guardant 360 may be comparable to a tTMB of 10. Correlation between bTMB and tTMB was assessed using Pearson's correlation coefficient. Among patients treated with ICIs, treatment response and time to treatment failure (TTF) were analyzed using both bTMB thresholds and compared with tTMB. **Results:** Among the 221 patients included in the analysis, 80 received ICIs. Median bTMB was 2.3-fold higher than matched tTMB. A strong positive linear correlation was observed between bTMB and tTMB both among patients who received ICIs ($R^2 = 0.845$, $p < 0.001$) and across the full cohort of 221 patients ($R^2 = 0.818$, $p < 0.001$). High tTMB was associated with numerically longer TTF in those with both low bTMB (median 21.3 months) and high bTMB (median 15.2 months), as shown in Table 1. Those with high tTMB/low bTMB had numerically longer median TTF compared to those with low tTMB/high bTMB (21.3 vs. 7.0 months). Increasing the bTMB threshold from 10 to 16 was associated with improved median TTF from 3.5 to 7.0 months among patients with low tTMB. **Conclusions:** This study confirms that bTMB values are consistently higher than tTMB and demonstrates a strong positive correlation between the two measures. Raising the bTMB threshold appears to improve prediction of immunotherapy response in patients with low tTMB. However, tTMB continued to show evidence of predictive value for response to ICIs regardless of bTMB, although these subgroup analyses were limited by small sample sizes. Larger, disease-specific studies are needed to better define the independent clinical utility of bTMB. Research Sponsor: None.

Time to treatment failure in TMB-high vs. TMB-low patient pairs.

	bTMB -10=H Median TTF (months)		bTMB -16=H Median TTF (months)

Functional binding of PD-1 ligands: Overcoming PD-L1 staining limitations to predict therapy response. First Author: Bar Kaufman, Ben-Gurion University of the Negev, Beer Sheva, Israel

Background: Immune-checkpoint blockade (ICB) targeting the PD-1/PD-L1 axis has improved outcomes across multiple malignancies, yet response prediction remains unreliable due to fundamental limitations of PD-L1 immunohistochemistry (IHC). As a static expression assay, PD-L1 IHC does not capture functional ligand engagement, does not account for PD-L2 contributions to PD-1 signaling, and is confounded by N-glycosylation that masks epitopes and distorts measurable abundance. These mechanistic gaps undermine biomarker accuracy and impede appropriate patient selection. To overcome these limitations, we established IcAR-PD1, a functional reporter system designed to quantify the true biological availability of PD-L1 and PD-L2 for therapeutic blockade by anti-PD-1/PD-L1 ICBs. **Methods:** We conducted a double-blinded retrospective study spanning multiple tumor types. IcAR-PD1 scores from patient-derived samples were correlated with clinical outcomes to anti-PD1 therapy and benchmarked against PD-L1 IHC, evaluating predictive accuracy, response probability, and duration-of-response. To define how PD-L1 N-glycosylation modulates inhibitory signaling and drug susceptibility, IcAR-PD1 was combined with a full four-site glycosylation mutation array and validated using primary $CD8^+$ T-cell cytotoxicity assays. **Results:** IcAR-PD1 demonstrated markedly superior predictive power compared with PD-L1 IHC, achieving AUCs of 0.87–0.92 versus 0.55–0.62. High IcAR-PD1 scores aligned with >90% response probability and >3-fold longer median duration-of-response ($p<0.01$). Incorporation of PD-L2 activity and direct measurement of functional ligand availability explained the improved performance across tumor types. Glycosylation analysis showed that fully glycosylated PD-L1 reduced blockade efficiency, with anti-PD1 treatments markedly more sensitive to glycan status than anti-PDL1. Loss of the N35 site diminished anti-PD1 efficacy by increasing release of functional soluble PD-L1, partially affecting anti-PDL1 activity. The non-glycosylated Nx4 variant displayed enhanced susceptibility to both therapies, with a disproportionately greater improvement for anti-PD1 blockade. **Conclusions:** IcAR-PD1 resolves the major limitations of PD-L1 IHC by quantifying functional ligand activity, incorporating PD-L2 contribution, and revealing glycosylation-driven resistance mechanisms. These findings support IcAR-PD1 as a precise, mechanism-based biomarker for selecting patients most likely to benefit from anti-PD1 therapy. Research Sponsor: None.

Spatial immune profiling to identify GPNMB as a mediator of immune suppression that limits response to PD-1 blockade in TNBC. First Author: Anna-Maria Lazaratos, Rosalind & Morris Goodman Cancer Institute, McGill University, Montreal, QC, Canada

Background: Breast cancer (BC) is the leading cause of female cancer-related deaths. Triple-negative BC (TNBC), accounting for ~25% of BC-related deaths, carries the poorest prognosis due to limited targeted therapies and the significant, yet still modest overall, benefit achieved with immune checkpoint blockade (ICB). Identifying drivers of immune evasion is essential to expand patient benefit from ICB. Glycoprotein-NMB (GPNMB) is highly expressed in TNBC and associated with immune suppression, metastasis, and poor clinical outcomes. However, its role in shaping the TNBC immune landscape and contributing to ICB resistance remains unclear. We investigated the impact of tumor-derived GPNMB on the tumor immune microenvironment and whether its inhibition enhances ICB efficacy. **Methods:** Imaging mass cytometry, a high-dimensional spatial proteomics platform enabling simultaneous single-cell and spatial analysis of intact tissue, was used to map the immune landscape of GPNMB-proficient and -deficient EO771 tumors. Therapeutic relevance was evaluated by combining GPNMB loss with anti-PD-1 treatment. Associations between tumor GPNMB expression, immune infiltration, and clinical outcomes were evaluated in human TNBC tumors. **Results:** GPNMB loss in mammary tumor cells significantly impaired tumor growth in syngeneic, but not athymic (T cell-deficient) mice, suggesting a T cell-dependent mechanism. $GPNMB^{KO}$ tumors showed increased immune infiltration, notably $GZMB^+/PD\text{-}1^+CD8^+$ T cells, and enhanced formation of stimulatory $CD8^+$ T cell/$CD4^+$ T cell/$CD86^+$macrophage immune triads. GPNMB loss impaired tumor engraftment in an adoptive OT-1 T cell transfer model and significantly improved response to anti-PD-1 therapy in two independent TNBC models, reducing breast tumor growth and lung metastasis. Therapeutic benefit was accompanied by increased intratumoral T cell infiltration and functional reinvigoration, reflected by increased $GZMB^+CD8^+$ T cells. In human TNBC, high tumor GPNMB expression was associated with reduced intratumoral T cell infiltration and poorer clinical outcomes. $GPNMB^{high}$ tumors exhibited reduced infiltration of $CD8^+$, $GZMB^+CD8^+$, and $CD4^+$ T cells and were enriched in immune-desert and margin-restricted phenotypes. In contrast, $GPNMB^{low}$ tumors showed increased $CD8^+$ T cell/$CD4^+$ T cell/macrophage triads, indicating enhanced immune activation. Together, these data show that elevated GPNMB expression in human TNBC is associated with T cell exclusion, and an immune-excluded tumor architecture. **Conclusions:** Our findings identify tumor-derived GPNMB as a clinically relevant mediator of T cell exclusion and suppression in TNBC. Therapeutic targeting of GPNMB in combination with PD-1 blockade may enhance the efficacy of ICB and expand the subset of TNBC patients who derive meaningful clinical benefit, ultimately improving clinical outcomes. Age-associated genomic instability and inflammatory pathway activation: A pan-cancer multi-omics analysis of the TITANIA framework. First Author: Shugo Yajima, National Cancer Center Hospital East, Kashiwa, Japan

Background: Aging is associated with increased cancer incidence and altered tumor biology, yet molecular mechanisms underlying age-related differences remain poorly characterized at the multi-omics level. We hypothesized that elderly patients may exhibit coordinated increases in genomic instability and inflammatory pathway activation. **Methods:** We performed integrated multi-omics analysis comprising whole genome sequencing, RNA sequencing, and data-independent acquisition mass spectrometry-based proteomics on 153 treatment-naive patients across six cancer types (colorectal cancer n=52, gastric n=19, kidney n=32, non-small cell lung cancer n=27, ovarian n=19, liver n=4). The TITANIA study provided matched tumor and normal tissue specimens with standardized collection protocols (median cold ischemia time: 12 minutes). Patients were stratified by age ($\leq$60 years, n=40; $>$60 years, n=113). Inflammation scores were calculated using ssGSEA of six Hallmark inflammatory pathways. Tumor microenvironment subtypes were identified using xCell deconvolution followed by k-means clustering (k=3). **Results:** Tumor mutation burden (TMB) showed a significant positive correlation with age (Spearman ρ=0.334, P$<$0.001), with elderly patients demonstrating higher median TMB than younger patients (4.55 vs 2.84 mut/Mb, P$<$0.001). Inflammation scores showed positive correlations with age in tumor tissues at both RNA (ρ=0.223, P=0.01) and protein (ρ=0.233, P=0.005) levels. Normal tissue inflammation correlated with paired tumor TMB (RNA: ρ=0.283, P=0.027; Protein: ρ=0.387, P$<$0.001), raising the possibility that systemic inflammaging may be associated with tumor genomic instability. TME clustering identified three subtypes: Immune-Hot (n=14), Immune-Cold (n=92), and Vascular-Rich (n=30). Notably, all patients in the Immune-Hot cluster were elderly ($>$60 years). TMB positively correlated with B cells, neutrophils, and M1 macrophages, while negatively correlated with stromal score and endothelial cells. The EPITHELIAL_MESENCHYMAL_TRANSITION pathway showed potential as a prognostic marker at both omics levels (C-index: RNA 0.63, Protein 0.61), though further validation is warranted. **Conclusions:** This pan-cancer multi-omics analysis demonstrates age-dependent genomic instability coupled with inflammatory pathway activation in both tumor and normal tissues, consistent with the inflammaging hypothesis. The novel finding that normal tissue inflammation correlates with tumor TMB suggests systemic inflammaging may contribute to tumor evolution, with potential implications for age-adapted immunotherapy strategies. A new HLA genotyping algorithm to show accuracy and concordance between tumor and normal samples. First Author: Ariane Lozac'hmeur, Tempus AI, Inc., Chicago, IL

Background: HLA genotyping, specifically HLA-A*02:01 is an actionable marker in uveal melanoma for Tebentafusp, a bispecific gp100 peptide-HLA-directed CD3 T cell engager, with ongoing clinical trials investigating its use in HLA-A*02:01 positive cutaneous and mucosal melanoma. However, prior work has shown a discrepancy in this marker between blood and somatic tumor testing (Seedor R et al ASCO 2023). Given therapeutic implications of these discordances, a better understanding of tumor versus normal HLA testing concordance is critical. **Methods:** The Tempus HLA genotyping algorithm was run on a cohort of 191 patients, each with a tumor and a normal sample. The reference HLA genotype was determined by an independent lab using the GenDx HLA genotyping kit and long read sequencing of the normal sample. Samples that failed sequencing in either lab were excluded from the analysis. Concordance between tumor and normal samples was additionally evaluated on a cohort of 7,821 solid-tumor samples from a variety of sites, selected from the Tempus multimodal database. **Results:** The Tempus HLA genotyping algorithm is highly accurate ($>$98.9% on all HLA genes except DQA1). Specifically, it has an accuracy of 100% on the HLA-A gene, using either the tumor or normal sample. On the larger tumor/normal comparison cohort (7,821 samples), the Tempus HLA genotyping algorithm is highly concordant ($>$99% for all genes except HLA-DQA1 [94.3%]). For the 183 melanoma samples in this cohort, concordance was similar with 100% for HLA-A and HLA-B and 99.5% (182/183) for HLA-C, further confirming that HLA genotyping can be performed accurately on melanoma tumor samples. Investigation of all discordances on HLA genes for which HLA LOH results were available (HLA-A, -B and -C) shows that 84% (88/105) of those discordant samples have somatically lost the allele responsible for the discordance. Of LOH positive discordant samples, 73% (64/88) had a tumor purity $\geq$70%. Thus, over half (64/105) of the discordances between tumor- and normal-HLA genotyping are caused by high tumor purity HLA LOH positive samples. On samples meeting these criteria, concordance drops to 86%-89%. **Conclusions:** The Tempus HLA genotyping algorithm is an extremely accurate laboratory developed test that provides accurate results, regardless of whether the normal or tumor sample is used. Concordance between normal- and tumor-based results is above 99.5% in a large-scale dataset, provided the sample does not have HLA LOH and a tumor purity over 70%. These findings suggest that this test can rapidly screen patients for HLA genotype and match them to appropriate clinical trials but emphasize the importance of a normal sample for high tumor purity specimens. Research Sponsor: Tempus AI, Inc.

	Accuracy (normal)	N (normal)	Accuracy (tumor)	N (tumor)
HLA-A	100.0%	189	100.0%	189
HLA-B	99.5%	187	99.0%	189
HLA-C	100.0%	185	98.9%	185
HLA-DQA1	99.5%	182	97.9%	189
HLA-DQB1	100.0%	186	99.5%	187
HLA-DRB1	98.9%	182	98.9%	182

Pan-cancer analysis of STAT6 expression and its relationship with tumor microenvironment characteristics and survival. First Author: Hiba Narvel, Division of Hematology and Oncology, Medical College of Wisconsin, Milwaukee, WI

Background: Co-targetable immune pathways influence cancer outcomes and responses to immune checkpoint inhibitors (ICIs). We examined the transcriptomic expression and clinical significance of signal transducer and activator of transcription-6 (STAT6), an immune-modulatory signaling factor activated by IL-4 and IL13 and involved in innate immunity in infection and cancer. **Methods:** Transcriptomic expression across 395 genes was measured in various solid tumors from 514 patients with advanced cancer, normalized to a reference population (n=735), and reported as percentiles (high defined as $\geq$75th percentile). We evaluated association between high STAT6 expression and transcriptomic expression of STAT6-related markers (IL4, IL13, TGFB1, IL10, CD8, CCL18, TNFRSF14 [HVEM], VISTA) and currently targetable immune checkpoints (PD-1, PD-L1, PD-L2, CTLA-4, LAG3). Genomic alterations were also assessed for the association with high STAT6 expression. Variables with P$<$0.2 in univariable analysis were included in the subsequent multivariable logistic regression model incorporating genomic, immunomic, and clinical factors. Clinical outcomes were evaluated using Kaplan–Meier method and Cox regression model. **Results:** High STAT6 expression was observed in 184 patients (35.8%); 2 (0.4%) had zero measurable expression. High STAT6 was associated with TMB $<$10 muts/Mb, high expression of LAG3, PD-L2, IL13, TNFRSF14 (HVEM), and VISTA (all immunosuppressive), and a diagnosis of colorectal cancer in multivariable analysis. Breast cancer was negatively associated with high STAT6. In univariable analysis, alterations in SMAD4, KRAS, and APC were significantly associated with high STAT6, though none remained significant in the multivariable model. In advanced cancer patients, high STAT6 was associated with shorter survival (N=489 with clinical data curated, Hazard ratio 1.44, 95% confidence interval 1.03–2.02, p=0.034). Among 217 ICI-treated patients, high STAT6 did not correlate with survival. **Conclusions:** High STAT6 expression associates with a biologically coherent tumor microenvironment characterized by factors mediating profound immune suppression. The STAT6-high phenotype is mechanistically linked to an exhausted immune landscape, evidenced by the co-expression of inhibitory checkpoints LAG3 and VISTA, and may be further driven by an IL13/STAT6 autocrine loop. Clinically, high STAT6 correlates with shorter survival in patients with advanced cancers. Prospective validation of this STAT6-driven signature is warranted to guide the development of precision therapy trials aimed at co-targeting this pathway to improve outcomes. Beyond TMB: Characterizing tumor-intrinsic genomic architectures of immune resistance. First Author: Ashok K. Vaid, Medanta, The Medicity, Gurugram, India

Background: Immune checkpoint inhibitors (ICI) are increasingly selected based on tumor mutational burden (TMB); however, clinical benefit remains inconsistent. We hypothesized that tumor-intrinsic genomic alterations associated with immune suppression, immune exclusion, and antigen presentation failure frequently coexist with ICI-enabling biomarkers and define distinct resistance architectures. **Methods:** We analyzed tissue-based genomic profiling data from 7,773 solid tumors. TMB-high (TMB-H) tumors were evaluated for genomic alterations implicated in ICI resistance, including *PTEN* loss-of-function (LOF), *STK11* and *KEAP1* LOF, *WNT*/β-catenin pathway alterations (*CTNNB1* activating mutations, *APC* truncation/biallelic loss), *B2M* LOF (antigen presentation), *JAK1/2* LOF (interferon signaling), and *MDM2/MDM4* amplification. **Results:** Among 908 TMB-H tumors, 30.6% harbored at least one immune resistance–associated alteration. *PTEN* LOF was the dominant functional resistance event (7.6%) and represented the central hub in tumors with multiple resistance alterations (65.6%; 21/32). *WNT* pathway alterations were frequent, with *APC* truncation (15.9%; 144/908) exceeding *CTNNB1* mutations (2.6%; 24/908), indicating heterogeneous modes of *WNT* activation. Importantly, *WNT*-driven tumors demonstrated divergent immune escape architectures: *CTNNB1*-mutant tumors were enriched for *B2M* LOF (16.7%; 4/24), whereas *APC*-mutant tumors rarely harbored *B2M* loss (0.7%; 1/144), suggesting antigen presentation-dependent versus immune-exclusion-dominant resistance, respectively. Across the TMB-H cohort, increasing mutational burden was significantly associated with higher *B2M* LOF frequency (Wilcoxon rank-sum p = 3.6×10^{-6}), consistent with immune editing under high neoantigen pressure. Interferon signaling alterations were rare (*JAK1*: 0.2%; 2/908; *JAK2*: 0.0%; 0/908). **Conclusions:** TMB identifies immune pressure but not immune competence. Intrinsic ICI resistance in TMB high tumors is structured around a *PTEN-WNT-B2M* genomic axis, with distinct immune escape architectures determined by the mode of *WNT* activation. Integrating negative genomic predictors of immune response with established biomarkers may improve immunotherapy stratification and inform development of rational combination strategies. Research Sponsor: None.

Prevalence of genomic alterations associated with intrinsic ICI resistance in TMB-high solid tumors.

ICI resistance marker	Prevalence in TMB-High Tumors
STK11	2.4%
KEAP1	0.3%
PTEN	7.6%
CTNNB1	2.6%
APC	15.9%
B2M	2.4%
JAK1	0.2%
JAK2	0.0%
MDM2	2.5%
MDM4	0.4%

Safety, PK/PD, and efficacy results from Expand-1: A phase 1 dose escalation study of the novel PD-1 targeted IL-2R-βγ agonist sunekafusp alpha (ANV600) as a single agent and in combination with pembrolizumab in patients with advanced solid tumors. First Author: Markus Joerger, Health Ostschweiz (HOCH), St. Gallen, Switzerland

Background: Sunekafusp alpha (ANV600) is a novel PD-1-targeted, IL- 2Rβ/γ agonist, which binds, without blocking, a unique epitope distinct from pembrolizumab, or other PD-1 checkpoint inhibitors. **Methods:** In this phase 1 study, safety, tolerability, pharmacokinetics, pharmacodynamics, and preliminary efficacy of increasing doses of ANV600 administered intravenously in two different dosing regimen were investigated in patients with advanced solid tumors as monotherapy and in combination with pembrolizumab. A Bayesian Optimal Interval design guided the dose escalation to determine the MTD and RP2D. **Results:** 63 patients were treated: 44 in monotherapy at 10 to 150 μg/kg ANV600 and 19 in combination therapy at 30 to 90 μg/kg ANV600. The median (range) number of previous lines of treatment was 4 (1-16) in monotherapy and 4 (2-10) in combination therapy. In mono- and combination therapy 27 (61%) and 9 (47%) patients were previously treated with a checkpoint inhibitor (CPI). ANV600 was generally well tolerated. Most common treatment related adverse events were pyrexia, transient and self-limiting transaminase elevations, and low-grade (≤G2) cytokine release syndrome. No treatment-related death was reported. The recommended phase 2 dose of ANV600 was determined to be 90 μg/kg Q1W as starting dose for 4 weeks followed by 150 μg/kg Q2W as maintenance dose. Selective targeting of PD-1-expressing cells was demonstrated, with preferential induction of proliferation of PD-1^{+} CD8^{+} T cells compared to PD-1^{-} CD8^{+} T cells. In the monotherapy setting, 12 patients (32%) experienced target lesion shrinkage; 4 of these (33%) were CPI treatment-naïve. Disease control was observed in 16 patients (42%). Clinical benefit was in general long lasting. A complete response was confirmed in 1 patient with bronchial adenocarcinoma, starting at 6 months after initiation of monotherapy treatment and still ongoing after 9 months of treatment. The patient was previously progressing under 1st line anti-PD-L1 therapy and 2nd line chemotherapy with carboplatin and paclitaxel. Similarly, in the combination therapy setting, 4 patients (24%) experienced target lesion shrinkage; 2 of these (50%) were CPI treatment-naïve. Disease control was observed in 10 patients (59%). **Conclusions:** ANV600 as monotherapy and in combination with pembrolizumab showed a favorable safety profile. Highly promising efficacy signals with one ongoing complete response, several long-lasting partial responses and stable diseases were reported in CPI-naïve and CPI pre-treated patients, including CPI-resistant tumors. Clinical trial information: NCT06470763. Research Sponsor: Anaveon AG.

Multi-omics analysis from the IMMUcan consortium to identify predictors of chemo-immunotherapy response in early-stage triple-negative breast cancer. First Author: Andrea Joaquin Garcia, Institut Jules Bordet, Université Libre de Bruxelles, Bruxelles, Belgium

Background: Combining PD-1/PD-L1 immune checkpoint blockade (IO) with neoadjuvant chemotherapy (CT) is now a standard treatment for early-stage triple-negative breast cancer (eTNBC). However, no validated biomarker is currently used to guide patient selection for CT-IO benefit. We aimed to define baseline tumor–immune–stroma ecosystem states that explain differential responses and could inform future biomarker-driven trial designs. **Methods:** The IMMUcan consortium prospectively enrolled 422 patients with eTNBC treated with CT alone (n=221) or CT-IO (n=201). Pretreatment FFPE biopsies underwent whole-exome sequencing (n=397), RNA sequencing (n=360), multiplex immunofluorescence (2 panels, n=353/368), and imaging mass cytometry (n=341). Response was assessed as pathological complete response (pCR) versus residual disease (n=400). Clinical, genomic, transcriptomic, and spatial features were analyzed for associations with pCR and treatment interaction. Multi-omics integration was performed using Multi-Omics Factor Analysis (MOFA) to derive latent factors and ecosystem states. **Results:** Baseline clinicopathological characteristics were balanced between groups, while the pCR rate was higher with CT-IO than CT alone (73.1% vs 54.8%; Δ=20.4%; $p<0.01$). High tumor grade and tumor-infiltrating lymphocytes predicted pCR in both groups without IO-specific predictive value. Among transcriptomic TNBC subtypes, immunomodulatory, mesenchymal (M), and luminal androgen-receptor (LAR) derived the greatest benefit from CT-IO. Spatial profiling identified as key CT-IO responsive feature the enrichment of activated PD-1^{+}GZMB^{+}CD8^{+} T cells in proximity to tumor cells. MOFA identified biological axes with predictive value, including organized adaptive immunity, effector functions, immune-memory, stromal/angiogenic barrier, and luminal-metabolic lineage. Organized adaptive immunity predicts CT-IO benefit in M and LAR subtypes (OR: 5.42; 95% CI 0.87-33.6; p interaction = 0.048; and OR: 2.97; 95% CI 0.98-8.9; p interaction = 0.036, respectively). Conversely, LAR tumors characterized by luminal–metabolic lineage showed no benefit from CT-IO. **Conclusions:** Integration of multi-omics data revealed distinct baseline biological ecosystem states capable of identifying patients most likely to benefit from, or exhibit resistance to, CT-IO. These findings provide a comprehensive framework for designing biomarker-driven therapeutic strategies in next-generation neoadjuvant trials for early-stage TNBC. Chemotherapy-induced gut microbiota taxonomic deviation and its association with outcomes and toxicities in breast cancer: CANTO microbiota. First Author: Joana M. Ribeiro, Gustave Roussy and Paris-Saclay University, Villejuif, France

Background: Gut microbiota (GM) modulates immunotherapy (IT) efficacy and toxicity, but its impact on outcomes in breast cancer (BC) patients (pts) remains unclear. TOPOSCORE is a GM-derived score reflecting the ecosystem structure that classifies pts into SIG1+ or SIG2+ profiles, the latter being enriched in obligate anaerobes with immunostimulatory proprieties and associated with favorable IT outcomes. **Methods:** CANTO-Microbiota (target N=1000) is an ongoing substudy of the prospective CANTO cohort (NCT01993498). Stool samples were available from 209 pts (202 pre-treatment (Tx) and 94 post-Tx [after surgery, chemotherapy (CT) ±targeted-, and/or radiotherapy]), enrolled 2015-2024. GM was profiled by shotgun metagenomics and assessed as TOPOSCORE (SIG1+ vs. SIG2+) pre- and post-Tx. Associations of GM with invasive (iDFS), distant disease-free (DDFS), and overall survival (OS) (Kaplan–Meier and Cox regression models), and with treatment-related toxicities (multivariable logistic regression). Post-treatment analyses were landmark-based. **Results:** Median age was 46.6 years, 72% were premenopausal, 79% had stage II-III, 36% HER2+, 34% HR+/HER2-, and 30% TN, 89% received (neo)adjuvant CT, 15% IT and 33% anti-HER2-therapy. Median follow-up was 2.2 years. At baseline, 74% of pts had a SIG2+ profile. This profile was not associated with clinicopathologic features or clinical outcomes; however, SIG2+ was associated with a reduced incidence of post-treatment diarrhea and long-term neuropathy, and remained independently protective against neuropathy (OR 0.25, 95% CI 0.09–0.64; p=0.005). Paired analyses (n=87) revealed a significant shift in TOPOSCORE signatures post-treatment, resulting in an increase in SIG1+ prevalence from 28% to 47% (p=0.004), In univariable landmark Cox analyses, post-treatment SIG1+ was associated with worse iDFS (HR 5.0, 95% CI 1.1–4.2; p=0.04), DDFS (p=0.0053) and OS (p=0.04). In multivariate model adjusted for age, stage, and subtype, post-treatment SIG2+ remained independently protective for iDFS (HR 0.17, 95% CI 0.03–0.88; p=0.035). Assessing longitudinal GM trajectories, worsening patterns (SIG2+→SIG1+ in 28% and persistent SIG1+→SIG1+ in 20% of pts) were associated with an increased risk of iDFS (HR 5.25, 95% CI 1.11–24.7; p = 0.036). Post-treatment TOPOSCORE associations with outcomes were validated in two independent prospective cohorts outside France. **Conclusions:** Chemotherapy is associated with measurable shifts in GM composition that correlated with treatment-related long-term toxicity and outcomes. These findings support the evaluation of microbiota centered interventions during treatment in eBC. Research Sponsor: None.

Safety and preliminary efficacy of OH2 combined with BS006 sequential intratumoral injection in patients with advanced solid tumors: An open-label, dose-escalation phase Ib/II study. First Author: Han Wu, Department of Radiation and Medical Oncology, Zhongnan Hospital of Wuhan University, Wuhan, China

Background: The immunosuppressive ("cold") tumor microenvironment (TME) limits patient response to checkpoint inhibitors. Oncolytic viruses (OVs) can selectively replicate in tumor cells, leading to robust TME-remodeling. Reported here is the first clinical evaluation of a dual TME-modulating strategy based on an oncolytic HSV2 platform, whereby OH2, a clinically validated oncolytic HSV2 expressing GM-CSF, which enhances tumor lysis, antigen release, and dendritic cell recruitment in the TME, is co-injected with BS006, a second HSV2-based OV, which expresses a PD-L1/CD3 bispecific antibody that can redirect bystander T cells to tumor cells in the TME. **Methods:** BS008-001 is a multicenter, open-label phase Ib /II trial in heavily pre-treated patients with advanced solid tumors. Patients received biweekly sequential intratumoral injections of OH2 (fixed dose: 10^{7} $CCID_{50}$/mL) followed by BS006 (dose escalation: 10^{6}–10^{7} $CCID_{50}$/mL), with identical volumes being injected at the same lesion. The primary endpoint is safety and tolerability; secondary endpoints included efficacy outcomes assessed by RECIST 1.1/iRECIST. **Results:** As of January 5, 2026, a total of 15 patients with a mean age of 59.3 were enrolled (4 soft tissue sarcoma, 3 colorectal cancer, 2 melanoma, 2 biliary tract tumors, 2 breast cancer, 1 pancreatic cancer, and 1 liver cancer). 93.3% of the patients had a baseline ECOG score of 1. The mean maximum diameter of the target lesion at baseline was 91.3 mm. 100% of the patients had distant metastases to internal organs such as the liver and lungs. Safety: Incidence of TRAEs in the Safety Set was 53.3% (8/15) with mild grade 1-2 reactions, including fever (40.0%) and decreased lymphocyte count (20.0%). 1 patient developed Grade ≥3 TRAE (6.7%), but no DLT-causing AEs or premature withdrawal from the trial occurred. Efficacy: In the 13 patients with evaluable advanced multi-line solid tumors, ORR was 7.7% and DCR 38.5%. 1 melanoma patient achieved 1 PR after 11 treatments, with the total diameter of the target lesions significantly decreasing by 70.8% to 30.4 mm; another melanoma patient received 39 doses over a treatment duration of 18.9 months (SD), whereas 1 subject with leiomyosarcoma achieved SD and survived for 27.1 months. While the mOS of the 15 patients has not yet been reached, landmark 1-year OS is 78% (95% CI: 47%-92%), with 3 patients still on treatment. **Conclusions:** Sequential intratumoral administration of OH2 and BS006 in heavily pre-treated patients is feasible and safe and results in reasonable DCR, with some patients achieving long-term clinical benefits. This study supports the clinical relevance of an HSV2-based platform combination of 2 oncolytic viruses encoding GM-CSF and T-cell redirected bispecific antibodies to warm up the cold TME. Further clinical research of the platform is warranted. Research Sponsor: None.

2591 **Poster Session**

Association of SARS-CoV-2 vaccination with survival outcomes in patients with metastatic solid tumors treated with immune checkpoint inhibitors. First Author: Haris Sohail, Charleston Area Medical Center, Charleston, WV

Background: Patients with cancer experience disproportionately high morbidity and mortality from SARS-CoV-2 infection, and COVID-19 vaccination is recommended for all patients with cancer. Although vaccines primarily reduce infection related complications, emerging data suggest SARS-CoV-2 mRNA vaccines may also enhance antitumor immune responses and potentially synergize with immune checkpoint inhibitors (ICIs). We evaluated survival outcomes in vaccinated versus unvaccinated patients with metastatic solid tumors treated with immunotherapy. **Methods:** Data for adults with metastatic cancers for which ICIs are indicated were obtained from the TriNetX Research Network (2019–2024). Patients were classified by receipt of ≥1 SARS-CoV-2 mRNA vaccine around the time of ICI initiation (±1 year) and compared with unvaccinated patients. Those with prior systemic antineoplastic, endocrine, or immunosuppressive therapy before ICI initiation or who developed COVID-19 were excluded. Cohorts were propensity matched for demographics, cancer type, comorbidities, and laboratory values. Outcomes included overall survival at 90 days, 1 year, and 5 years using Kaplan–Meier analyses, and all-cause hospitalization and immune-related adverse events (irAEs) within 90 days. **Results:** After matching, 543 vaccinated and 543 unvaccinated patients were well balanced. Vaccination was not associated with increased irAEs, with similar rates of any irAE (19.0% vs 17.9%, p=0.64), gastrointestinal (3.87% vs 3.87%, p=1.00), dermatologic (11.8% vs 10.7%, p=0.56), and neurologic events (2.76% vs 2.39%, p=0.70); pulmonary and hepatic irAEs were rare. Hospitalization rates were comparable (24.9% vs 23.9%, p=0.72). Vaccinated patients demonstrated improved intermediate-term survival, with higher 1-year survival (73.35% vs 64.12%; HR 0.70, 95% CI 0.56–0.87, p=0.001), with trends toward benefit at 90 days (HR 0.69, p=0.053) and 5 years (HR 0.85, p=0.066). Landmark analysis from 1 to 5 years showed no significant survival difference (HR 1.15, p=0.34). Consistent 1-year survival benefits were observed in lung cancer (65.93% vs 52.56%; HR 0.63, p=0.0005) and melanoma (80.25% vs 68.65%; HR 0.56, p=0.0355). **Conclusions:** In this large propensity-matched real-world cohort of metastatic solid tumor patients receiving immune checkpoint inhibitors, COVID-19 vaccination was not associated with increased immune-related toxicity or hospitalization and was associated with significantly improved 1-year overall survival. Attenuation of the survival association in landmark analyses suggests potential time-related bias, supporting the need for further studies with precise exposure timing. Research Sponsor: None.

An exploratory, single-center, single-arm trial of R-ISV-FOLactis in situ vaccination for advanced soft tissue sarcoma. First Author: Qing Wang, The Comprehensive Cancer Centre of Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China

Background: Advanced soft tissue sarcomas (STSs) have limited treatment options and exhibit low responsiveness to immunotherapy, largely due to an immunosuppressive tumor microenvironment (TME). In situ vaccination (ISV) represents a promising strategy to convert immunologically "cold" tumors into "hot" ones. FOLactis, a food-grade probiotic Lactococcus lactis engineered to express a fusion protein of Fms-like tyrosine kinase 3 ligand (Flt3L) and OX40 ligand (OX40L), has shown antitumor immune activity in preclinical models. This study investigates the synergistic antitumor effect and safety of intratumoral FOLactis in combination with hypofractionated radiotherapy and anti-PD-1 therapy in clinical settings. **Methods:** In this investigator-initiated, single-arm trial, patients with advanced STS who had failed standard therapies received intratumoral injections of FOLactis combined with hypofractionated radiotherapy and PD-1 blockade. Primary endpoints included safety and efficacy, secondary endpoints encompassed abscopal responses and mechanistic exploration of treatment efficacy. **Results:** Between July 2022 to July 2025, 16 advanced STS patients were enrolled. The R-ISV-FOLactis regimen was well-tolerated, with grade 3 adverse events occurring in 37.5% of patients. Injected lesions showed a best objective response rate (ORR) of 56.25% and a disease control rate (DCR) of 100%. Median progression-free survival (mPFS) for all lesions was 6.3 months, while mPFS for injected lesions was not reached. Abscopal responses were observed in 56.25% of patients. Immunological analyses revealed increased frequencies of peripheral memory $CD8^+$ T cells, $PD\text{-}1^+$ $CD8^+$ T cells, and dendritic cells (DCs), alongside decreased regulatory T cells (Tregs) and tissue-resident $CD103^+CD4^+$ T cells in responders, indicating systemic immune activation. Furthermore, reshaped TME with reduced fibroblasts and increased immune cell infiltration were associated with enhanced antitumor immunity. Moreover, significant increase of $CD8^+$ T cell density in regions distal to neutrophil clusters, along with elevated 4−Cresol Sulfate levels suggesting neutrophil modulation. **Conclusions:** R-ISV-FOLactis exhibited a favorable safety profile and encouraging efficacy against both local and distant tumors. The treatment induced systemic immune activation and metabolic remodeling, supporting its further development as a novel ISV strategy for advanced STSs. Clinical trial information: ChiCTR2200060660. Research Sponsor: None.

Quality of life in cancer patients treated with anchored interleukin-12 (IL-12) immunotherapy: Results from a first-in-human phase 1 trial of tolododekin alfa (ANK-101). First Author: Jong Chul Park, Mass General Brigham, Harvard Medical School, Boston, MA

Background: Anchored immunotherapy is a novel method for retaining high concentrations of anti-tumor drugs in established tumors with limited systemic exposure. The integration of quality-of-life (QOL) assessment in a phase 1 study of anchored IL-12, tolododekin alfa (ANK-101), provided an opportunity to gather baseline QOL data, longitudinally measure patient well-being during drug exposure, identify associations between adverse events and patient well-being, and generate additional clinical benefit information. **Methods:** All patients enrolled in the phase 1 clinical trial of ANK-101 for patients with advanced/metastatic solid tumors were eligible and provided written informed consent. Patients were treated with direct intratumoral injection every 3 weeks up to 8 cycles over 6 months. QOL was measured by the validated FACT-G survey, which collects scores across a 27-item questionnaire that measures physical, family/social, emotional, and functional well-being. Subjects were asked to complete the FACT-G at baseline every 3 weeks during treatment and at end-of-treatment. QOL scores were evaluated by paired-sample t-tests to evaluate differences in QOL at various time intervals. Data cut-off was on October 21, 2025. **Results:** 39 of 40 (98%) patients completed at least two FACT-G surveys. The median age was 68 and 44% were female. Patients had a median of 5 lines of prior therapy (range 1-18). The most common cancer types included were melanoma (33%), head and neck (18%), cutaneous squamous cell carcinoma (8%), and colorectal cancer (8%). There were no dose-limiting toxicities but there were 42 grade 2 events in 13 subjects and five grade 3 events in 3 subjects (elevated liver transaminases, abdominal pain, neutropenia, stomatitis). At baseline, the median of QOL score was 80.5 (range 51-106). After two and four cycles, there was no decrease in QOL scores across any of the functional domains. For patients who developed grade 2 or 3 adverse events, there was a trend toward decreased QOL in social well-being (median 25.5 at baseline to 23 after two cycles; median change -2.0; p=0.08) and in physical well-being (median 24 at baseline to 20 after four cycles; median change -5.5; p=0.06 after four cycles). Patients who completed all 8 cycles of treatment demonstrated no change in any QOL measure (p range 0.14-0.70). **Conclusions:** ANK-101, the first anchored immunotherapy, was associated with QOL scores that were not significantly diminished in heavily pre-treated advanced cancer patients with a non-significant decrease in social and physical well-being among those who developed grade 2 or greater adverse events. Further, patients with visceral tumors had no difference in QOL compared to superficial lesions. Early implementation of QOL data is feasible in phase 1 trials and may be of use to identify drug impact on clinical and safety measures. Clinical trial information: NCT06171750. Research Sponsor: Ankyra Therapeutics.

Intratumoral dendritic cell (DC1) therapy prior to neoadjuvant chemotherapy in HER2-positive breast cancer (NATASHA trial). First Author: Hyo S. Han, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Enhancing the efficacy of neoadjuvant therapy (NAT) while minimizing treatment-related toxicity remains a critical unmet need for patients (pts) with HER2-positive (HER2+) breast cancer (BC). We previously reported intratumoral (IT) delivery of increasing doses (50 million and 100 million cells) of conventional type I dendritic cells (DC1) combined with anti-HER2 antibodies is safe and effective in altering the tumor microenvironment (TME) and inducing tumor regression in early-stage HER2+ BC. We conducted a phase II neoadjuvant clinical trial of IT DC1 (NCT05325632). **Methods:** Pts with early-stage HER2+ BC with tumor ≥ 1cm were eligible. Treatment included initial immunotherapy with IT DC1 weekly x6 (100 million) followed by paclitaxel 80 mg/m^2 IV weekly x12. Starting from day 1, pts also received trastuzumab (H) IV (8 mg/kg loading dose, then 6 mg/m^2) and pertuzumab (P) IV (840 mg loading dose, then 420 mg) every 3 weeks x 6 cycles. Core needle biopsies were obtained at baseline and at week 6 following the last DC1 injection and analyzed by multiplex immunofluorescence (mIF) to assess immune cell infiltration. At these timepoints and post-chemotherapy, radiologic response was assessed by breast MRI and blood was collected for biomarker and ctDNA analysis using a personalized, tumor-informed test (Signatera, Natera, Inc.). The primary end point of this study is pathologic complete response rate (pCR). **Results:** A total of 47 pts (24 HR+/HER2+, 23 HR-/HER2+) were enrolled between 5/2022 and 10/2025. Median age was 54 years (range 27-82). 21 pts had biopsy-proven axillary node positive disease with clinical stage I/II/III (7/30/10). All pts completed NAT, and 42 pts underwent surgery as of 1/22/2026. The pCR rates for HR+/HER2+ and HR-/HER2+ were 50% (12/24) and 89% (16/18), respectively. The most frequent toxicities related to DC1 were grade 1/2 chills, flu-like symptoms, headache, nausea, fever, and injection site reaction. IT DC1 + HP therapy was associated with a significant increase in intratumoral $CD3^+$ T cell infiltration and a decrease in tumor cells assessed by mIF. ctDNA levels were evaluable for 25 patients (13 HR+ and 12 HR-). Sixteen pts (64%) had positive ctDNA (6 HR+ and 10 HR-) at baseline and 14/16 cleared ctDNA with NAT (13/16 cleared ctDNA post- IT DC1+HP, prior to chemotherapy). At present (median post-surgery follow-up: 15.1 mos.; median follow-up from last ctDNA test: 8.7 mos.), no pts have experienced disease recurrence. **Conclusions:** IT DC1 + HP prior to neoadjuvant paclitaxel + HP in HER2+ BC pts was well tolerated with manageable toxicities. IT DC1 led to immune cell infiltration and ctDNA clearance with improved pathologic tumor response rates, particularly in HR-/HER2+ BC. Updated surgical outcomes and biomarker results (mIF, MRI and ctDNA) will be presented at the meeting. Clinical trial information: NCT05325632. Research Sponsor: None.

2595 Poster Session

First-in-human evaluation and preclinical mechanistic studies of targeted hyperthermia therapy. First Author: Carman Giacomantonio, Dalhousie University, Halifax, NS, Canada

Background: Photothermal conversion of near-infrared (NIR) light using specifically tuned, directly delivered gold nanorods produces controllable hyperthermia in tumor microenvironments. Precisely controlled, targeted hyperthermia therapy (THT) induces immunogenic cell death (ICD) and remodels the tumor microenvironment, promoting immune activation in otherwise poorly inflamed tumors. Here, we report an early clinical evaluation of THT integrated with mechanistic preclinical analyses. Preclinical studies: In B16F10 melanoma and CT26 colorectal models, controlled thermal dosing induced a 24–48 h ICD response marked by calreticulin and HSP70 exposure, chemokine and complement activation, and early T-cell receptor remodeling. Transcriptomic analyses revealed a dose-dependent transition from innate immune activation to a coordinated tissue repair program involving extracellular matrix remodeling. Lower thermal doses in the hyperthermic window decreased regulatory pathways and induced antigen presentation. Modulation of myeloid signaling limited macrophage accumulation, prevented tumor regrowth, and sustained antitumor inflammation. **Methods:** In a first-in-human, open-label, early feasibility study (NCT06894407), ten patients with stage IIIc/IIId/IV M1 cutaneous metastatic melanoma progressing on checkpoint inhibitor therapy received intratumoral gold nanorods (Sona Nanotech Inc.) followed by NIR-mediated heating on days 1 and 8. Up to four lesions per patient were treated, with intratumoral temperatures maintained at 42–48 °C for 5 minutes. Safety, feasibility, and early biological activity were assessed through adverse-event monitoring, clinical photography, and tumor biopsies obtained on days 15 and 29. **Results:** Clinical: THT was well tolerated, with no treatment-related serious adverse events observed. By day 15, 8 of 10 patients demonstrated regression in treated lesions. Histologic assessment showed complete tumor clearance in 6 patients, partial regression in 2 patients, and no response in 2 patients. **Conclusions:** THT-induced ICD progresses through temporally regulated immune states, including a reparative myeloid-associated phase that limits durability. Defined thermal-dose parameters provide a framework for rational integration of THT with macrophage-modulating and checkpoint-based immunotherapies. THT is safe, feasible, and biologically active in immunotherapy-refractory metastatic melanoma. Further clinical studies are needed to evaluate the efficacy of THT in immune-refractory cancers. Clinical trial information: NCT06894407. Research Sponsor: Sona Nanotech Inc.

2596 Poster Session

Evaluation of adnexal features and histological response to intralesional SP-002 in nodular basal cell carcinoma. First Author: Gregory Siller, Central Brisbane Dermatology, Brisbane, Australia

Background: No FDA approved nonsurgical therapies exist for primary nBCC at high-risk sites, e.g., H-zone, representing a significant unmet medical need. Recombinant IFN-alfa-2b previously achieved ~85% complete histologic clearance in superficial and nBCC, but required multiple (9-12) injections and was associated with systemic toxicity. SP-002 encodes human IFN-γ and enables sustained, localized cytokine expression with anti tumor activity, achieved with a once weekly, three dose regimen that demonstrates a superior therapeutic index. **Methods:** Two early phase clinical studies of SP-002 in nBCC were completed: a single lesion study (ASN-002-001, NCT02550678, n=16), and a combination multilesion study with 4 weeks of vismodegib (ASN-002-003, NCT04416516, n=21, 46 lesions). Pretreatment biopsies from ASN-002-001 served as discovery specimens, while pretreatment biopsies from ASN-002-003 were prospectively assessed by central review for adnexal features (AdnF; follicular or eccrine differentiation) using standardized criteria. Post-treatement excision specimens were evaluated by local histopathology laboratories for CHC per protocol-defined criteria. CHC rates were calculated by AdnF. **Results:** ASN-002-001: sporadic low frequency/risk BCC, AdnF(+) rate was 20%. CHC rates were 33% (5e10vp), 83% (1.5 and 3.0e11vp). ASN-002-003: high-frequency multilesion BCC, AdnF(+) rate was ~50%. CHC rates were 75% (1 nBCC)/52.9% (3 nBCC) (1.0e11vp) and 52.4% (3 nBCC) (1.5e11vp)-ITT. When analyzed by AdnF status, CHC rates were 97% in AdnF(-) lesions and 11.5% in AdnF(+) lesions. Baseline biopsies in non-responders demonstrated follicular/eccrine structures especially papillary mesenchymal bodies, harboring CKT15(+) stem cells (SC) and nuclear β-catenin, indicating active WNT signaling. Dual repression of programmed cell death effectors, CASP8/RIPK3, was also observed at baseline in lesions with residual disease with focal loss or widespread loss across tumor islands in β-catenin active regions. Either or both CASP8/RIPK3 were present in all complete responders at baseline and their absence may indicate risk for incomplete response to SP-002. **Conclusions:** SP-002 achieved high CHC rates at doses of 1.5e11vp/3.0e11vp and AdnF(-) lesions (most nBCC) had clearance rates comparable to surgical excision (>90%).Adnexal differentiation identifies a biologically distinct, treatment-resistant subset with WNT pathway activation, adnexal niches harboring CKT15(+) SC, and impaired IFN-γ cell death. These findings support AdnF as a predictive biomarker and position SP-002 as a promising non-surgical option for selected patients with nBCC. Clinical trial information: NCT02550678, NCT04416516. Research Sponsor: Ascend Biopharmaceuticals Ltd, Level 1 159 Dorcas Street, South Melbourne VIC 3205.

	CHC rate AdnF(-) n/N lesions (%)	CHC rate AdnF(+) n/N lesions (%)
ASN-002-001 (n=15, 15 lesions)	11/12 (91.6%)	0/3 (0%)
ASN-002-003 (n=21, 46 lesions)	23/23 (100%)	3/23 (13%)
	34/35 (97.1%)	3/26 (11.5%)

2597 Poster Session

Safety and feasibility of intratumoral injection of RP1 or RP2 oncolytic immunotherapies in visceral metastases. First Author: Caroline Robert, Gustave Roussy and Paris-Saclay University, Villejuif, France

Background: RPx is an investigational HSV-1-based oncolytic immunotherapy platform including RP1 (vusolimogene oderparepvec) and RP2. RP1 expresses GM-CSF and a fusogenic glycoprotein (GALV-GP-R$^-$); RP2 also expresses an anti–CTLA-4 antibody-like molecule. We report safety data from patients (pts) who received intratumoral (IT) injections of RP1/2 into visceral metastases (mets). **Methods:** Pts with advanced/metastatic solid tumors were enrolled into RP1/2 clinical trials (RP1: NCT03767348; RP2: NCT04336241). RP1/2 was injected into visceral tumors using CT or ultrasound guidance. The recommended needle gauges ranged from 17-27G. Pts received RP1/RP2 for up to 8 doses as monotherapy or in combination with nivolumab IV starting at cycle 2 or 4 for up to 2 years. Additional RP1/2 doses could be given if protocol-specified criteria were met. This analysis evaluated safety among pts receiving IT RP1/2 injections to visceral mets (defined as lung or liver mets). All safety data presented includes events occurring within 7 days after injection (except where noted). **Results:** As of data cutoff (RP1: 15OCT2024; RP2: 29AUG2025), there were a total of 665 RP1/2 injections into the lung (n = 125; median lung injections/pt/treatment course [c]: RP1 = 5.5 and RP2 = 8) and liver (n = 540; median liver injections/pt/c): RP1 and RP2 = 5) among 105 pts. The most common treatment-related adverse events (AEs) were pyrexia, chills, and fatigue (Table). A total of 9 pneumothorax (PTX) events occurred (within 3 days after injection) out of 125 lung injections (7.2%) in 19 pts receiving RP1/2; all cases were Grade (G) 1/2 and resolved. Only 1 pt required a chest tube for a G2 PTX event and the pt continued to receive RP1 after resolution. There were 3 bleeding events within 3 days after injection among 665 injections (0.5%) in the lung or liver in 105 pts receiving RP1/2. All bleeding events occurred in pts receiving RP2 liver injections and resolved (2/3 events resolved by the following day). **Conclusions:** RP1/2 injections into visceral mets were well tolerated, with a comparable safety profile to liver and lung biopsies performed in other clinical settings. The observed RPx safety profile supports the incorporation of IT injections into deep visceral tumors as part of cancer therapy. Clinical trial information: NCT03767348; NCT04336241. Research Sponsor: Replimune, Inc.

STING agonist JMKX000197 infusion in patients with malignant pleural effusion: Preliminary results from a prospective phase Ib study. First Author: Ning Li, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China

Background: Indwelling pleural catheter (IPC) is frequently used for symptomatic malignant pleural effusion (MPE), its therapeutic benefits remain limited. JMKX000197 is a novel small molecule stimulator of interferon genes (STING) agonist that activates STING to induce type I interferons and pro-inflammatory cytokines and may have a promising clinical prospect for the treatment of MPE. **Methods:** Eligible patients had advanced solid tumors with moderate-to-large MPE and had progressed on systemic therapy or had poorly controlled effusion. Patients were randomized assigned in a 1:1:1 ratio to receive intrapleural infusions of JMKX000197 (150 μg or 300 μg) combined with IPC or IPC alone (control) on day 1 and day 8. Here, we report safety, tolerability, preliminary efficacy, and PK/PD characteristics from the phase Ib study of JMKX000197 (NCT06740019). **Results:** As of October 15, 2025, 35 patients were enrolled (45.7% female, median age 59 years, 71.4% with lung adenocarcinoma). 2 patients withdrew from the study without receiving any treatment after randomization, thus, the safety and efficacy analysis was based on 33 patients who received treatment. Among 33 patients, 1 patient in the 300 μg group withdrew the informed consent after one dose while 32 patients (97%) completed the two-dose regimen (11 in 150 μg group [N=11], 9 in 300 μg group [N=10], and 12 in control group [N=12]). Treatment-emergent adverse events (TEAEs) occurred in 100%, 90%, and 83.3% of patients in the 150 μg, 300 μg, and control groups, respectively. Grade ≥3 TEAEs occurred in 3(27.3%), 1 (10%) and 1 (8.3%) patients in each group. 2 patients in 150 μg group and 5 patients in 300 μg group experienced grade 1–2 cytokine release syndrome (CRS), which were adverse event of special interest, all resolved with supportive care. No TEAE led to treatment discontinuation or death. Puncture-free survival (PuFS) was defined as the period from the removal of the IPC immediately after the last dose of treatment to the next therapeutic puncture and/or drainage or death, whichever occurs first. The median PuFS was 37 days, 116 days, and 56 days in the 150 μg, 300 μg, and control groups, respectively. Limited exposure of JMKX000197 in plasma was observed (>700 fold lower than that in pleural effusion). PD analysis showed significant elevation of IFN-β in both plasma and pleural effusion (higher in pleural effusion), along with increased TNF-α, IP-10, MCP-1, and IL-6. Immunophenotyping demonstrated enhanced CD8+ T-cell activation and reduced Treg cell proportions post-treatment (both in peripheral blood and pleural effusion). **Conclusions:** Intrapleural JMKX000197 exhibited a manageable safety profile and promising preliminary efficacy in MPE patients, with a better efficacy at the 300 μg dose. JMKX000197 may induce the production of pro-inflammatory cytokines and subsequently activate the tumor microenvironment. Clinical trial information: NCT06740019. Research Sponsor: Shanghai Jeyou Pharmaceutical Co., Ltd.

Clinical efficacy and safety of BM201 intra-tumoral injection and radiotherapy in advanced solid tumors: Results from the phase I/IIT study. First Author: Rutian Li, The Comprehensive Cancer Centre of Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China

Background: For vaccine design, an antigen and an adjuvant are necessary for an effective immune response. In the context of therapeutic tumor vaccination, in situ vaccination has garnered increasing attention as it enables tumors to provide antigens through radiotherapy or intra-tumoral (i.t.) delivery of immunomodulators. BM201, a selective TLR7/8 agonist uniquely designed for intratumoral (i.t.) administration, aims to effectively activate antigen-presenting cells and enhance immunogenicity through combination with radiotherapy by more effectively presenting the tumor antigens exposed to T cells. When combined with intravenous (i.v.) infusion of αPD-1 monoclonal antibody (mAb), it relieves tumor immunosuppression and exerts synergistic anti-tumor effects. **Methods:** This is an open-label, exploratory, and phase I/IIT study. Phase I portion was a dose-escalation study designed to investigate BM201 (dose range: 24-240mg, i.t. every 2 weeks) in combination with hypofractionated radiotherapy (5-8Gy, 4 fractions) (R-ISV-BM201) in patients with refractory or metastatic solid tumors. Phase IIT portion was designed to investigate BM201 (dose range: 24-240mg, i.t. every 3 weeks) in combination with hypofractionated radiotherapy (5-8Gy, 4 fractions) plus αPD-1 (200mg, i.v. every 3 weeks) (R-ISV-BM201 + αPD-1) in patients with refractory or metastatic soft tissue sarcomas. Primary objective of both 2 studies was safety and tolerability. Secondary endpoints included PK and preliminary anti-tumor activity according to RECIST 1.1 in Phase I, while anti-tumor activity according to irRECIST 1.1 in Phase IIT. **Results:** Till December 05, 2025, 29 patients had been treated with BM201 (19/29 in Phase I, 10/29 in Phase IIT). Among the 29 patients, 51.7% had been unresponsive to immunotherapy (prior αPD-1). Plasma exposure increased with dose. A sustained-release PK characteristic was observed in most patients experiencing tumor shrinkage. Abscopal effects were observed in 31.6% (6/19) and 50% (5/10) of patients in Phase I and Phase IIT, respectively. In Phase I, the objective response rate (ORR) was 5.2%, and the disease control rate (DCR) was 84.2%; while these were 10.5% and 84.2% in injected lesions. In Phase IIT, the ORR was 20%, and the DCR was 100.0%; while these were 46.1% and 92.3% in injected lesions. The median progression-free survival was 7.7 months, the median overall survival was 17.0 months, and the median duration of response in injected lesions was 5.6 months. The majority of TRAEs were grade 1-2. Grade 3-4 TRAEs mainly included lymphocytopenia, anemia, thrombocytopenia, and hypertension. No grade 5 TRAEs or dose-limiting toxicity was observed. **Conclusions:** R-ISV-BM201 has a manageable safety profile and has shown encouraging anti-tumor activity. A trigger systemic immune response would be expected when it is synergized with αPD-1 mAb. Clinical trial information: Phase I: NCT06368960; Phase IIT: ChiCTR2300077953. Research Sponsor: National Natural Science Foundation of China; Foundation for studies of Clinical Trials, Drum Tower Hospital; Science Fund for Distinguished Young Scholars of Jiangsu Province; Fundings for Clinical Trials from the Affiliated Drum Tower Hospital, Medical School of Nanjing University; Nanjing Medical Science and Technology Development Foundation; InnoBM Pharmaceutics Co. Ltd.

Hepatic arterial infusion chemotherapy combined with immunotherapy for unresectable intrahepatic cholangiocarcinoma: A single-arm, open-label, prospective clinical trial. First Author: Hongzhe Kang, The Third Affiliated Hospital of Harbin Medical University, Harbin, China

Background: In recent years, immune checkpoint inhibitors (ICIs) have demonstrated substantial clinical advances in the treatment of intrahepatic cholangiocarcinoma (ICC). However, the efficacy of first-line systemic chemotherapy remains suboptimal for patients with unresectable ICC. Hepatic arterial infusion chemotherapy (HAIC) can markedly elevate local drug exposure, enhance tumor cytotoxicity, and minimize systemic adverse effects. Whether the combination of HAIC and immunotherapy confers a clinical benefit for patients with unresectable ICC remains an urgent clinical issue to be addressed. **Methods:** This is a single-arm, open-label, prospective clinical trial designed to evaluate the efficacy and safety of HAIC combined with ICIs in the treatment of patients with unresectable ICC. The HAIC regimen consists of gemcitabine plus cisplatin (GC-HAIC), while programmed death-1 (PD-1) inhibitors are administered for immunotherapy, with either camrelizumab or sintilizumab chosen on a patient clinical characteristics basis. The trial was planned to enroll 30 participants. The primary endpoint was the objective response rate (ORR). Secondary endpoints included overall survival (OS), progression-free survival (PFS), and disease control rate (DCR). Safety was assessed through the monitoring and grading of adverse events (AEs) according to the National Cancer Institute Common Terminology Criteria for Adverse Events (NCI-CTCAE) version 5.0. **Results:** From August 2022 to January 2025, a total of 31 patients with unresectable ICC were enrolled and received the protocol-defined treatment. The ORR was 41.9% according to RECIST 1.1 criteria, while the ORR assessed per mRECIST criteria was 71%. The median follow-up time was 22.0 months (95% CI, 17.9–26.7 months). The median OS was 20.0 months (95% CI, 15.7–28.6 months), and the median PFS was 12.3 months (95% CI, 10.9–21.3 months). The DCR reached 93.5%. Treatment-related AEs of any grade occurred in 83.9% of patients, whereas grade 3 or 4 AEs were observed in only 16.1% of participants. **Conclusions:** This study evaluated the efficacy and safety of GC-HAIC combined with anti-PD-1 immunotherapy in the treatment of patients with unresectable ICC. The results demonstrated that this regimen exhibited promising efficacy, with manageable adverse events and complications. Additionally, these results also offer a potential novel first-line treatment option for this patient population. Based on the results of this study, future phase III clinical trails are warranted to validate the outcomes. Clinical trial information: ChiCTR2500112123. Research Sponsor: Haiyan Foundation; Beijing Medical Award Foundation.

A phase I trial on the safety, tolerance, and preliminary efficacy of intracavitary injection of in situ vaccines (FOLactis) in patients with advanced solid tumors complicated with malignant pleural effusion. First Author: Lifeng Wang, The Comprehensive Cancer Center of Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing, China

Background: Malignant pleural effusion (MPE) is caused by the metastasis of malignant tumors to the pleura. Traditional treatment have limited efficacy. In our preliminary research, a recombinant lactobacillus expressing the fusion protein Flt3L-OX40L (enhancing antigen-presenting function of dentritic cells and activation of antigen-specific T cells) named FOLactis was proved to have strong anti-tumor effect in early clinical trials. This clinical study was designed to explore the safety and efficacy of intracavitary injection of FOLactis for the treatment of malignant pleural effusion (NCT06512896). **Methods:** This is a single arm, single center study. In addition to systemic treatment, participants received intracavitary 2-4 injections of FOLactis. Primary endpoint was safety; secondary endpoints included Objective response rate of pleural effusion and the duration time of pleural effusion control. **Results:** From June 2023 to Oct 2025, a total of 38 patients were intracavitary injected with FOLactis, of which 29 patients completed more than 2 injections. Among these patients, the adverse reactions included Grade I-II fever (12/38, 31.6 %), chest wall pain (9/38, 23.68%), fatigue (2/38, 5.26%), and pneumothorax (1/38, 2.63%), while no adverse events above grade III were observed. Among the 38 patients with local treatment efficacy evaluation, 10 patients had complete disappearance of pleural effusion (10/38, 26.32%), 24 patients had reduction of pleural effusion (24/38, 63.16%), 4 patients had no significant change in pleural effusion (4/38, 10.53 %). Up to the current date, there are 21 patients whose pleural effusion has been controlled for more than one year. Among them, one patient with with advanced lung adenocarcinoma have had their pleural effusion controlled for over 30 months and is still under follow-up. It was found that patients with reduced pleural effusion had higher baseline secretion levels of IL-5 (P=0.0217), TNF-a (P=0.0178) and IFN-a (P=0.0278) in pleural effusion, while those with significantly increased levels of IL-6 (P=0.0076), IL-1B (P=0.0009) and IL-8 (P=0.0198) after treatment also had better control of pleural effusion. Further analysis of RNA sequencing in the pleural fluid of 15 patients revealed that patients with better therapeutic effects showed upregulation of $CD4^+$memory T cells, lymphoid precursor cells, $CD8^+$effector memory T cells and an upward trend in immune microenvironment scores after treatment. **Conclusions:** This ongoing phase I study with intracavitary injection of FOLactis in patients with malignant pleural effusion has preliminarily confirmed safety and clinical efficacy, which suggested to be a promising immunotherapeutic strategy for the effective control of malignant pleural effusion. Clinical trial information: NCT:06512896. Research Sponsor: None.

2602 **Poster Session**

Safety and efficacy of intratumoral (IT) ruxotemitide (LTX 315) in combination with pembrolizumab in patients with unresectable advanced melanoma or triple-negative breast cancer (TNBC). First Author: Stephane Dalle, Centre Hospitalier Universitaire de Lyon, Pierre-Bénite, France

Background: Advanced unresectable cutaneous melanoma or TNBC are associated with poor prognosis and limited treatment options. Ruxotemitide is an oncolytic peptide that induces immunogenic cell death and reshapes the tumor microenvironment to boost antitumor immune responses. We report aggregate safety and efficacy from two trials that assessed intratumoral ruxotemitide combined with pembrolizumab in patients with advanced or metastatic melanoma or TNBC. **Methods:** Two studies enrolled respectively patients with melanoma stage IIIB–IV (M1b) or unresectable TNBC and at least one injectable lesion (as cutaneous, subcutaneous or lymph node). Patients with melanoma were required to have failed prior PD-1\PD-L1 blockers treatment while TNBC patients were naïve of immunotherapy. Patients were required to have adequate organ function. Patients received IT ruxotemitide (up to seven injections during the first 29 days) in combination with pembrolizumab 200 mg IV every 3 weeks until disease progression or for up to 24 months. Safety and efficacy were analyzed across both studies. Tumor assessments were based on RECIST v1.1. **Results:** 41 patients were enrolled, with a median age of 61 years. 26 of pts (63.4%) had received three or more prior lines of therapy, and 22 pts (53.7%) had previous checkpoint blockade treatment. 22 patients (53.7%) had melanoma, 18 patients TNBC (43.9%) and 1 patient (2.4%) a carcinoid tumor. 4 patients had a partial response (2 with melanoma and 2 with TNBC). All responses in melanoma patients were durable, lasting more than 24 months. 1 patient with TNBC achieved a PR for one year. The safety profile was consistent with known effects of IT immunotherapy and pembrolizumab. The most common treatment emergent adverse events (TEAEs) related to ruxotemitide were injection-site reactions (78%), injection site erythema (26.8%), fatigue (22%), hypotension, injection site swelling or pruritus (14.6% each). Grade 3 TEAEs related to ruxotemitide included injection site pain (19.5%) and hypertension (4.9%). There were no related grade 4 TEAEs or deaths. **Conclusions:** IT ruxotemitide plus pembrolizumab demonstrated durable antitumor activity and manageable safety in heavily pretreated patients with advanced or metastatic melanoma or TNBC with injectable disease. These findings support further clinical evaluation of this combination in melanoma and TNBC. Clinical trial information: NCT01986426 and NCT04796194. Research Sponsor: None.

A phase I window-of-opportunity trial of intraperitoneal, intratumoral lipopolysaccharide in peritoneal metastases: Safety and immune remodeling from the RIOT-1 study. First Author: Christopher Sherry, Allegheny Health Network Cancer Institute, Allegheny Health Network, Pittsburgh, PA

Background: Peritoneal metastases (PM) from gastrointestinal malignancies exhibit immune exclusion and limited responsiveness to systemic immunotherapy. Regional intratumoral immune activation may reprogram the tumor microenvironment (TME). RIOT-1 evaluated the safety, feasibility, and biological effects of intraperitoneal intratumoral lipopolysaccharide (LPS), a Toll-Like Receptor-4 (TLR4) agonist, administered during diagnostic laparoscopy. **Methods:** RIOT-1 (NCT05751837) was a single-center, open-label Phase I window-of-opportunity trial. Twelve patients with appendiceal or colorectal PM received paired intratumoral injections of 1 μg E. coli O113-derived LPS and normal saline into spatially distinct tumor deposits at laparoscopy, followed by planned cytoreductive surgery 14 days later. The primary endpoint was safety. Secondary endpoints included immune and molecular remodeling assessed by immunohistochemistry (IHC), PhenoCycler multiplex immunofluorescence, spatial neighborhood analysis (CytoMAP), and high-resolution mass-spectrometry proteomics. Key proteomic findings were validated by targeted IHC staining. **Results:** Intratumoral LPS administration was feasible and well tolerated, with no grade $\geq$3 adverse events and no interference with subsequent cytoreductive surgery. IHC demonstrated significant post-LPS increases in M1-like macrophages ($CD68^+CD86^+$), M2-like macrophages ($CD68^+CD206^+$), and $CD1a^+$ antigen-presenting cells (all $p<0.05$). PhenoCycler and CytoMAP analyses revealed LPS-specific reorganization of the immune microenvironment, characterized by enrichment of myeloid- and APC-dominant neighborhoods and altered tumor–immune spatial relationships compared with saline-injected controls. Proteomic profiling quantified 5,178 proteins and revealed LPS-specific enrichment of neutrophil degranulation, cytokine-mediated signaling, RNA translation, and autophagy–lysosomal pathways, distinct from biopsy/carrier-associated structural remodeling observed with saline. Upregulated proteins including LYZ, FCER1G, NAIP, and CD68 were confirmed by IHC, supporting localized innate immune activation and metabolic reprogramming. **Conclusions:** Intraperitoneal intratumoral LPS delivery in PM is safe and biologically active, inducing reproducible innate-dominant immune and metabolic remodeling validated across spatial, proteomic, and histologic platforms. These data establish clinical proof-of-mechanism for regional TLR4 agonism and support further dose-optimization and rational combination strategies in peritoneal malignancies. Clinical trial information: NCT05751837. Research Sponsor: ACPMP.

Clinical translation of PeptiCRAd-1: Interim clinical evaluation of a modular oncolytic adenovirus vaccine platform targeting NY-ESO-1 and MAGE-A3 in advanced solid tumors. First Author: Lukasz Kuryk, Valo Therapeutics, Helsinki, Finland

Background: Oncolytic viruses can convert poorly immunogenic tumors into inflamed, immune-responsive lesions, but clinical benefit is often limited by insufficient induction of tumor antigen–specific T cells. PeptiCRAd-1 is a novel peptide-guided oncolytic adenoviral immunotherapy designed to deliver tumor antigens while providing intrinsic immune stimulation. It consists of a conditionally replicating adenovirus expressing CD40L and OX40L and coated with NY-ESO-1 and MAGE-A3 peptides to enhance priming of antigen-specific adaptive immunity. **Methods:** VALO-001 (NCT05492682) is an ongoing, open-label, non-randomized phase 1 trial enrolling adults with injectable advanced solid tumors expressing NY-ESO-1 and/or MAGE-A3, including melanoma, TNBC, NSCLC, sarcomas, and colorectal cancer. Treatment includes low-dose cyclophosphamide followed by intratumoral PeptiCRAd-1 prime/boost injections combined with pembrolizumab. Primary objectives are safety and tolerability; secondary/exploratory endpoints assess innate and adaptive immune activation: antigen-specific T-cell induction, tumor-infiltrating lymphocyte (TIL) density, viral shedding, and preliminary antitumor activity. Immune monitoring includes cytokine profiling, ELISpot for NY-ESO-1/MAGE-A3 responses, and paired biopsies for multiparametric immunophenotyping. **Results:** Seven patients have been enrolled and treated in the START Phase 1 evaluation of PeptiCRAd-1: five in the intratumoral (i.t.) cohort and two in the combined intratumoral plus subcutaneous (i.t. + s.c.) cohort. Across both groups, study treatment has been feasible and well tolerated, with no dose-limiting toxicities, treatment-related serious adverse events, or unexpected safety signals reported to date. In the i.t. cohort, innate immune activation occurred in 3/5 patients; NY-ESO-1/MAGE-A3-specific T-cell responses in 3/5; and increased TILs in 4/5. Clinical responses were observed in 2/5, with disease control in 3/5 patients. Early i.t. + s.c. data show markedly stronger peptide-specific T-cell responses than i.t. alone, supporting combined local–systemic immunization. This cohort remains open, with eight additional patients required. Across evaluable patients, biopsies demonstrated increased TIL density, and early antitumor activity—including partial responses and durable stable disease—was observed across multiple tumor types. **Conclusions:** PeptiCRAd-1 shows a favorable safety profile and induces coordinated systemic and intratumoral immune activation in advanced solid tumors. Robust antigen-specific T-cell responses and enhanced TIL infiltration support its potential to strengthen antitumor immunity and justify continued evaluation, including combination with PD-1 blockade. Clinical trial information: NCT05492682. Research Sponsor: None.

2605 **Poster Session**

BI-1808 + pembrolizumab: Responses to a chemotherapy-free regimen in advanced ovarian cancer. First Author: Anja Williams, Sarah Cannon Research Institute, London, United Kingdom

Background: Up to 80% of individuals with advanced ovarian cancer experience disease progression after standard platinum-based chemotherapy, leaving few approved therapeutic options and poor prognosis. Anti-PD-1 therapies such as pembrolizumab have shown modest efficacy in recurrent ovarian cancer as single agent therapy with an ORR of 8% (KEYNOTE-100), while adding pembrolizumab to weekly paclitaxel$\pm$bevacizumab regimen (KEYNOTE-B96) demonstrates statistically meaningful improvement in OS and PFS in all comers and the PD-L1 CPS $\geq$1 population. BI-1808 is an IgG1 mAb targeting TNFR2. It blocks TNF-α binding and, via FcγR engagement, depletes Tregs and reprograms myeloid cells, expanding antitumor CD8+ T cells. These mechanisms of action differentiate BI-1808 from the relief of T cell suppression mediated by anti-PD1. Accordingly, in preclinical models BI-1808 synergizes with anti-PD-1 leading to an additive tumor inhibition. During BI-1808 monotherapy exploration, one case of complete response in a platinum-resistant patient was observed. The combination of BI-1808 and pembrolizumab could offer a chemotherapy-free treatment alternative in ovarian cancer. **Methods:** Safety and efficacy of BI-1808 plus pembrolizumab are being evaluated in patients with advanced pretreated ovarian cancer in a sub-cohort of the ongoing Phase 2a trial (19-BI-1808-01). The signal-seeking cohort aimed to enroll 20 patients at BI-1808 1000 mg Q3W plus pembrolizumab 200 mg Q3W, followed by dose optimization. **Results:** As of Dec 18, 2025, 24 subjects received BI-1808 plus pembrolizumab. Among 17 response-evaluable patients, 4 achieved confirmed partial response (ORR 24%). Disease control rate was 65%, with 7 patients showing prolonged stable disease, several ongoing beyond 10 months. Strong activity was observed in both high-grade serous and clear cell subtypes. The combination was generally safe and well tolerated; immune related events were manageable and did not lead to treatment discontinuation. Analysis of circulating immune cells shows significant T reg depletion and strong signs of $CD8^+$ T cell activation. **Conclusions:** Early data from this cohort are highly encouraging, with ORR 24% and DCR 65%. BI-1808 plus pembrolizumab demonstrated a manageable safety profile and promising activity in advanced heavily pretreated ovarian cancer. Based on these findings, the cohort will expand by 20 additional patients focusing on clear cell and high-grade serous subtypes. Further data, including biomarker analyses, will be presented on poster. Clinical trial information: NCT04752826. Research Sponsor: None.

Neoadjuvant chemokine modulation of the tumor microenvironment (TME) in resectable metastatic colorectal cancer: Results from a phase I study. First Author: Sarbajit Mukherjee, Miami Cancer Institute, Miami, FL

Background: Our preclinical studies using ex vivo explant cultures of resected metastatic colorectal cancer (CRC) tissues and in vivo mouse models showed that the combination of interferon alpha (IFNα) with toll-like receptor-3 (TLR-3) ligands and inhibitors of prostaglandin synthesis selectively induces effector T cell-attracting chemokines (CXCL9, CXCL10, CXCL11, and CCL5) in tumor microenvironments (TME), but not in adjacent healthy tissues, allowing for their systemic application to modulate TME. The chemokine-modulating (CKM) regimen, consisting of IFNα, rintatolimod (a selective TLR3 agonist), and celecoxib (a COX-2 inhibitor), also suppresses CCL22, a Treg-attracting chemokine in the TME. Based on these preclinical data, we hypothesized that a systemic CKM regimen would be safe and effective in modulating the TME of metastatic CRC. **Methods:** Nine chemotherapy-naïve patients with metastatic or recurrent CRC confined to the abdomen/pelvis and expected to have a complete resection received increasing doses of IFNa2b in a Phase I study to establish a recommended phase II dose of CKM for efficacy studies. The adaptive dose-escalation evaluated IFNα2b at 5, 10, and 20 million units (MU)/m2/day IV (Monday–Friday for 1 week pre-surgery), in combination with fixed doses of rintatolimod (200 mg IV; Monday–Friday) and celecoxib (200 mg orally twice daily; Monday–Friday). **Results:** No dose-limiting toxicities were observed, and 20 MU/m² of IFNα2b was identified as the recommended Phase II dose. All treated patients underwent R0 resection, as planned. Common treatment-related adverse events were flu-like symptoms (chills, fever, fatigue) and transient laboratory abnormalities (anemia, leukopenia), mostly grade 1–2. Two patients (13%) developed grade 3–4 neutropenia, which resolved without sequelae. There were no unexpected perioperative complications attributable to the regimen. Preliminary analysis of resected tumor tissues showed evidence of immune modulation in CKM-treated patients: increased ratios of CD8+ CTLs to FoxP3+ Tregs, with concomitant elevation of the effector chemokines (CCL5 and CXCL10), along with reduced expression of the Treg-recruiting chemokine CCL22, compared to 77 patients undergoing upfront tumor resections. **Conclusions:** Neoadjuvant CKM regimen is safe and feasible in resectable metastatic CRC and is associated with improved ratios of CD8+ CTLs to FoxP3+ Tregs in the TME. Further studies combining CKM with immune checkpoint inhibitors and/or chemotherapy are warranted to evaluate the impact of preoperative TME modulation on long-term oncologic outcomes in CRC. Clinical trial information: NCT01545141. Research Sponsor: National Cancer Institute; P01CA132714; National Cancer Institute; P01CA234212.

Safety and efficacy results from a first-in-human, phase 1/2 study of ASKG915, an anti-PD-1/pro-IL-15 bifunctional fusion protein, for patients with advanced solid tumors. First Author: Jiajia Li, Fudan University Shanghai Cancer Center, Shanghai, China

Background: ASKG915 is a bifunctional fusion protein of PD-1 antibody fused with an IL-15 prodrug. Preclinical studies demonstrated the efficacy of ASKG915 in neoplastic models. Here, we present updated safety and efficacy results from a first-in-human, dose escalation and dose expansion of ASKG915 monotherapy in patients (pts) with advanced solid tumors. **Methods:** This open-label, multicenter, Phase 1/2 study in adult pts with advanced unresectable or metastatic solid tumors (NCT05867420) comprised two parts: dose escalation (Part 1) and dose expansion (Part 2). Pts with advanced solid tumors that were resistant/refractory to current standard treatment, and with at least 1 measurable lesion per RECIST 1.1, were eligible. The primary objective was safety. Secondary objectives included efficacy, pharmacokinetics, pharmacodynamics, and immunogenicity. **Results:** As of December 30, 2025, we have treated 104 pts at dose-escalation phase (n=19) and dose expansion phase (n=85). Primary tumor types included NSCLC (n=48, 46.2%), CRC (n=35, 33.6%), ovarian cancer (n=11, 10.6%), cervical cancer (n=4, 3.8%) and others (n=6, 5.8%). Most pts (83/104, 79.8%) had received two and more lines of prior treatment, and 71 pts (68.3%) had undergone previous immunotherapy. No dose-limiting toxicities was observed in dose escalation phase, and the maximum tolerated dose has not been reached up to 3 mg/kg. In SS set, any-grade treatment-related adverse events (TRAEs) were reported in 98/104 (94.2%) pts, with the most common being rash (39/104, 37.5%), anemia (37/104, 35.6%), and elevated aspartate aminotransferase (19/104, 18.3%). ASKG915 monotherapy exhibited dose-dependent efficacy across dose levels. In the EFR cohort, encouraging antitumor activity was observed at the mid-dose level or above in both late-line NSCLC that had progressed on prior immunotherapy and MSS CRC: a 30% confirmed partial response (PR) rate (3/10) in non-liver metastatic MSS CRC at the mid-dose level or above, and a 30% PR rate (3/10) in NSCLC patients at the high-dose level. Further efficacy data will be presented at the time of the conference. CD8+ T and NK cells demonstrated proliferative expansion at mid-to-high doses. Drug plasma exposure increased dose-dependently with low activated ASKG915 levels and no ADA impact after repeat dosing. **Conclusions:** ASKG915 demonstrated a promising clinical efficacy in pts with MSS CRC and NSCLC, with a well-tolerated safety profile. These results support further evaluation of ASKG915 as a monotherapy and in combination therapies. Clinical trial information: NCT05867420. Research Sponsor: None.

RAISIC-1: A phase 1/2 clinical trial of the GPR65 inhibitor PTT-4256—Preliminary safety, tolerability, pharmacokinetic, and pharmacodynamic results. First Author: Ganessan Kichenadasse, Southern Oncology Clinical Research Unit, Bedford Park, SA, Australia

Background: The acidic tumor micro-environment is linked to immune suppression and insensitivity to immunotherapy. The G protein-coupled receptor, GPR65, is activated in this low pH environment, driving the increased transcription of myeloid immune-suppressive genes and reduced transcription of T- and NK-cell functional and effector genes. Against the backdrop of this target validation, PTT-4256, a first-in-class, potent, orally-bioavailable, allosteric, small molecule inhibitor of GPR65, is being developed as a potential treatment of solid tumors. In mouse syngeneic cancer models, oral administration of PTT-4256 as monotherapy delivers pronounced efficacy, which is enhanced in combination with an anti-PD-1 antibody. Transcriptomic analysis shows that PTT-4256 effectively reverses the acidic immune suppression in mice tumors. **Methods:** RAISIC-1 is a multi-modular Phase 1/2 clinical trial in adults with histologically confirmed advanced/metastatic solid malignancies who have previously received standard of care therapies. Phase 1 (Module A) is aimed to evaluate safety (treatment emergent and related adverse events – TEAE/TRAE; dose limiting toxicity – DLT; maximum tolerated dose-MTD), pharmacokinetics, pharmacodynamics, preliminary efficacy (as per RECIST 1.1) and estimate the optimal biological dose (OBD) / recommended Phase 2 dose (RP2D). PTT-4256 is administered orally in 21-day cycles until disease progression or unacceptable toxicity. A comprehensive biomarker program is included to detect immune-related changes in blood/plasma. **Results:** As of 7 January 2026, 14 participants (3 ongoing) have been treated with one of 5 dose-levels (10, 20, 40, 80 and 160 mg/day). PTT-4256 was well-tolerated with no DLTs. TRAEs were reported in ten participants, with fatigue (n = 8), nausea (n = 4), rash (n = 4), reduced appetite (n = 4), vomiting (n = 2) reported in more than 1 participant. All were grade 1 or 2 except one transient episode ($<$ 1 day) of grade 3 hypertension. Tumor shrinkage and stable disease have been observed at doses 40mg and above in six participants, of which two (nasopharyngeal cancer and renal cell cancer (RCC)) are ongoing in treatment $>$ 5 months. Transcriptomics and proteomics analyses show dose-dependent changes in immune-related markers in blood/plasma following PTT-4256 treatment that are consistent with preclinical data and the mode of action. **Conclusions:** Enrollment at dose levels $\geq$ 300 mg is ongoing. Phase 2 (Module B) as PTT-4256 monotherapy or in combination with anti-PD1 in RCC and head & neck squamous cell cancer (HNSCC) will commence upon identification of RP2D. Clinical trial information: NCT06634849. Research Sponsor: Pathios Therapeutics Limited.

Influence of pirfenidone on checkpoint inhibitor pneumonitis and antitumor efficacy in NSCLC: A multicenter study and mechanistic exploration. First Author: Xiaohui Jia, The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, Shaanxi province, China

Background: Checkpoint inhibitor pneumonitis (CIP) is a major fatal immune-related adverse events (irAEs) in immune checkpoint inhibitor (ICI) therapy, accounting for ~35% of fatal irAE-related deaths. Patients with pre-existing interstitial lung disease (ILD) face markedly higher CIP risk and are routinely excluded from ICI treatment, depriving them of antitumor benefits. Current first-line glucocorticoid therapy for CIP are limited by inadequate efficacy in fibrotic-stage or steroid-resistant CIP and impaired ICI activity. As a drug-induced interstitial pneumonitis, CIP shares pathological similarities with ILD. Pirfenidone, an approved ILD drug, showed potential efficacy in CIP case reports, but its systematic clinical value and mechanisms remain unvalidated. This study aimed to elucidate pirfenidone's role in full-cycle CIP management and its synergistic antitumor effect with ICIs. **Methods:** A multicenter retrospective study enrolled advanced non-small cell lung cancer (NSCLC) patients receiving first-line ICI-based therapy from three hospitals between 2018 and 2024, stratifying into pirfenidone+ICI+chemotherapy (Pirf+ICI+chemo) and ICI+chemotherapy (ICI+chemo) groups. Primary endpoint was CIP incidence, secondary endpoints objective response rate (ORR) and progression-free survival (PFS). For mechanistic studies, bleomycin and ICI were administered to spontaneous NSCLC mice to mimic clinical ICI treatment in ILD-high-risk patients, generating a CIP mouse model. Lung scRNA-seq defined pirfenidone's role in CIP management and synergistic antitumor activity. **Results:** Of 141 enrolled patients, Pirf+ICI+chemo had significantly lower CIP incidence vs. ICI+chemo (34.01% vs. 59.57%, p=0.0070), with synergistic antitumor effects manifested as higher ORR (78.72% vs. 60.64%, p=0.0376), and longer median PFS (9.97 vs. 5.47 m, p=0.0120). CIP shows a biphasic inflammation-fibrosis pathology. scRNA-seq of 62,335 lung cells identified ISG^+ aged neutrophils (ISG^+ Na) as the key pathogenic driver of CIP progression. ICI-induced excessive immune activation triggers lung damage, activating the IFN-I-IRF9/STAT1 axis to promote ISG^+ Na differentiation. These cells secrete IL-6, IL-8, TNF-α to amplify inflammation, and TGF-β to induce fibroblast proliferation and activation, all of which pirfenidone blocks, supporting its full-cycle CIP efficacy mechanistically. Animal experiments further confirmed pirfenidone's robust efficacy in CIP prevention, treatment and synergistic antitumor activity with ICI. **Conclusions:** Pirfenidone reduces CIP incidence and synergizes with ICI therapy to enhance antitumor efficacy. Mechanistically, it targets IFN-I-IRF9/STAT1-ISG^+ Na axis for dual clinical benefits. These findings confirm pirfenidone as a translatable strategy to balance CIP control and antitumor activity. Research Sponsor: None.

Intratumoral injection of IP-001 following thermal ablation in patients with advanced solid tumors: A multicenter phase Ib/IIa trial with expansion cohorts in melanoma and soft tissue sarcoma patients (SAKK 66/17). First Author: Markus Joerger, Health Ostschweiz (HOCH), St. Gallen, Switzerland

Background: This trial combines the novel adjuvant immunomodulator IP-001, a glycan polymer, with laser ablation in patients with relapsed solid tumors. **Methods:** This is a non-randomized, open-label multicenter phase Ib/IIa trial with a dose-finding part 1 and a dose expansion part 2 in advanced melanoma and soft tissue sarcoma (STS). Primary objectives include the safety and tolerability of up to six 4-weekly cycles of intratumoral IP-001 following laser ablation (TRANBERG Thermal Therapy System, Clinical Laserthermia System AB), and 12-week disease control rate (12w-DCR) according to RECIST v1.1 in advanced melanoma. The dose-finding part used 4 mL of IP-001 (10 mg/mL). The activity endpoint for advanced melanoma used the 1st stage of a Simon 2-stage design, with 12w-DCR $\leq$20% (H0) vs. $\geq$40% (H1) (type-I error 0.05, power 80%). **Results:** We treated 15 melanoma and 10 STS patients, including 4 in part 1 (n=28). Median age was 62 years, 57% were male, all patients had metastatic disease, including 60% with liver metastases. Most patients (78%) had received $\geq$3 prior lines of systemic treatment, including 79% with prior immunotherapy. Treatment was well tolerated with no dose-limiting toxicity, and a recommended IP-001 dose of 4 mL. Patients received a median of 2 (range 1 to 6) cycles of study treatment. Reasons for treatment discontinuation included physician's decision (39%) and disease progression (25%). 27 patients (96%) experienced treatment-emergent adverse events (TEAE). IP-001-related TEAE occurred in 16 (57%) patients, including 5 (17%) patients with severe IP-001-related TEAE. Severe TEAE occurred in 20 (71%) patients overall. Most frequent mild IP-001-related TEAE included fever (36%), fatigue (21%), rash (14%), hypotension (11%), injection site reactions (11%) and flu-like symptoms (7%); 2 cases (7%) of severe allergic reactions were reported, including one serious reaction. Allergic reactions occurred at cycle 3 in both patients and resolved without sequelae. Treatment discontinuation for TEAE occurred in a single patient (4%). 12w-DCR in advanced melanoma was 21% (3/14 evaluable patients) (2-sided 90% CI: 6%, 46%), with stable disease in 50% and partial remission (PR) in one (7%) melanoma patient. 15 (53%) patients had radiological tumor shrinkage in $\geq$1 untreated tumor lesion. Median progression-free survival (PFS) in advanced melanoma was 3 months, with a 12-month PFS rate of 33%, indicating preliminary evidence of disease control beyond the 12-week primary endpoint window. **Conclusions:** Intratumoral IP 001 at a dose of 4 mL following thermal ablation is well tolerated, with mainly mild, transient immune-related events. Although the pre-specified activity endpoint was not met, the observed DCR and PFS support further evaluation of this novel immuno-oncologic strategy. Clinical trial information: NCT03993678. Research Sponsor: Immunophotonics, Inc., St. Louis MO, 63110, U.S.

2612 **Poster Session**

Potential effects of TGF-β inhibition on immune resistance by targeting immunosuppressive microenvironment in advanced gastric cancer (AGC): Multi-omics post-hoc analysis of the K-Umbrella-06 trial. First Author: Choong-kun Lee, Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: TGF-β signaling promotes immune exclusion by driving fibrosis and hindering T-cell infiltration. We performed multi-omics post-hoc analyses of K-Umbrella-06 to identify mechanisms and predictive biomarkers for TGF-β/PD-L1 dual blockade in HER2-negative AGC. **Methods:** K-Umbrella-06 (NCT04835896) was an investigator-initiated, single-arm, phase Ib/II study enrolling HER2-negative AGC pts who had progressed on 1st-line treatment. Pts received bintrafusp alfa (TGF-β trap/anti–PD-L1) and weekly paclitaxel. Pretreatment H&E whole-slide images (WSIs) were analyzed with an AI-powered WSI analyzer to quantify fibroblast and endothelial cell (EC) densities and immune phenotypes. A separate cohort treated with nivolumab + paclitaxel (n=26) served as a control. Integration of baseline tissue transcriptomics and serial ctDNA sequencing (baseline, 1st RECIST assessment, and progression) was performed to identify predictive biomarkers and resistance mechanisms. **Results:** At a median follow-up of 46 months in 30 enrolled patients, the mPFS and mOS were 3.8 and 8.9 months, respectively; notably, 5 patients achieved durable responses with PFS exceeding 3 years. AI-WSI analysis revealed that high fibroblast density (≥median) was a significant predictor of superior outcomes (mPFS: 4.3 vs. 2.0 months, HR 0.29, P=0.007; mOS: 20.4 vs. 5.8 months, HR 0.28, P=0.012). Conversely, patients with higher intratumoral EC density had shorter mPFS (2.0 vs. 5.9 months, HR 2.29, P=0.058) and mOS (4.0 vs. 8.9 months, HR 1.61, P=0.285). Notably, patients with the immune-excluded phenotype achieved a higher ORR (60.0% vs. 18.2%) and prolonged survival compared to inflamed/desert types. These biomarkers were not predictive in the nivolumab + paclitaxel cohort, suggesting a TGF-β specific effect. Transcriptomic profiling of responders showed enrichment in TGF-β signaling (normalized enrichment score [NES] 2.87, P<0.001) and SMAD2/3 activity (NES 2.99, P<0.001), alongside increased naive CD8+ T cells and inflamed EC cells. Conversely, non-responders exhibited higher M2 macrophage and abundant angiogenic tip cells. Serial ctDNA analysis identified emergent TGF-β pathway alterations as a potential mechanism of acquired resistance (OR 7.30, P=0.08). **Conclusions:** Integrated AI-WSI, transcriptomic, and longitudinal ctDNA analyses suggest that TGF-β pathway activation and an immune-excluded phenotype are associated with clinical benefit from bintrafusp alfa plus paclitaxel, and may identify a responder subset distinct from conventional PD-1/PD-L1–based therapy. These findings support further evaluation of anti–TGF-β strategies for AGC with an immunosuppressive tumor microenvironment. Clinical trial information: NCT04835896. Research Sponsor: Merck KGaA.

2613 **Poster Session**

Effects of SECN-15, a neuropilin-1–targeting antisense oligonucleotide, on resistance to immune checkpoint inhibitors in preclinical tumor models. First Author: Richard Klar, Secarna Pharmaceuticals, Planegg, Germany

Background: Neuropilin-1 (NRP1) is a transmembrane co-receptor implicated in tumor growth, metastasis, angiogenesis, and immune suppression. High NRP1 expression is associated with poor prognosis in multiple solid tumors, including gastric cancer (GC) and breast cancer. SECN-15 is a high-affinity antisense oligonucleotide (ASO) designed to selectively downregulate NRP1. In light of recent clinical success of combined PD-1/PD-L1 and anti-angiogenic strategies and given its dual role in angiogenesis and immune suppression, NRP1 represents an attractive target to overcome resistance to immune checkpoint inhibition. **Methods:** NRP1-specific ASOs were identified using the OligoCreator platform. Anti-tumor efficacy was assessed following systemic administration in multiple syngeneic mouse tumor models, both as monotherapy and in combination with immune checkpoint inhibitors. Target engagement was evaluated at the RNA level in tissues and at the protein level in plasma via soluble NRP1 quantification. In silico analyses of patient transcriptomic datasets were conducted to prioritize indications for clinical development. PK/PD characterization and dose optimization studies are currently underway to support dose selection for GLP toxicology studies and first-in-human evaluation. **Results:** Systemic administration of SECN-15 achieved robust target knockdown in tumors across multiple cell populations and modulated the tumor microenvironment, including downregulation of extracellular matrix and EMT genes. A single dose resulted in near-complete and sustained suppression of plasma soluble NRP1 levels for up to 28 days, consistent with durable target engagement. SECN-15 delayed tumor growth as monotherapy, with complete regressions observed in a subset of animals, and significantly enhanced anti-tumor activity in combination with immune checkpoint inhibitors in models with limited responsiveness to checkpoint blockade alone. Single-cell RNA-seq analyses from gastric cancer patients identified endothelial cells and macrophages as major NRP1-expressing populations, with NRP1high subsets exhibiting TGF-β, hypoxia, and EMT pathway activation and suppression of allograft rejection signatures, consistent with an immunosuppressive, pro-angiogenic tumor microenvironment. In silico analyses showed that high NRP1 expression correlates with poor survival and advanced disease stage in gastric cancer, supporting its prioritization for clinical development. **Conclusions:** Targeting Neuropilin-1 with the ASO SECN-15 remodels the tumor microenvironment and enhances responsiveness to immune checkpoint blockade, supporting NRP1 inhibition as a strategy to overcome resistance to ICI therapy in solid tumors. The program is approaching IND-enabling development to support the clinical translation of SECN-15. Research Sponsor: Secarna Pharmaceuticals GmbH & Co. KG.

Non-invasive characterization of intratumoral CD8+ T cells using standard-of-care (SOC) CT and ^{89}Zr-crefmirlimab berdoxam PET (CD8-PET) radiomic signature in solid tumors. First Author: Jayant Narang, Takeda Pharmaceuticals, Cambridge, MA

Background: Noninvasive estimation of intratumoral CD8+ T-cell density using radiomics may enhance comprehensive immune profiling and support immuno-oncology development and treatment decisions. We evaluated the feasibility of using a multimodality radiomic approach incorporating SOC CT and CD8-PET/CT to characterize CD8+ T-cell density in solid tumor lesions. **Methods:** 71 soft-tissue lesions from 52 patients with solid tumors enrolled in a Phase II iCorrelate trial (NCT03802123) were retrospectively analyzed. Patients received a pre-treatment CD8-PET/CT scan (ImaginAb, Inc) before initiating SOC immunotherapy (IOT) and a second CD8-PET/CT scan on-treatment 4-8 weeks later, with selection of biopsied tumor lesions of known CD8+ T-cell density for radiomic analysis. Radiomic features were extracted from volumetric segmentations of these tumor lesions using 3D Slicer on Diagnostic contrast CT (DCT, n=27), CT attenuation correction (CTAC; n=71), and CD8 PET (n=71) images. Features were integrated with acquisition parameters, lesion location, and adenopathy status. Feature selection used maximum relevance–minimum redundancy and variance inflation factor methods. Elastic-Net classifiers were trained to predict binarized (median split at the 328 cells/mm^2 level) CD8+ T-cell density, with hyperparameter optimization via grid search and 5 fold Cross-Validation (CV). In each iteration of the CV, 1 fold (20%) was left out and models were trained on the remaining 4 folds (80%). Model performance was assessed using AUC and F1 score. **Results:** In the test set, Multimodality models (CTAC+DCT+PET) outperformed single-modality (AUC up to 0.94 vs. 0.80), with improved AUC and F1 scores and robust performance across endpoints. Single-modality models achieved AUCs of 0.76 (F1 0.55) for DCT, 0.80 (F1 0.72) for CTAC, and 0.80 (F1 0.70) for PET. The combined CTAC+DCT+PET model demonstrated superior performance with a test AUC of 0.85 (F1 0.79) and training AUC of 0.94 (F1 0.89). Application of previously reported DCT radiomic weights (Sun et al.) to this cohort yielded a lower AUC of 0.68, compared with the multimodality model. **Conclusions:** This study demonstrates robust radiomics-based characterization of intratumoral CD8+ T-cell density in patients with solid tumors is feasible using non-invasive multi-modality approach utilizing CD8-PET and SOC CT scans. These findings may lead to further clinical adoption and non-invasive monitoring of the tumor immune microenvironments with CD8-PET and SOC CT scans using radiomics, informing IOT decision-making, and enhancing patient stratification in both clinical development and routine oncology practice. Validation in larger, multicenter cohorts is still required to confirm generalizability and robustness of these radiomic signatures. Clinical trial information: NCT03802123. Research Sponsor: None.

2615 **Poster Session**

PhaseX as a phase 0.9 translational platform to de-risk BiTE immunotherapy through mechanistic patient explant profiling. First Author: Kanishka Fernando, National Cancer Centre Singapore, Singapore, Singapore

Background: Bispecific T-cell engagers (BiTEs) redirect cytotoxic T cells to tumor cells, but responses in solid tumors remain heterogeneous due to antigen variability, T-cell exclusion, stromal barriers, and immunosuppressive cues within the tumor microenvironment (TME). PhaseX (patient-derived hydrogel-assisted explants) preserves native tissue architecture and endogenous immune composition ex vivo, enabling mechanistic, patient-specific interrogation of immunotherapies in a physiologically relevant context. We used PhaseX to define BiTE mechanism of action (MoA) and resolve response phenotypes in head and neck squamous cell carcinoma (HNSCC). **Methods:** Tumor explants from ~25 HNSCC patients were ex-vivo cultured in PhaseX and treated for 6 days with CD3×B7-H3 or CD3×EpCAM BiTEs with matched controls. Supernatants were collected longitudinally for multiplex secretome profiling. At endpoint, explants were dissociated and subjected to flow cytometry, while some explants were fixed and processed to FFPE sections for multiplex immunofluorescence (mIF). Cancer cells were quantified using epithelial markers (PanCK and p60). Tumor response states were classified as tumoricidal (increased tumor-cell CC3 [cleaved caspase-3] with reduced PanCK$^+$/p60$^+$ cancer cell burden) versus tumorostatic (preserved PanCK$^+$/p60$^+$ cancer cell burden with reduced Ki-67 in PanCK$^+$/p60$^+$ cancer cells). **Results:** Across both CD3×B7-H3 and CD3×EpCAM BiTE-treated explants, PhaseX captured core BiTE MoA: (i) TCR-driven activation with expansion of activated CD8$^+$ T cells (CD137$^+$) and enrichment of tumor-reactive CD8$^+$ subsets (CD137$^+$CD103$^+$CD39$^+$); (ii) immune trafficking and inflammatory programming consistent with IFN-γ signaling, evidenced by increased CXCL9/10/11 and coordinated effector cytokine signatures; and (iii) effector execution in tissue, integrating increased cytotoxic mediators (perforin, granulysin) with spatial mIF evidence of enhanced intratumoral CD8+ infiltration. Tumoricidal responders showed elevated tumor-cell CC3 with concomitant loss of PanCK$^+$/p60$^+$ tumor area, whereas tumorostatic responders showed decreased tumor-cell Ki-67 expression with comparatively limited CC3 induction, supporting biologically distinct on-treatment states. **Conclusions:** PhaseX serves as a "Phase 0.9" translational platform that preserves the TME and resolves BiTE MoA from activation to trafficking to effector execution, while distinguishing tumoricidal and tumorostatic response phenotypes. This framework supports mechanistic deconvolution, biomarker discovery, and patient stratification to de-risk bispecific antibody development. 2616 **Poster Session**

Phase 1A/B study of AB248, a CD8+ selective IL-2 mutein fusion protein, alone or in combination with pembrolizumab, in patients with advanced solid tumor malignancies. First Author: Harriet M. Kluger, Yale University School of Medicine, Smilow Cancer Center, New Haven Hospital, New Haven, CT

Background: High-dose IL-2 demonstrates modest activity in melanoma and RCC but its use is limited by severe toxicity. AB248 is a novel IL-2 fusion protein of an attenuated IL-2 mutein linked to an antibody targeting CD8β that features >500-fold selectivity for CD8+ T cells and shows strong anti-tumor activity both alone and with anti-PD1 in preclinical models. In addition to CD8+ T cell expansion and activation, the drug avoids NK cell toxicity and Treg-mediated immunosuppression. **Methods:** NCT05653882 is a phase 1A/B study investigating the safety, pharmacokinetics (PK), pharmacodynamics (PD) and anti-tumor activity of AB248 alone or with pembrolizumab in locally advanced/metastatic solid tumor malignancies, including melanoma, having previously progressed through PD-1/PD-L1 checkpoint blockade. The study's primary objective was to assess the safety and tolerability of AB248 alone and in combination with pembrolizumab. **Results:** As of December 1, 2025, 61 patients (pts.) were treated with monotherapy (MT) at 6 dose levels across 3 schedules (Q2W at 0.02mg/kg-0.75mg/kg; QW at 0.15mg/kg; Q3W at 0.3mg/kg). 68 additional pts. were treated with combo therapy (CT) at Q3W 0.15-0.3mg/kg and step-up dosing. The most common TEAEs (> 95% G1-2) among all pts. were fatigue (50%), rash (49%), nausea (43%), chills (33%), pyrexia (32%), vomiting (32%) and diarrhea (30%). Maximum tolerated doses (MTDs) were 0.5 mg/kg for MT Q2W and 0.15 mg/kg for CT Q3W. An MTD was not reached for CT step-up dosing. 41 cutaneous (cut) and mucosal (muc) melanoma pts. were evaluable for response across MT and CT dose cohorts, with 95% of pts. having received prior IO doublet therapy (anti-PD1 + anti-CTLA or anti-LAG3) and 83% having received ≥ 2 anti-PD1 regimens. Among evaluable cut melanoma pts., 2 confirmed PRs (18%) were observed among 11 pts. enrolled at higher MT dose levels (net tumor reductions of 78.8% and 87.2%) and 2 confirmed PRs (12%) were observed among 16 CT pts. (37.5% and 57.5%). Among 11 muc melanoma pts., 3 confirmed PRs (27%) were observed in CT dosing. One additional muc melanoma pt. received 0.5 mg/kg MT and remained on study with SD > 15 mos. AB248 exhibited dose-proportional PK that is comparable between MT and CT dosing. Peripheral PD data demonstrated robust and preferential CD8+ T cell expansion, with >20X expansion in MT (0.3 mg/kg and above) and >11X expansion in CT dosing (0.15 mg/kg and above). Further data on safety, PK, PD, and preliminary anti-tumor activity will be presented. **Conclusions:** AB248 demonstrates robust anti-tumor activity across heavily IO-pretreated patients with metastatic melanoma (incl. mucosal melanoma). Combined with an acceptable safety profile, favorable PK and differentiated PD, the drug's anti-cancer activity merits further investigation. Clinical trial information: NCT05653882. Research Sponsor: Asherbio Therapeutics.

2618 **Poster Session**

First-in-class PD-1/IL-2$^{\alpha\text{-bias}}$ bispecific antibody IBI363 (TAK-928) in patients (pts) with advanced immunotherapy-resistant non–small cell lung cancer (NSCLC): Updated results from a phase I study. First Author: Jianya Zhou, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: IBI363 is a first-in-class PD-1/IL-2$^{\alpha\text{-bias}}$ bispecific antibody fusion protein designed to block the PD-1/PD-L1 pathway and simultaneously activate the IL-2 pathway. IBI363 selectively expands and rejuvenates exhausted tumor-specific T cells by cis-activating IL-2 receptors. It has shown a manageable safety profile and encouraging efficacy in NSCLC (No. 8509, 2025 ASCO). The updated findings are reported here with a longer follow-up. **Methods:** Pts with advanced NSCLC who had progressed on standard therapy were enrolled and received IBI363 at dose levels of 0.002/0.01/0.3/0.6 mg/kg every week, 0.3/0.6/1 mg/kg Q2W or 1.5/2/3/4 mg/kg Q3W. Endpoints included safety, ORR, DCR, DOR and PFS assessed by investigator per RECIST v1.1, and OS. **Results:** As of Nov 20, 2025, 136 pts with NSCLC were enrolled (prior treatment lines ≥2 72.1%; including 67 with squamous NSCLC [sqNSCLC] and 66 with adenocarcinoma). The median follow-up was 14.4 months (mos, range 0.8–30.6). Both the ORR and DCR in sqNSCLC or adenocarcinoma were consistent with those reported previously. In pts with sqNSCLC at 1/1.5 mg/kg (n=28) and 3 mg/kg Q3W (n=31) (58/59 with prior IO therapy), median PFS was 5.5 (95% CI 1.5, 8.3) and 10.1 mos (6.0, 14.0), median OS was 12.5 (7.6, 22.2; maturity 71.4%) and 18.2 mos (10.7, not calculable [NC]; maturity 48.4%), with 24-month OS rate of 29.9% (14.2, 47.3) and 47.8% (28.7, 64.7), respectively. Among those who had a confirmed complete response (n=1) or partial response (PR, n=17), the overall DOR was 10.3 mos (7.0, 13.4; maturity 72.2%). In pts with *EGFR^{wt}* adenocarcinoma at 0.6/1/1.5 mg/kg (n=30) and 3 mg/kg Q3W (n=25) (all with prior IO therapy), median PFS was 2.7 (1.4, 5.1) and 4.2 mos (3.0, 7.0), median OS was 17.5 (7.1, NC; maturity 56.7%) and 15.2 mos (9.6, NC; maturity 56.0%), with 24-month OS rate of 40.2% (22.2, 57.7) and 42.7% (23.1, 61.0), respectively; the overall DOR reached 21.3 mos (4.0, 21.3; maturity 40.0%) in those achieving a confirmed objective response (n=10, all PRs). Smoking is a major factor affecting treatment efficacy in adenocarcinoma. In smokers (n=31) and non-smokers with adenocarcinoma (n=24), the median OS was 23.4 (11.3, NC; maturity 48.4%) and 11.5 mos (5.6, 19.6; maturity 66.7%), respectively. In the overall population (n=136), treatment-emergent adverse events (TEAEs) occurred in 135 pts (99.3% any grades; 48.5% ≥G3). TEAEs led to treatment discontinuation in 11 (8.1%) pts. TEAEs led to death in 5 pts (3.7%) with only 1 event (0.7%) considered treatment-related (unexplained death). The most common TEAEs were arthralgia (52.2%; 3.7% ≥G3), anemia (46.3%; 4.4% ≥G3), and rash (39.0%; 8.8% ≥G3). **Conclusions:** IBI363 was well tolerated with a manageable safety profile consistent with earlier reports, and continued to show strong and durable efficacy in pts with heavily pretreated NSCLC. Clinical trial information: NCT05460767. Research Sponsor: This study was funded by Innovent Biologics, Inc.

2619 **Poster Session**

Alirocumab plus cemiplimab in immuno-refractory metastatic NSCLC: A single-arm, multi-center, phase 2 study. First Author: Eziafa Oduah, Duke University, Durham, NC

Background: Immunotherapy resistance remains a significant unmet clinical need for most non-small cell lung cancer (NSCLC) patients. PCSK9 was shown in preclinical models to mediate cancer immunotherapy resistance and may serve as a novel immunoinhibitory target. **Methods:** This is a first-in-class, multi-center, single arm, phase II study evaluating the clinical activity and safety of the PCSK9 inhibitor, alirocumab, in combination with the anti-PD1 antibody cemiplimab, in non-small cell lung cancer (NSCLC) patients whose tumors were previously resistant to immune checkpoint blockade. The primary endpoint was objective response rate (ORR). Secondary endpoints were safety, progression free survival (PFS), overall survival (OS), duration of response (DOR) and disease control rate (DCR). The correlative objective was to analyze the biomarkers of response. **Results:** A total of 60 patients were enrolled between May 2023 and August 2025. In the 58 evaluable patients, the estimated ORR for the two-stage design was 14.98% (90% CI, 5.45, 25.52). The median duration of response was not estimable. The median OS was 7.2 months (95% CI, 5.3 – 13.6). No new safety signals were seen. Non-hematologic adverse events (AEs) were more prevalent than hematologic AEs and were predominantly grade 2 or less. Two grade 3 events were seen. Biomarker analysis identified superior outcomes in NSCLC harboring *PIK3CA, AKT1*, or *PTEN* alterations, with ORR of 31.5% (95% CI,13.9%, 68.4%,), significantly associating with response, p 0.0008 (two-sided, Fisher's exact). No objective responses were observed in the absence of *PIK3CA, PTEN* or *AKT1* alterations. Median OS was numerically longer in the altered group was 13.64 months (95% CI, 3.1 – NR) compared to 7.2 months (95% CI, 5.2-12.8) in the unaltered group. Analysis of the cancer genome atlas (TCGA) in NSCLC cohorts demonstrated a correlation between *PIK3CA, PTEN* and *AKT1* expression and PCSK9 expression. Preclinical translational studies further elucidated the impact of *PIK3CA, PTEN* or *AKT1* in intratumoral PCSK9 secretion, a novel immune-oncological finding for this pathway, and provided a biological rationale for the observed pattern of response. **Conclusions:** These findings provide clinical proof-of-principle that PCSK9 inhibition can overcome immunotherapy resistance in a subset of patients and suggest that *PIK3CA/PTEN/AKT1* pathway may play a significant role in PCSK9 mediated immune evasion and could be a biomarker of response. These findings warrant further investigation in a larger confirmatory study. Clinical trial information: NCT05553834. Research Sponsor: None.

Targeting PI3K-β to develop novel combinational therapies for melanoma. First Author: Maegan Gabby, Virginia Tech Carilion School of Medicine, Roanoke, VA

Background: Melanoma is the deadliest skin cancer, and more than 100,000 people in the United States were diagnosed in 2024. While the 5-year survival rate is 99% for localized disease, it is just 10-25% in metastasis. Treatment for metastatic melanoma often involves powerful immunotherapies (e.g. checkpoint inhibitors). However, approximately 55% of patients have innate resistance and 25% of responders develop resistance within two years. Immunotherapy resistance is due to continued checkpoint protein expression and antagonization of T-cell activation – processes controlled by the phosphatidyl inositol 3-kinase (PI3K) system. Of the four PI3K kinases (α, β, δ and γ), recent work from the Sheng lab suggests that PI3Kβ has the largest role in the growth of BRAF^{V600E}/PTEN^{null} (PI3K inhibitor) melanoma and is a prime drug target. There is an 18-residue motif found only in PI3Kβ that has close interactions with p85 - a key regulatory protein responsible for kinase activation. The Sheng lab harnessed this motif and developed a novel peptide (CPP-β18) that selectively blocks PI3Kβ with high affinity and decreases viability in cells that hyper-express PI3Kβ. Given the vital role of PI3K in immunosuppression, further investigation into CPP-β18's sensitizing effects on checkpoint inhibitors is urgently needed to lead to new therapies. **Methods:** PI3K inhibition in BRAF^{V600E}/PTEN^{null} YUMM1.7 and BRAF^{V600E}/PTEN^{WT} YUMM5.2 murine cell lines was validated by exposing cells to various commercial PI3K inhibitors and CPP-β18. Cell viability was measured via MTS colorimetric response. Advanced live-cell imaging techniques were employed to assess apoptosis when melanoma cells were treated with these selective inhibitors. Both cell lines were fluorescently labeled to differentiate cells from cytotoxic T-cells in future co-culture work. **Results:** MTS colorimetric assays reveal decreased YUMM1.7 cell viability with various PI3Kβ inhibitors (IC_{50} values = 6-10 μM) in comparison to increased YUMM5.2 cell viability (IC_{50} values = 21-30 μM). PI3Kδ and PI3Kγ inhibition had negligible effect on cell survival. YUMM1.7 cell death (>70%) was also demonstrated when treated with the novel CPP-β18 peptide inhibitor. Live cell imaging studies confirm feasibility to investigate interactions between drug therapy and melanoma cells and to appreciate early and late stages of apoptosis on a cellular level. Both cell lines are successfully fluorescently labeled to undergo further drug challenge experiments. **Conclusions:** Our data strongly supports CPP-β18 as a potential drug therapy to augment checkpoint inhibitor efficacy and mitigate the development of resistance. Cell line validation demonstrates increased PI3K activity with deleted PTEN and decreased viability when challenged with PI3Kβ inhibitors. Selectively blocking PI3Kβ via CPP-β18 may augment checkpoint inhibitors and mitigate resistance, giving patients improved treatment options. Research Sponsor: None.

Phase I/II study of concurrent intrathecal toripalimab and pemetrexed (PM) for leptomeningeal metastases (LM) from solid tumors. First Author: Guozi Yang, Cancer Center, Huizhou First Hospital Affiliated to Guangdong Medical University, Huizhou, China

Background: Intrathecal (IT) programmed death-1 (PD-1) inhibitors have demonstrated safety and feasibility in leptomeningeal metastases (LM) from melanoma or lung cancer. However, no studies have yet reported on the combination of IT PD-1 inhibitors with IT chemotherapy for LM from solid tumors. This study evaluated the feasibility and potential clinical benefit of combining IT toripalimab with pemetrexed (PM) in this patient population. **Methods:** Phase I followed a 3+3 dose de-escalation design to determine the dose-limiting toxicity (DLT) and the recommended phase II dose (RP2D). Patients received IT PM (15 mg flat dose) twice weekly for 2 weeks (induction), then weekly for 4 weeks (consolidation), followed by monthly maintenance. The administration of IT toripalimab (40 mg initial dose) was initiated concurrently with the fourth dose of IT PM, on an every-two-week schedule for 6 weeks (induction/consolidation), switching to monthly dosing during the maintenance phase. Continuation of previously administered systemic therapies was permitted during the study. The primary endpoints were RP2D and safety. Secondary endpoints included clinical response rate (CRR), disease control rate (DCR) and overall survival (OS). **Results:** From June 2024 to September 2025, 45 patients were enrolled (40 non-small cell lung cancer, 4 breast cancer, and 1 small cell lung cancer). Median age was 52 years (range 30–69), and 35 patients were female. In phase I, no DLTs were observed; the RP2D was established as toripalimab 40 mg plus PM 15 mg. All patients completed induction therapy, 42 completed consolidation therapy, and 41 received maintenance therapy. No treatment-related deaths occurred. All grade ≥3 adverse events (AEs) were attributable to IT PM, with an overall incidence of 55.6% (25/45), including leukopenia (n = 16), thrombocytopenia (n = 10), decreased hemoglobin (n = 7), and elevated hepatic aminotransferases (n = 5). Immune-related AEs were limited to grades 1-2, occurring in 24.4% (11/45) of patients, and included rash (n = 5), fever (n = 3), hypothyroidism (n = 3), and pneumonia (n = 1). According to Response Assessment in Neuro-Oncology (RANO) criteria, the CRR was 66.7% (30/45), including 11 patients with neurological dysfunction improvement, 16 with CSF cytological response, and 18 with neuroimaging improvement. The DCR was 93.3% (42/45). As of January 20, 2026, 19 patients had died. Median follow-up was 11.1 months (95% CI: 7.7–17.0). Median OS was 13.1 months (95% CI: 9.9–not applicable). **Conclusions:** IT toripalimab combined with PM showed a manageable safety profile and promising clinical activity in patients with LM from solid tumors. Based on the encouraging interim OS observed, further clinical investigation of intrathecal immunotherapy is warranted for patients with LM. Clinical trial information: NCT06462222. Research Sponsor: Huizhou Science and Technology Innovation Team Project; 2023EQ050012; Huizhou Outstanding Young Scientific and Technological Talents Program; 2025EQ050018.

Sequential or concurrent immunotherapy with locoregional radiotherapy in de novo metastatic nasopharyngeal carcinoma. First Author: Linfang Wu, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China

Background: First-line chemotherapy combined with immunotherapy (CT-IO), followed by selective locoregional radiotherapy (LRRT), has emerged as the mainstay treatment for de novo metastatic nasopharyngeal carcinoma (dmNPC). However, the efficacy of adding concurrent immunotherapy to LRRT remains controversial. **Methods:** This study enrolled patients with dmNPC who received platinum-based chemotherapy, anti–PD-1 immunotherapy, and definitive LRRT. Survival outcomes were assessed using a 12-month landmark analysis to minimize immortal time bias. Inverse probability of treatment weighting (IPTW) was employed to balance baseline characteristics between the CCRT+IO (LRRT with concurrent immunotherapy) and CCRT-IO (LRRT without concurrent immunotherapy) groups. Recursive partitioning analysis (RPA) utilizing baseline and post-CT-IO factors was applied to stratify patients into low- or high-risk groups to evaluate the benefit of concurrent IO. Absolute lymphocyte count (ALC) was monitored during and up to 6 months post-LRRT. **Results:** A total of 238 patients were included (185 receiving concurrent IO and 53 without). In the IPTW-adjusted Kaplan-Meier analysis at the 12-month landmark, the addition of concurrent IO was associated with significantly inferior progression-free survival (PFS) (Hazard Ratio [HR]: 3.189; 95% CI, 1.352–7.524; p = 0.008). The "Sandwich" mode—comprising 4-6 cycles of induction CT-IO, followed by LRRT, and subsequent IO maintenance—yielded the optimal survival outcomes (HR: 0.288; 95% CI, 0.106–0.786; p = 0.015). An RPA model incorporating five prognostic factors (the number of metastatic lesions, pretreatment LDH level, post-CT-IO Epstein-Barr virus DNA, and radiological response post-CT-IO) stratified patients into two risk subgroups. Low-risk patients derived no clinical benefit from concurrent IO (p = 0.134), whereas high-risk patients exhibited significantly worse 12-month landmark adjusted PFS (p = 0.031). Notably, subgroup analysis showed that patients with persistent radiation-induced lymphocytopenia at 3 months post-RT demonstrated the most unfavorable survival outcomes after concurrent immunotherapy ($p < 0.001$). **Conclusions:** DmNPC patients receiving first-line CT-IO followed by LRRT did not benefit from concurrent immunotherapy during RT, particularly those identified as high-risk by the prognostic model and those with persistent lymphocytopenia at 3 months post-RT. Research Sponsor: None.

2623 **Poster Session**

Efficacy and safety of cadonilimab in patients with MSI-H/dMMR locally advanced or metastatic gastrointestinal malignancies: A real-world retrospective study. First Author: Xiaoyuan Sun, The Affiliated Hospital of Qingdao University, Gastrointestinal Oncology and Pancreatic Diseases Center, Qingdao, China

Background: Immunotherapies targeting PD-1 and CTLA-4 have emerged as promising therapeutic strategies for gastrointestinal malignancies (GIM), particularly those dMMR or MSI-H phenotypes. Cadonilimab, a novel bispecific antibody co-targeting PD-1 and CTLA-4, has showed potent anti-tumor effect across multiple cancer types. This real-world retrospective study systematically evaluated the efficacy and safety of cadonilimab in patients with MSI-H/dMMR locally advanced or metastatic GIM. **Methods:** This study retrospectively included patients with MSI-H/dMMR unresectable locally advanced or metastatic GIM who administered cadonilimab(6 mg/kg Q2W) since November 2022 in The Affiliated Hospital of Qingdao University. The primary endpoint was ORR as assessed by investigators per RECIST v1.1. Secondary endpoints included DCR, PFS, DoR, safety profile, and exploratory biomarker analysis (interleukins [IL-2, IL-6, IL-8, IL-10]) was performed on blood samples collected at baseline and before each treatment cycle. **Results:** As of November 7, 2025, a total of 21 patients were enrolled. The median follow-up duration was 19.4 months. The ORR was 76.19% and DCR was 100%. Median PFS and median DoR were not reached. The 12-month PFS rate was 74.9% (95% CI, 49.6%-88.8%) and 18-month PFS rate was 68.1% (95% CI, 41.6%-84.5%). Among 14 gastric cancer (GC) patients, ORR was 78.57% (5 CR, 6 PR), median PFS was not reached, 12-month PFS rate was 77.9% (95% CI, 58.6%-100%), and 18-month PFS rate was 68.2% (95% CI, 46.3%-100%). The ORR of GC treated in 1st line was 80%, 4 achieved CR (40%). Among 7 colorectal cancer (CRC) patients, ORR was 71.43% (2 CR, 3 PR), median PFS was not reached, 12-month PFS rate was 71.4% (95% CI, 49.6%-88.8%), and 18-month PFS rate was 71.4% (95% CI, 29.4%-91.9%); the ORR of 1st line treatment was 83.33%. By metastatic site: ORR was 85.71% in patients with peritoneal metastasis and 100% in those with pelvic metastasis. Notably, one patient achieved pCR after cadonilimab conversion therapy, and another patient receiving cadonilimab as fourth-line monotherapy achieved PFS of 25.4 months. As of data cutoff, 5 patients remained on treatment. Regarding safety, 33.33% of patients experienced grade 1-2 immune-related adverse events (irAEs), and 4.76% had grade ≥3 irAEs. No treatment discontinuation due to adverse events. Exploratory biomarker analysis showed that ORR was 90.91% in patients with high IL-2 expression, 91.67%,92.86% and 81.82% in patients with normal IL-6, IL-8 and IL-10 levels, respectively. **Conclusions:** Cadonilimab demonstrates potent and durable anti-tumor activity with a favorable safety profile in MSI-H/dMMR locally advanced or metastatic GIM. Additionally, interleukins may serve as potential predictive biomarkers for cadonilimab efficacy, providing insights for precision medicine in this patient population. Research Sponsor: None.

Intrathecal (IT) PD-1/CTLA-4 antibody combined with pemetrexed (PM) for leptomeningeal metastases (LM) from solid tumors: Preliminary results of two single-center phase I studies. First Author: Zhenyu Pan, Department of Radiation Oncology, Beijing Chest Hospital, Capital Medical University, Beijing, China

Background: IT PD-1 inhibitors, alone or combined with IT PM, have shown safety and feasibility in LM from solid tumors. Cadonilimab (AK104) and iparomlimab/tuvonralimab (QL1706) are novel bispecific PD-1/CTLA-4 antibody. Our preclinical animal studies demonstrated the safety of IT administration of these agents. This study evaluated the feasibility and potential clinical benefit of combing IT PD-1/CTLA-4 antibody with PM in patients with LM from solid tumors. **Methods:** Eligible patients had histologically confirmed solid tumors and positive CSF cytology. A rapid dose-escalation design was employed across three dose levels: AK104 at 15.625 mg, 31.25 mg and 62.5 mg; QL1706 at 25 mg, 37.5 mg and 50 mg. One patient was enrolled in each of the first two dose cohorts, while six were enrolled at the third dose cohort. The protocol would revert to a standard 3+3 design if any dose-limiting toxicities (DLT) occurred. IT PM was given at a fixed dose of 15 mg twice weekly for two weeks (induction), then weekly for four weeks (consolidation), followed by monthly maintenance until progression or death. IT PD-1/CTLA-4 antibody began at the fourth IT PM dose, administered every two weeks for six weeks, then monthly until progression or death. Continuation of previously administered systemic therapies was permitted during the study. **Results:** A total of 17 patients were enrolled (AK104: n=8; QL1706: n=9). Median age was 54 years (range 37–73); 13 were female. Primary tumors included lung adenocarcinoma (n=13) and breast cancer (n=4). 16 patients (94.1%) completed induction and consolidation therapy. No DLT occurred. Grade ≥3 adverse events (AEs) occurred in 64.7% (11/17) of patients. Specifically, grade ≥3 AEs attributed to IT PM were observed in 58.8% (10/17), primarily hematological toxicity (n=10), elevated hepatic aminotransferase (n=1) and fatigue (n=1). For IT PD-1/CTLA-4 antibody-related AEs, grade ≥3 occurred in 11.8% (2/17; rash n=1, diarrhea n=1), and grade 1-2 in 17.6% (3/17; rash n=3, fever n=1, diarrhea n=1). Clinical response rate was 41.2% (7/17) by RANO-LM criteria. Disease control rate was 82.4% (14/17). As of January 15, 2026, 8 patients had died, with 1 due to LM, 3 due to systemic progressive disease, and 4 due to non-cancer-related causes. Median follow-up time was 8.53 months (95%CI: 8.07-NA), and median overall survival was 8.53 months (95%CI: 6.3-NA). **Conclusions:** The study demonstrates the manageable safety and feasibility of IT PD-1/CTLA-4 antibody combined with PM, with no unexpected systemic or neurological toxicities observed. Preliminary results suggest potential clinical benefits, with a high clinical response rate and notable treatment responses even among those with severe conditions. ClinicalTrials.gov registration: NCT06762080/NCT06809530. Clinical trial information: NCT06809517/NCT06809530. Research Sponsor: Huizhou Science and Technology Innovation Team Project; 2023EQ050012; Huizhou Outstanding Young Scientific and Technological Talents Program; 2025EQ050018.

Evaluation of intravenous IPI201 in combination with anti–PD-1 therapy in a colorectal cancer mouse model. First Author: Brett Lanier, Isosceles Pharmaceuticals, Wilmington, NC

Background: Immune checkpoint inhibitors targeting PD-1 improve outcomes in colorectal cancer (CRC) but are limited by intrinsic and acquired resistance. Resorcinyl isoprenyl benzene derivatives have previously shown anti-tumor activity in multiple models, including remodeling of the tumor microenvironment (TME). IPI201 is a novel, synthetic resorcinyl isoprenyl benzene derivative administered intravenously. Here, we evaluated whether IPI201 combined with anti-PD-1 therapy alters tumor and immune outcomes in a murine model of CRC. **Methods:** MC38 colon tumors were implanted subcutaneously in mice and treated with vehicle, IPI201 (i.v.), anti-PD-1 (BE0156; i.p.), 5-fluorouracil (5-FU) (i.p.), or IPI201 plus anti-PD-1 at varying dose combinations once the implanted tumor reached a size of 75 mm^3. Change in tumor volume and subject survival were assessed over 30 days. Tumor necrosis was evaluated by blinded histopathology. Tumor gene expression was analyzed using NanoString nCounter immune-focused panels with pathway and network analyses comparing combination therapy to monotherapies and vehicle controls. **Results:** While IPI201 or anti-PD-1 monotherapy demonstrated limited activity, combination treatment produced enhanced anti-tumor effects. The optimal dose combination resulted in a 66% reduction in tumor growth compared with anti-PD-1 alone, with a significant treatment interaction (P=0.03). Combination therapy significantly improved survival relative to monotherapies and 5-FU (50% vs 0%, adjusted $P<0.02$), yielding the highest survival among treatment groups. Tumor necrosis scores were increased with combination therapy, with necrosis twofold higher than anti-PD-1 alone ($P<0.01$). Transcriptomic profiling revealed differential regulation of 771 genes across 51 biological pathways, including VEGF, EGFR, MAPK/ERK, and PI3K/Akt/mTOR signaling, as well as immune-associated pathways related to antigen presentation, cytotoxic lymphocyte activation, and myeloid cell recruitment. This transcriptional signature is consistent with a pro-immune, anti-tumor TME. **Conclusions:** IPI201 and PD-1 blockade combination improves survival, promotes tumor necrosis, and remodels the tumor microenvironment in a preclinical CRC model. These findings support further development of IPI201 as a combination immunotherapy strategy and provide a mechanistic rationale for evaluating resorcinyl isoprenyl benzene-based enhancers of checkpoint inhibition in CRC. 2626 **Poster Session**

Phase I/II study of LB1410, a bivalent TIM-3/PD-1 bispecific antibody, in combination with LB4330, a long-acting IL-10, in patients with advanced solid tumors. First Author: Jiajian Liu, L&L Bio Co., Ltd., Shanghai, China

Background: LB1410 is an anti-PD-1/TIM-3 bispecific antibody (BsAb) developed by L&L Bio Co., Ltd., Shanghai, China. In an ongoing phase I study in patients (pts) with advanced solid tumors (NCT05357651), LB1410 demonstrated an excellent safety profile (RPIID 20 mg/kg) and promising efficacy in various anti-PD-1-resistant solid tumors: ORR 9.1%; DCR 54.5%; n = 66 as of Jan 4, 2026. Antitumor activity was especially notable in anti-PD-1-resistant ccRCC (ORR 11.1%; DCR 77.8%; n = 9) and anti-PD-1-resistant CC (ORR 38.5%; DCR 69.2%; n = 13). LB4330 is a novel, long-acting IL-10 developed by L&L Bio Co., Ltd., Shanghai, China. It is generated by fusing IL-10 to a high-affinity anti-CLDN18.2 antibody and exhibits a significantly extended $T_{1/2}$ of 2.3 days. In a completed phase I study (NCT05707676), LB4330 effectively enhanced CD8+ T cell proliferation and activation in cancer pts and achieved a DCR of 36.4% (12/33) in pts with PDAC, CRC and other anti-PD-1-resistant tumors. Given their complementary mechanisms and potential to better enhance antitumor immune activity, a phase I/II study has been launched to evaluate LB1410 in combination with LB4330 in pts with advanced solid tumors. **Methods:** Eligible pts were ≥18 yrs old with ECOG PS 0-1. Pts received LB1410 at 15 or 20 mg/kg in combination with LB4330 at 0.2-0.4 mg/kg IV Q2W, with a maximum of 6 doses of LB4330. A 3+3 dose-escalation design was used to assess safety and tolerability. The selected doses of LB1410 at 15 or 20 m/kg plus LB4330 at 0.4 mg/kg were used for the efficacy expansion study in pts with anti-PD-1-resistant ccRCC and HCC. **Results:** As of Jan 14, 2026, 15 patients (1 CRC, 1 HCC, 3 NSCLC, 4 CC and 6 ccRCC) had been enrolled: median age 58.5 yrs (42-71 yrs); 57.1% male; 85.7% with prior anti-PD(L)1-based therapies. TRAEs occurred in 13 pts (92.9%), the most common (≥ 20%) being fever, platelet count decreased, pruritus, elevated ALT, elevated AST, elevated creatinine, cough, rash and anemia. Most TRAEs were related to the MOA of LB4330 and were manageable. Grade 3-4 TRAEs occurred in 5 pts (35.7%), including decreased platelet count in 2 pts and IRR, shock symptom and immune-mediated myocarditis in 1 pt each. No DLTs were observed. Among all pts with on-treatment scans, the overall ORR per RECIST 1.1 was 15.4% (2/13) with 2 confirmed PR ; DCR was 30.8% (4/13). Notably, the 5 pts with anti-PD-(L)1-refractory favorable-risk ccRCC showed an ORR of 40.0% and a DCR of 80.0%. 50% ccRCC pts with PR/SD (2/4) had been on treatment for nearly one year or longer. **Conclusions:** The combination of LB1410 and LB4330 exhibited a manageable safety profile consistent with that observed with each monotherapy. Clinical data in pts with favorable-risk ccRCC support the characteristics and efficacy of LB4330 as an immune-enhancing agent. Efficacy expansion studies are ongoing. Clinical trial information: NCT06468358. Research Sponsor: L&L Bio Co., Ltd., Shanghai, China.

2627 **Poster Session**

Low-dose intestinal irradiation to enhance the efficacy and prognosis of PD-1 blockade in metastatic non-small cell lung cancer. First Author: Baiyang Huang, Department of Radiation Oncology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, Shandong, China

Background: Intestinal low-dose irradiation (ILDR) has been shown to enhance the efficacy of immunotherapy in advanced solid tumors by modulating the gut microbiota and metabolism. However, its role in metastatic non-small cell lung cancer (mNSCLC), particularly in the first-line treatment setting, remains unclear. Therefore, this study investigated the impact of intestinal radiation dose on the efficacy and prognosis of programmed cell death protein 1 (PD-1) blockade in patients with mNSCLC. **Methods:** This multicenter retrospective and prospective study included patients with mNSCLC who received first- or second-line PD-1 inhibitors combined with abdominopelvic radiotherapy between 2018 and 2025. Patients were stratified into three groups according to the mean intestinal radiation dose: <1 Gy, 1–3 Gy, and >3 Gy, and treatment outcomes were compared among groups. In addition, blood and fecal samples prospectively collected were subjected to multi-omics analyses. **Results:** A total of 301 patients were included in the retrospective analysis, among whom 105 patients (34.9%) had a small intestinal mean radiation dose (SIMRD) <1 Gy, and 84 patients (27.9%) had a SIMRD of 1–3 Gy. Overall, 183 patients (60.8%) received first-line PD-1 blockade, and 118 patients (39.2%) received second-line treatment. The median follow-up time was 27.2 months. The results showed that patients with a SIMRD of 1–3 Gy achieved the highest objective response rate (21.0% vs. 48.8% vs. 6.3%). Compared with the <1 Gy and >3 Gy groups, the 1–3 Gy group also demonstrated significantly prolonged progression-free survival (PFS, 10.2 months) and overall survival (OS, 23.7 months) ($P < 0.01$), with consistent findings across all subgroup analyses. Compared with the 1–3 Gy group, SIMRD >3 Gy (HR = 4.96, $P < 0.001$) and SIMRD <1 Gy (HR = 1.90, $P < 0.001$) were both independent predictors of worse OS. Thirty patients who recevied first-line PD-1 inhibitors combined with abdominopelvic radiotherapy were included in the prospective analyses. With a median follow-up of 17.5 months, patients with a SIMRD of 1–3 Gy achieved the best disease control rate (1-3 Gy vs. <1 Gy vs. >3 Gy: 90.0% vs. 63.7% vs. 33.3%; P = 0.041) and the longest median PFS (1-3 Gy vs. <1 Gy vs. >3 Gy: not reached vs. 9.3 months vs. 5.8 months; P = 0.120). Multi-omics analyses revealed that responders were enriched in *Bacillota*, *Clostridia*, and indole-derived metabolites, particularly indole-3-carboxylic acid. Moreover, patients in the 1–3 Gy group exhibited increased circulating macrophage inflammatory protein-3α levels and a reduced proportion of $\alpha4\beta7^+$ regulatory T cells. **Conclusions:** ILDR influences the efficacy of PD-1 inhibitor therapy in patients with mNSCLC, with the most pronounced benefit observed when SIMRD is maintained within the 1–3 Gy range. This effect may be mediated through modulation of the gut microbiota–metabolite–immune axis. Personalized N-of-1 combinations based on molecular profiles in advanced malignancies: Immunotherapy group analysis of the I-PREDICT N-of-1 precision oncology study. First Author: Yuji Uehara, Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan

Background: While current precision oncology typically targets a single biomarker, most cancers have multiple pathogenic alterations that often differ from patient to patient. We evaluated whether individualized, N-of-1 biomarker-based combinations that included immune checkpoint inhibitors (ICIs) would improve outcomes in patients (pts) with advanced cancers. **Methods:** In the I-PREDICT prospective trial (NCT02534675), 70 pts with advanced poor-prognosis cancers received ICI-based regimens. Personalized combinations were based on tissue/ctDNA next-generation sequencing (NGS) and Molecular Tumor Board review. An "i-Matching Score" was developed using TMB ≥16 mut/Mb—selected because analysis showed it was a more robust outcome predictor than TMB ≥10 or continuous TMB (though both correlated with some outcome parameters)—alongside scores reflecting the matching of other targeted therapies (TT) to tumor alterations. Regimens used individualized dose reductions and intra-patient dose titration for safety. **Results:** Tumors harbored a median of five pathogenic alterations (range, 1–18); 97% of pts had unique molecular profiles. To optimize biomarker-matching, pts received 48 distinct therapy regimens, many previously unstudied; for the first-in-human (FIH) combinations, initial doses were lowered, and intra-patient dose modifications were made for tolerance. Regimens included ICI monotherapy (20%), ICI + TT (61%), and others. Mean initial dose was 79.5% of the FDA-approved dose; 26% of pts had dose adjustments (6% increase; 20% decrease). Initial doses were lower for multi-drug regimens (P=0.002), ICI+TT ($P<0.001$), and FIH regimens (P=0.005) vs. established regimens. Grade ≥3 treatment-related serious adverse events (SAEs) occurred in 14% of 70 pts; notably, the SAE rate for ICI monotherapy (established safety profile) was 15%, and no combination subgroup significantly exceeded this rate. FIH regimens and high i-Matching groups (>50% vs. ≤50%) trended towards fewer SAEs (P=0.06/0.08). TMB ≥16 independently predicted improved disease control rate (DCR; SD ≥6mo/PR/CR), PFS, and OS (P=0.006/0.001/0.016); i-Matching Score >50% vs. ≤50% significantly correlated with higher DCR (74% vs 27%, $P<0.001$), longer PFS (10.4 vs 3.8 mo, $P<0.001$) and OS (19.1 vs 9.1 mo, P=0.016). In pts receiving ICI+TT (n=51), the i-Matching Score outperformed TMB as an outcome predictor. **Conclusions:** Individualized, N-of-1 ICI-based combinations, molecularly matched to complex genomic profiles, can be safely given with initial dose reduction and intra-patient dose modification. Higher TMB and higher degrees of biomarker matching (i-Matching Score) correlated with improved outcomes, with the latter performing best in pts receiving ICI+TT combinations. This molecularly guided multi-agent therapy paradigm warrants further study. Clinical trial information: NCT02534675. Phase 1 dose escalation of CTX-8371, a novel PD-1×PD-L1 bispecific antibody, in patients with advanced malignancies post checkpoint inhibition. First Author: Judy S. Wang, Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, FL

Background: CTX-8371 is a novel bispecific antibody targeting both programmed cell death 1 (PD-1) and programmed cell death ligand 1 (PD-L1). In addition to potent PD-1 and PD-L1 blockade, CTX-8371 uniquely enables CD80-CD28 engagement and facilitates the cleavage of PD-1 from the surface of activated T-cells. Preclinically, CTX-8371 exhibited greater potency than singular blockade with either anti-PD1 or anti-PD-L1 alone. **Methods:** In this first-in-human study (NCT06150664) with a 3+3 dose-escalation design, patients (pts) with metastatic melanoma, non-small cell lung cancer (NSCLC), head and neck squamous cell carcinoma (HNSCC), Hodgkin lymphoma (HL), and triple-negative breast cancer (TNBC) in whom standard treatments including prior immune checkpoint inhibitors (ICI) had failed, were eligible. CTX-8371 was administered intravenously every two weeks at 5 dose levels ranging from 0.1 to 10.0 mg/kg. The primary objectives were to evaluate the safety and tolerability of CTX-8371 and determine doses to be evaluated in expansion. Secondary objectives included assessment of anti-tumor activity, pharmacokinetics, pharmacodynamics, and immunogenicity of CTX-8371. **Results:** Between 15 Apr 2024 and 12 Aug 2025, 17 pts were enrolled; 15 pts completed the dose-limiting toxicity (DLT) period and had post-baseline imaging: NSCLC n=7, melanoma n=3, HNSCC n=2, TNBC n=2, HL n=1. All 15 pts had received a minimum of 2 prior therapies including checkpoint inhibitors. Median duration on study was 9.8 months; CTX-8371 treatment is ongoing in 3 pts. CTX-8371 was well tolerated with no DLTs. The maximum tolerated dose (MTD) was not reached. All treatment-related adverse events (AEs) were Grade 1/2, except one Grade 3 AE of asymptomatic lipase increase which resulted in the only dose interruption. There were no dose reductions. Dose-dependent increases in CTX-8371 serum concentrations (AUC and Cmax) were observed. In the 15 pts with post-baseline imaging, the overall response rate (ORR) was 20% (one pt each with NSCLC [irPR], TNBC and HL) and the disease control rate (DCR) was 60%. The responses were 2.3 months NSCLC; 6.4+ months TNBC; 3.6+ months HL with greater depth and longer durability at the recommended doses for further study ($\geq$ 3 mg/kg). The two ongoing responders are in pts treated at 3 mg/kg (TNBC: $>$90% reduction in overall tumor volume) and 10 mg/kg (HL: metabolic partial response). **Conclusions:** CTX-8371, a novel bispecific antibody targeting both PD-1 and PD-L1, was well tolerated and demonstrated promising clinical activity as a monotherapy in advanced pts resistant to prior ICI. Dose expansion in pts with NSCLC and TNBC in 2 dosing cohorts (3 and 10 mg/kg) is underway. Future development in treatment refractory HL is planned. Clinical trial information: NCT06150664. Clinical efficacy of tislelizumab in combination with gemcitabine and nab-paclitaxel and chemoresistance analysis in borderline resectable pancreatic cancer: A prospective pilot study. First Author: Yonggang He, Department of Hepatobiliary Surgery, the Second Affiliated Hospital of Army Medical University, Chongqing, China

Background: Neoadjuvant therapy has been demonstrated to improve the survival outcomes of patients with borderline resectable pancreatic cancer (BRPC). While neoadjuvant therapy is increasingly utilized, exploring novel combination strategies, such as immunotherapy plus chemotherapy, is essential to further enhance surgical resectability and survival outcomes. This study investigated the clinical feasibility of tislelizumab in combination with gemcitabine and nab-paclitaxel for BRPC in a neoadjuvant setting. **Methods:** In this prospective study, patients diagnosed with BRPC were enrolled. Preoperatively, intravenous injection of tislelizumab (200 mg per time, Q3W) was used for 3 cycles, in combination with gemcitabine (1 000 mg/m^2, d1, d8) and nab-paclitaxel (125 mg/m^2, d1, d8). Postoperatively, this regimen continued to be used. The primary endpoints were the margin-negative (R0) resection rate and treatment-related adverse events (TRAEs). Exploratory objectives were resistance to this neoadjuvant regimen. **Results:** Totally 30 patients were enrolled in this study, among whom 80.0% (24/30) completed neoadjuvant therapy and underwent surgical resection. R0 resection was achieved in 80.0% of the patients (24/30) and in 100.00% of the patients with surgical resection (24/24). Most patients experienced grade I-II TRAEs, and no serious TRAEs occurred. Through the quantitative proteomics and machine learning algorithms for differentially expressed proteins, NT5DC2, FAM3D, CXCL5 and TMT1B were identified to play crucial roles in resistance to the neoadjuvant regimen in pancreatic cancer. **Conclusions:** Neoadjuvant therapy with tislelizumab plus gemcitabine and nab-paclitaxel demonstrated clinical feasibility and encouraging antitumor activity in BRPC patients, with a favorable safety profile. NT5DC2, FAM3D, CXCL5 and TMT1B may be the biomarkers for preoperative drug resistance in pancreatic cancer. Clinical trial information: ChiCTR2200063680. Clinical trial information: ChiCTR2200063680. A phase 2 study of fruquintinib combined with sintilimab and chidamide in refractory MSS metastatic colorectal cancer: Preliminary efficacy and safety. First Author: Chang Wang, The First Hospital of Jilin University, Changchun, China

Background: Microsatellite stable (MSS) metastatic colorectal cancer (mCRC) has limited response to immune checkpoint inhibitors. Preliminary evidence from preclinical studies and the CAPability-01 trial suggest that combining anti-angiogenic therapy with epigenetic drugs such as histone deacetylase inhibitors can favorably remodel the tumor immune microenvironment and enhance the efficacy of PD-1 immune checkpoint blockade for advanced MSS-type mCRC. This study evaluates the efficacy and safety of the triple combination of fruquintinib, sintilimab, and chidamidein patients with refractory MSS mCRC. **Methods:** This is a single-arm, open-label phase 2 study. Eligible patients had histologically confirmed MSS-type mCRC, disease progression after $\geq$2 prior lines of therapy, $\geq$1 measurable lesion (RECIST v1.1), and ECOG 0–1. Patients received fruquintinib (5 mg orally on days 1–14, Q3w), sintilimab (200 mg IV on day 1, Q3w), and chidamide (30 mg orally twice weekly). The primary endpoint was mPFS. Secondary endpoints included ORR, DCR, mOS, DOR and safety. Tumor assessments were performed every 9 weeks. With a statistical hypothesis of improving the median PFS from 3.7 (historical control) to 6.0 m, a sample size of 46 patients was planned. **Results:** From January to December 2025, a total of 9 patients were enrolled. The median age was 60.0 years (39–72). All patients had MSS-type tumors, with a median of 2 prior lines of therapy (range: 2–4). Preliminary efficacy analysis showed that 4 patients achieved PR and 2 achieved SD, resulting in an ORR rate of 44.4% and a DCR rate of 66.7%. Given the limited sample size and relatively short follow-up of 9.1m at this preliminary analysis, mPFS and mOS were not yet reached. Treatment was generally tolerable. TRAEs of any grade occurred in all 9 patients. The most common TRAEs included hematological toxicities such as thrombocytopenia (66.7%), neutropenia (44.4%), and leukopenia (33.3%); hepatic laboratory abnormalities including elevated ALT 33.3%), and elevated AST (33.3%); as well as proteinuria (66.7%), hyperlipidemia (55.6%), increased blood creatine kinase (55.6%), and fatigue (1/9 with Grade 3). Grade $\geq$3 TRAEs were observed in 5 patients (55.6%), including Grade 3 neutropenia (2 patients), fatigue (1 patient), cutaneous adverse reactions (1 patient), and cholecystitis (1 patient). No treatment-related deaths occurred. **Conclusions:** Preliminary results indicate that the triple therapy of fruquintinib, sintilimab, and chidamide demonstrates promising response rate, disease control and a manageable safety profile in patients with refractory MSS-type mCRC. This combination strategy represents a potential therapeutic option for this population, who currently have limited treatments available. Further follow-up with a larger sample size and longer duration is needed to confirm its survival benefit. Clinical trial information: NCT06979908. Research Sponsor: None.

2632 **Poster Session**

A phase II study to evaluate the safety and efficacy of BB-1701 in combination with sintilimab in patients with HER2 expression or mutation in locally advanced/metastatic breast cancer or NSCLC. First Author: Anwen Xiong, Department of Oncology, Shanghai East Hospital, Tongji University, Shanghai, China

Background: BB-1701, a HER2-targeting antibody-drug conjugate (ADC) containing eribulin, has demonstrated promising antitumor activity in the clinical studies in breast cancer (BC) patients with HER2 low expression and non-small cell lung cancer (NSCLC) patients with HER2 mutation. Currently, there are no approved treatment options of ADC in combination with anti-PD-1 antibody for metastatic BC patients with HER2 low expression and NSCLC patients with HER2 mutation. We report the preliminary efficacy and safety results from the ongoing phase 2 study (including dose escalation and dose expansion) of BB-1701 in combination with Sintilimab (an anti-PD-1 antibody) in advanced or metastatic BC patients with HER2 low expression and NSCLC patients with HER2 mutation. **Methods:** Patients enrolled were $\geq$18 years of age; had confirmed locally advanced/metastatic HER2 low-expressing BC or HER2 mutated NSCLC, an ECOG PS $<$2 and measurable lesion(s) (per RECIST v1.1); and disease progression after $\geq$1 lines of prior standard therapies. HER2 expression was confirmed by IHC or NGS/PCR before patient enrollment. BB-1701 was administered at 1.2 mg/kg Q3W or 1.6 mg/kg Q3W, and sintilimab is administered at 200 mg Q3W. **Results:** As of 26 January 2026, a total of 12 patients with HER2 low-expressing BC or HER2 mutated NSCLC have been enrolled and treated, 6 patients at each dose level of BB-1701 during dose escalation. Median age is 63 years, 91.7%/8.3% patients were female/male, and 16.7%/83.3% patients have ECOG PS 0/1. The median number of prior systemic therapy lines was 2.0/1.0 for BC and NSCLC. All patients experienced at least one treatment-emergent adverse events (TEAEs). The most common ($\geq$20%) reported all grade TEAEs are alanine aminotransferase increased, aspartate aminotransferase increased, γ-glutamyltransferase increased, hypercholesterolemia, peripheral neuropathy, anemia and Urinary tract infection. Three grade 3 TEAEs are γ-glutamyltransferase increased, pneumonia and open globe injury. There has been no grade 4 or grade 5 events as of data cut-off date. One treatment emergent serious adverse event is open globe injury. All patients were evaluable for efficacy. Among 5 BC patients, 4 patients achieved partial response (PR) with disease control rate (DCR) of 80.0%. Among 7 NSCLC patients, 2 patients achieved PR and 2 patients had stable disease (SD) with DCR of 57.1%. Details of data will be presented at the ASCO meeting. **Conclusions:** BB-1701 in combination with Sintilimab shows encouraging antitumor activity and a manageable safety profile in HER2 low-expressing BC patients and HER2 mutated NSCLC patients. The further dose expansion study is guaranteed based on the preliminary data from dose escalation study. Clinical trial information: CTR20241422. Research Sponsor: None.

2633 Poster Session

Outcomes of patients with rare cancers treated with combination immune checkpoint inhibitors with and without lung and/or liver metastases (NCI/SWOG S1609). First Author: Megan Othus, Fred Hutch Cancer Center, Seattle, WA

Background: Limited prior retrospective data, primarily among patients with lung cancer, liver cancer, and melanoma, has indicated that liver metastases are associated with poorer outcomes with chemotherapy, targeted agents, and checkpoint inhibitor therapy. We used a unique clinical trial resource to evaluate whether liver and/or lung metastases were associated with outcomes among patients with rare tumors treated with combination anti-PD-1 and anti-CTLA-4 therapy. **Methods:** The basket trial, SWOG trial S1609 (NCT02834013, DART trial), treated 655 eligible patients without lung or liver primary cancers. Associations with progression-free and overall survival were evaluated with Cox regression models; multivariable models controlled for age at trial registration, sex, performance status, race, ethnicity, primary tumor organ. Associations with clinical benefit rate (confirmed complete and partial response or stable disease for six months or longer) and treatment-related adverse events were evaluated using Fisher's exact test. **Results:** There was no significant difference in rates of grade 3 or higher treatment-related adverse events across the groups. Participants with liver metastases, with or without lung metastases, had a lower likelihood of experiencing clinical benefit (11% and 18%, respectively) compared to participants with lung but not liver metastases or participants with neither lung nor liver metastases (26% and 30%, respectively, p=0.003). On multivariable analysis, both lung and liver metastases were associated with shorter progression-free and overall survival compared to presence of neither liver nor lung metastases. **Conclusions:** In a diverse cohort of participants with advanced rare tumors treated with combination anti-CTLA-4 and anti-PD-1 therapy, we found that both lung and liver metastases were associated with shorter progression-free and overall survival. Research Sponsor: US National Cancer Institute; U10CA180888 and U10CA180819.

Prior CTLA-4 blockade as associated with a hyperactive immunosuppressive signature and limited response to subsequent immunotherapy in melanoma. First Author: Omid Hamid, The Angeles Clinic and Research Institute, A Cedars-Sinai Affiliate, Los Angeles, CA

Background: Checkpoint blockade achieves durable long term responses in about 30-50% of patients with malignant melanoma (MM). However, a substantial proportion of patients either fail to respond or develop resistance after initial response. As a result, many MM patients undergo multiple sequential immunotherapeutic treatments in an attempt to achieve clinical benefit. However, the effects of repeated rounds of immunotherapy on the immune system remain poorly understood. We herein report that prior anti-CTLA-4 blockade within 12 months of analysis associated with a hyperactive immunosuppressive immune signature involving IL-6, in 24 patients with anti-PD-1 refractory metastatic MM enrolled in a Phase I/II trial. **Methods:** The patients received continued checkpoint inhibition with an anti-PD-L1 antibody in combination with an immunostimulatory gene therapy based on replication-competent adenovirus targeting the CD40 and 4-1BB pathways (LOKON003, NCT04123470). Using unsupervised clustering, plasma biomarker profiles at baseline and post treatment initiation was evaluated and correlated to clinical parameters. **Results:** Two plasma protein profiles were identified at baseline among enrolled patients and one of those included immunosuppressive biomarkers. While patients with this hyperactive immunosuppressive signature (n=8) at baseline experienced a median overall survival (mOS) of 4.0 months, patients without this baseline signature (n=15) had a mOS of 28.1 months. The hyperactive immunosuppressive signature was not related to M1 status, sex, age, or number of prior treatments, but prior anti-CTLA-4 treatment within a year of enrollment was more prevalent in patients with this signature. If dividing the patients only based on receiving anti-CTLA-4 therapy within 12 months (n=10) versus later or not at all (n=14), mOS was 5.3 and 30.7 months, respectively. Patients that had received recent anti-CTLA-4 treatment, presented with a plasma protein signature resembling the hyperactive immunosuppressive signature with IL-6 as a central node among the upregulated proteins. Patients who did not receive anti-CTLA-4 blockade during the past 12 months responded to the combination of the immunostimulatory gene therapy and continued checkpoint blockade with upregulation of biomarkers associated with T cell activation and cell killing capacity, which may have supported the better survival outcome in this patient group. **Conclusions:** The findings highlight the need for further clinical evaluation of the consequences of repeated immunotherapeutic treatments, IL-6 inhibition in this population, and consideration for a wash-out period from further immunotherapy to allow for immune system recovery post anti-CTLA-4 treatment. Clinical trial information: NCT04123470. Research Sponsor: The Swedish Cancer Society; The Swedish Research Council; Lokon Pharma.

2635 Poster Session

Phase IIa study of tosposertib, a dual TGFβRI and VEGFR2 inhibitor, in combination with pembrolizumab in recurrent and/or metastatic head and neck squamous cell carcinoma (R/M HNSCC). First Author: Hye Ryun Kim, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: Tosposertib (TU2218) is a highly potent dual inhibitor of the transforming growth factor-β type I receptor (TGFβRI/ALK5) and vascular endothelial growth factor receptor 2 (VEGFR2), designed to simultaneously target immunosuppressive tumor microenvironment signaling and angiogenesis. This open-label, multicenter, non-randomized phase IIa trial evaluated the efficacy and safety of tosposertib in combination with pembrolizumab in patients with R/M HNSCC (NCT05784688). **Methods:** Eligible patients included anti–PD-(L)1–naïve patients with PD-L1 combined positive score (CPS) ≥1. Tosposertib (97.5 mg twice daily; 2 weeks on/1 week off) was administered orally in combination with pembrolizumab (200 mg intravenously every 3 weeks). **Results:** As of December 31, 2025, 29 patients (median age, 61 years; 76% male) had been enrolled, with a median follow-up duration of 6.0 months (range, 8–401 days). Primary tumor sites included the oral cavity (n=11, 37.9%), oropharynx (n=6, 20.7%), larynx (n=3, 10.3%), and nasal/paranasal regions (n=3, 10.3%). HPV positivity was observed in 13.8% (4/29) of patients. Among 26 efficacy-evaluable patients, responses were assessed by treatment line. In the first-line setting, 9 of 12 patients achieved an objective response (ORR, 75.0%), including 1 confirmed complete response (CR) and 8 partial responses (PRs; 6 confirmed, 2 unconfirmed). Among the 14 patients who had received at least one prior systemic therapy, the ORR was 42.9%, with 1 confirmed CR and 5 confirmed PRs. A numerically higher ORR was observed in patients with PD-L1 CPS ≥20 compared with those with CPS 1–10 (66.7% vs 52.9%). The most frequent any-grade treatment-emergent adverse events (TEAEs), (≥20%) [and ≥ Gr3 TEAEs], were rash (48.3% [20.7%]), mucosal inflammation (34.5% [13.8%]), pruritus (27.6% [3.4%]), weight loss (27.6% [0%]), and elevations in aspartate aminotransferase (AST; 20.7% [3.4%]) or alanine aminotransferase (ALT; 20.7% [3.4%]). Discontinuations due to TEAEs occurred in three patients. No treatment-related deaths were reported. **Conclusions:** Tosposertib in combination with pembrolizumab demonstrated a manageable safety profile and encouraging antitumor activity in patients with R/M HNSCC, with particularly robust efficacy observed in the first-line setting and a favorable trend in PD-L1–high tumors. Clinical trial information: NCT05784688. Research Sponsor: TiumBio Co., Ltd.

Association of mRNA COVID-19 vaccination near immune checkpoint inhibitor initiation with outcomes: A real-world analysis. First Author: Changchuan Jiang, UT Southwestern Medical Center, Dallas, TX

Background: Prior study showed mRNA COVID-19 vaccines can activate innate and adaptive immune pathways and have been hypothesized to "prime" anti-tumor immunity via increased tumor PD-L1 expression when administered near immune checkpoint inhibitor (ICI) initiation. We performed a real-world validation to evaluate the association between COVID-19 vaccination around ICI initiation and outcomes among patients with 4 advanced/metastatic solid tumors. **Methods:** Using ConcertAI Patient360 (US-based, deidentified, human-abstracted oncology EHR linked to medical/pharmacy claims and third-party mortality), we identified adults (≥18 years at diagnosis) with advanced/metastatic bladder cancer, melanoma, non-small cell lung cancer (NSCLC), or renal cell carcinoma (RCC) who initiated an ICI between Jan 2021 and Mar 2024. Exposure was receipt of ≥1 mRNA COVID-19 vaccine within 100 days of ICI initiation. Exposed patients were propensity score–matched 1:1 to unexposed patients on demographics (age, sex, race, ethnicity) and clinical factors (baseline steroid use, ICI initiation year, Charlson Comorbidity Index, ECOG performance status, BMI, and tumor type). Real-world OS (rwOS) and real-world PFS (rwPFS) were estimated by Kaplan-Meier; hazard ratios (HRs) were estimated using univariate Cox models (post-match) and multivariable Cox models (residual confounding sensitivity), overall and by tumor type. **Results:** Among 7085 eligible patients, 1,513 were vaccinated around ICI initiation. After matching, 3,018 patients (1,509 per group) had evaluable time-to-event data and were included in Kaplan-Meier and Cox analyses (tumor mix: NSCLC 73.6%, RCC 11.7%, bladder 8.5%, melanoma 6.3%). Overall, vaccination was associated with improved rwOS and rwPFS: median rwOS 19.52 vs 15.31 months ($p<0.001$) and median rwPFS 7.95 vs 6.37 months (p=0.002). Univariate Cox models favored vaccination for rwOS (HR 0.82; 95% CI 0.75–0.90; $p<0.001$) and rwPFS (HR 0.88; 95% CI 0.81–0.95; p=0.002), with consistent findings in multivariable models (rwOS HR 0.81; 95% CI 0.74–0.89; $p<0.001$; rwPFS HR 0.87; 95% CI 0.80–0.95; p=0.001). Twelve-month rwOS was 64.87% vs 54.45% (vaccinated vs unvaccinated). By tumor type, univariate (post-match) associations were directionally favorable and strongest in NSCLC (rwOS HR 0.79; 95% CI 0.71–0.87; $p<0.001$; rwPFS HR 0.85; 95% CI 0.77–0.93; $p<0.001$). Similar, non-significant trends were observed in smaller bladder and RCC cohorts; melanoma showed no association with rwOS. **Conclusions:** In this large propensity score–matched real-world cohort of ICI-treated patients, COVID-19 vaccination within 100 days of ICI initiation was associated with significant improvements in rwOS and rwPFS, particularly in NSCLC. Prospective validation and randomized clinical trials are warranted to confirm these findings. Research Sponsor: UTSW.

Impact of COVID-19 mRNA vaccines on survival outcomes in patients with solid tumors receiving immunotherapy: A large-scale retrospective study. First Author: Bayan Khasawneh, Department of Medicine, Houston Methodist Hospital, Houston, TX

Background: Immune checkpoint inhibitors (ICIs) became the cornerstone in the treatment of solid tumors. While personalized cancer vaccines have yet to overcome complex scalability and manufacturing challenges, preclinical data suggests SARS-CoV-2 mRNA vaccines prime innate immunity, potentially enhancing ICI efficacy. A study by Grippin et al. evaluated the use of mRNA vaccine in NSCLC and melanoma patients receiving ICI and showed improved median and three-year overall survival (OS). We conducted a multicenter retrospective study to determine if this survival benefit extends across a broader range of ICI-treated solid tumors. **Methods:** Using the TriNetX global network, we identified adults (≥18) with solid tumors (NSCLC, melanoma, colorectal, hepatobiliary, gallbladder, gastric, bladder, pancreatic, renal, breast, head and neck, and esophageal) who received ICI treatment. The experimental group received SARS-CoV-2 mRNA vaccine within 100 days of ICI initiation; controls received no mRNA vaccine from 100 days pre-index through follow-up. Exclusion criteria: COVID-19 infection within 100 days and through the follow-up period. 1:1 propensity score matching (PSM) balanced demographics and comorbidities. Primary endpoint was median OS, including tumor-specific subgroup analyses. Survival was assessed via Kaplan-Meier and log-rank tests. **Results:** After PSM, we had 15,374 matched patients (7,687 per group). Vaccination within 100 days of ICI was associated with improved median OS (1,421 vs 667 days; HR 0.63; 95% CI 0.60-0.66; p<.001). Benefit was observed in 10 of 12 tumor types. Strongest effects were in NSCLC (n=7,350; HR 0.64), melanoma (n=2,684; HR 0.61; landmark survival 62.1% vs 50.3%), hepatobiliary (n=1,428; HR 0.64), colorectal (n=1,068; HR 0.67), gastric (n=792; HR 0.68), bladder (n=1,398; HR 0.63), pancreatic (n=240; HR 0.65), renal (n=1,996; HR 0.64), head and neck (n=964; HR 0.68), and esophageal (n=828; HR 0.63). No significant benefit was seen in breast (n=1,412; HR 0.85) or gallbladder cancer (n=58; HR 0.88). **Conclusions:** SARS-CoV-2 mRNA vaccination within 100 days of ICI therapy was associated with improved survival across solid tumors. These results suggest off-the-shelf RNA therapeutics may be scalable, cost-effective enhancers of cancer immunotherapy. Prospective studies are needed to confirm these findings and define the impact of universal mRNA strategies. Research Sponsor: None.

Distinct T-cell subsets as drivers of response to different neoadjuvant treatments in esophageal squamous cell carcinoma. First Author: Xin-yun Song, Department of Radiation Oncology, Shanghai Chest Hospital School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Background: The optimal integration of immunotherapy with chemoradiotherapy (CRT) in the neoadjuvant treatment of esophageal squamous cell carcinoma (ESCC) remains unclear, largely due to limited mechanistic insight into immune determinants of response. **Methods:** we performed paired single-cell RNA and TCR sequencing of ESCC tumor samples collected before and after treatment across three neoadjuvant modalities—immunochemotherapy (NICT), chemoradiotherapy (NCRT), and immunochemoradiotherapy (NICRT)—to dissect intratumoral $CD8^+$ T cell dynamics. **Results:** We identified two distinct immune response programs. In NICT responders, pre-existing immunoresponsive $CXCL13^+PD\text{-}1^+CD8^+$ T cells underwent clonal expansion and transcriptional reprogramming into a less exhausted yet CXCL13+ progenitor-like state (CD8Tex_CXCR4), accompanied by the formation of tertiary lymphoid structures. Conversely, CRT responders exhibited depletion of the subset of $CXCL13^+$ $CD8^+$ T cells and enrichment of PD-1^- cytotoxic CD8Teff_NIBAN1 cells, which originated from the peripheral blood and were characterized by robust clonal expansion, high effector gene expression, and association with tumor regression. We validated the association of these two T cell subsets with distinct neoadjuvant modalities and treatment responses using public datasets and independent prospective cohorts encompassing NICT, NICRT, and NCRT. Mechanistically, conventional radiotherapy suppressed PD-1^+ T cell expansion—even in the presence of ICB—while a sequential strategy of induction ICB followed by delayed radiotherapy preserved the process of clonal expansion in exhausted T cell populations and achieved superior tumor control in vivo. **Conclusions:** These findings reveal divergent $CD8^+$ T cell–mediated immune programs driving response to neoadjuvant therapies in ESCC and identify CD8Teff_NIBAN1 as a key effector population following CRT. Our study provides mechanistic insight into ICB–radiotherapy interactions and supports the rational design of temporally optimized combination strategies in solid tumors. Research Sponsor: None.

Phase I study of LB1410, a bivalent TIM-3/PD-1 bispecific antibody, in patients with advanced solid tumors. First Author: Jiajian Liu, L&L Bio Co., Ltd., Shanghai, China

Background: LB1410 is a recombinant humanized anti-PD-1/TIM-3 bispecific antibody (BsAb) developed by L&L Bio Co., Ltd, Shanghai, China for patients (pts) resistant/refractory (R/R) to anti-PD-(L)1 therapies. Pre-clinical studies revealed superior T cell and DC activity and *in vivo* antitumor efficacy compared to the combined use of TIM-3 and PD-1 monoclonal antibodies. This ongoing open-label phase I trial evaluates LB1410 monotherapy in pts with advanced solid tumors. **Methods:** Eligible pts were ≥18 yrs old with ECOG PS 0-1. Dose ranged from 0.001 to 20 mg/kg IV Q2W or 2000 mg/kg IV Q3W in an accelerated titration or a traditional 3+3 design. The RPIID of 20 mg/kg was used for efficacy expansion in pts with advanced clear cell renal cell carcinoma (ccRCC), cervical cancer (CC) and hepatocellular carcinoma (HCC). The primary objective was safety, including dose-limiting toxicities (DLTs); secondary objectives included efficacy, pharmacokinetics (PK) and immunogenicity. **Results:** As of Jan 4, 2026, 94 pts were enrolled: median age 59 yrs (31-73 yrs); 64.9% male; 84.0% ECOG PS 1. Tumor types included NSCLC (26.6%), CRC (21.3%, all non-MSI-H), CC (14.9%), ccRCC (11.7%), HCC (9.6%) and others (16.0%). 77 pts (81.9%) had received ≥ 2 prior lines of therapy. 98.6% non-CRC pts (73/74) were R/R to anti-PD-(L)1 therapies. 72 pts (76.6%) experienced TRAEs. The most common TRAEs (≥ 10%) included anemia (25.5%), proteinuria (11.7%), elevated ALT (11.7%), elevated AST (11.7%) and elevated lactate dehydrogenase (10.6%). Only 10 pts (10.6%) experienced Grade 3-4 TRAEs, most frequently hypertension (4.3%) and hypokalemia (2.1%). Only 1 hypertension and 1 elevated GGT in 1 pt were Grade 4. Serious TRAEs occurred in 3 pts (3.2%). No DLTs were observed. Among pts with available on-treatment scans, the overall ORR per RECIST 1.1 was 7.1% (6/85) with 5 confirmed PRs and 1 confirmed CR; the DCR was 48.2% (41/85). Notably, among CC pts previously treated with anti-PD-(L)1 therapies, there were 4 confirmed PRs and 1 confirmed CR: ORR 38.5% (5/13); DCR 69.2% (9/13); mPFS 7.5 months. 5 pts with CR/PR/SD remained on treatment (max. 16 treatment cycles; max. follow-up 14.4 months). The CR patient had received 5 prior lines of therapy, including PD-1/CTLA-4 BsAb. In anti-PD-1-resistant ccRCC, LB1410 monotherapy had an ORR of 11.1% (1/9) and a DCR of 77.8% (7/9). **Conclusions:** LB1410 showed an excellent safety profile and promising antitumor efficacy in pts with immune-oncology (IO)-R/R CC. Further studies of LB1410 as monotherapy and in combination with lenvatinib in pts with IO-R/R CC are ongoing. Clinical trial information: NCT05357651. Immune checkpoint inhibitor (ICI) toxicity in a large prospective cohort of patients with solid tumors: The I-CHECKIT study (SWOG S2013). First Author: Krishna Soujanya Gunturu, Hartford HealthCare Cancer Institute, Hartford, CT

Background: Based on clinical trials, the expected rate of ≥ grade 3 iRAEs is ~15% for single agent ICIs and ~30-50% for ipilumimab (ipi) plus nivolumab (nivo). Predictors of irAEs remain poorly defined, limiting clinicians' ability to anticipate and manage irAEs especially in patients treated in community practices. We conducted a prospective study to quantify the incidence and severity of irAEs across a large, diverse population of patients receiving ICI therapy and to identify clinical predictors of irAE development. **Methods:** S2013 enrolled adult patients planning to receive standard of care ICI-based therapy in two separate cohorts; only results from the completed first cohort, which received either single drug or combination (combo) ICI therapy, are reported here. Eligibility criteria were few and study included patients with active autoimmune disease, decreased performance status, and any stage of cancer. No chemo, biological or targeted therapy were permitted. Patients were followed for 1 year for the occurrence of irAE. The primary objective was to assess the occurrence of Grade >3 non-hematologic irAEs per CTCAE v5. Evaluable patients had 1 or more toxicity assessment. irAE events were centrally reviewed by the study team. **Results:** 2084 patients were enrolled and N=2,020 patients were eligible (96.9%). Mean (SD) age was 68.7 (12.5) years, 35.8% were female, 5.2% Black, and 8.0% Hispanic. Most patients received single drug (1,684; 83.4%), while 336 (16.6%) received combo. Majority of single drug patients received pembrolizumab (50.6%), followed by nivo (29.6%), durvalumab (14.0%), and ipi (13.8%). Combinations were mostly ipi plus nivo. Within the first year, 269 (13.3%) patients experienced Grade ≥3 non-hematologic irAE. The most common irAEs were hepatitis, 21.2%; gastrointestinal disorders, 19.3%; and respiratory, 10.0% (Table). IrAE incidence was higher in patients receiving combinations (27.4%) compared to single drug (10.5%; Chi-square p<.001). **Conclusions:** In this large prospective cohort with unrestrictive enrollment criteria, irAE incidence was similar to that seen in more restrictive clinical trial populations. Analysis of the clinical predictors of irAEs is in progress. Grant: NIH/NCI UG1CA189974. Clinical trial information: NCT04871542. Research Sponsor: National Cancer Institute; NIH/NCI UG1CA189974.

Grade ≥3 non-hematologic irAEs, by category.

irAE	n	%	irAE	n	%
Hepatitis	57	21.2	Metabolism/nutrition	19	7.1
Gastrointestinal	52	19.3	Musculoskeletal	12	4.5
Skin	32	11.9	Cardiac	9	3.3

COVID-19 mRNA vaccination and risk of immune-related adverse events in ICI-treated cancer patients. First Author: Andrea Yun-En Sun, College of Medicine, National Yang Ming Chiao Tung University, Taipei City, Taiwan

Background: Immune checkpoint inhibitors (ICIs) are now standard-of-care in cancer therapy; however, concerns persist regarding whether COVID-19 mRNA vaccination may enhance immune activation and exacerbate immune-related adverse events (irAEs). We evaluated the association between COVID-19 mRNA vaccination and irAE risk among patients initiating ICI therapy and assessed toxicity and survival outcomes. **Methods:** We conducted a retrospective cohort study using target trial emulation with 1:1 propensity score matching based on data from the TriNetX Research Database (January 2021–December 2025). Adult patients with metastatic cancer initiating their first ICI therapy were included. Patients with prior ICI therapy, active irAE within 30 days before ICI initiation or immunosuppressive conditions were excluded. Vaccinated patients who received COVID-19 mRNA vaccination within 100 days prior to ICI initiation were matched to unvaccinated controls. The primary outcome was composite irAE incidence over 36 months. Secondary outcomes included severe irAEs, organ-specific irAEs, all-cause mortality, pneumonia, and intensive care unit (ICU) admission. Cox proportional hazards models estimated hazard ratios (HRs) with 95% confidence intervals (CIs). E-values and quantitative bias analyses assessed robustness to unmeasured confounding. **Results:** The matched cohort included 7,218 patients (3,609 vaccinated; 3,609 unvaccinated). Vaccinated patients had a higher risk of overall irAEs (HR 1.22, 95% CI 1.17–1.28; E-value 1.74) and severe irAEs (HR 1.11, 95% CI 1.04–1.18; E-value 1.45). Organ-specific analyses demonstrated a significant increase in ocular irAEs (HR 1.48, 95% CI 1.17–1.87; E-value 2.33), with non-significant associations for dermatologic (HR 1.08, 95% CI 0.97–1.21) and rheumatologic irAEs (HR 1.12, 95% CI 0.96–1.32). No significant increases were observed for cardiac, endocrine, gastrointestinal, hematologic, or pulmonary irAEs. Despite higher irAE risk, vaccination was associated with lower all-cause mortality (HR 0.86, 95% CI 0.80–0.93) and fewer ICU admissions (HR 0.43, 95% CI 0.25–0.73). Subgroup analyses showed stronger overall irAE associations in females and patients aged $\geq$50 years. Quantitative bias analysis indicated moderate robustness, with a 74.8% probability that HR$>$1.0 persists despite plausible unmeasured confounding. All P$<$0.001. **Conclusions:** COVID-19 mRNA vaccination among patients receiving ICIs is associated with a modest increase in irAEs, particularly ocular toxicities, but may offer survival and critical illness benefits. These findings support continued vaccination in eligible ICI-treated patients, along with enhanced irAE monitoring, including ophthalmologic surveillance in higher-risk groups. Research Sponsor: None.

2642 **Poster Session**

Analysis of delta-like ligand 3 (DLL3) expression levels and characteristics of patients (pts) with advanced extrapulmonary neuroendocrine carcinomas (epNECs) from an ongoing phase I trial. First Author: Valentina Gambardella, Department of Medical Oncology, Hospital Clínico Universitario, INCLIVA Biomedical Research Institute, University of Valencia, Valencia, Spain

Background: Specific DLL3 expression on the surface of epNEC tumor cells makes it a promising therapeutic target, but there is a lack of prospective data on DLL3 expression patterns in pts with epNEC. Obrixtamig (BI 764532) is a DLL3/CD3 IgG-like T-cell engager. The first-in-human phase I trial (NCT04429087) showed obrixtamig activity in pts with DLL3-positive epNEC, especially pts with DLL3-high tumors (Capdevila et al, ASCO 2025, #3004). We report updated DLL3 expression data and pt/tumor characteristics in pts with epNEC from NCT04429087. **Methods:** DLL3 IHC was performed with an investigational DLL3 antibody (SP347) at the Roche CDx CAP/CLIA Laboratory. DLL3 expression was categorized as: negative (absent or weak tumor cell [TC] membrane/cytoplasm staining), positive (moderate-to-strong staining in any TCs), high ($\geq$50% moderate-to-strong TC staining), or low ($<$50% moderate-to-strong TC staining). **Results:** As of Sept 4, 2025, 282 of 365 screened pts with epNEC were DLL3-evaluable, of whom 235 (83.3%) had DLL3-positive tumors (DLL3-high: n=120 [42.6%], DLL3-low: n=115 [40.8%]); 47 (16.7%) were DLL3-negative. In the DLL3-positive treated set (n=93), 51 pts (54.8%) had DLL3-high and 42 (45.2%) had DLL3-low tumors. The prevalence of DLL3-high tumors in male/female pts was 47.5%/68.8%, and prevalence in pts with liver/brain metastases was 57.1%/70.0%. DLL3-high prevalence by primary tumor site, GI/GU/cancer of unknown primary site (CUP), was 44.9%/67.7%/60.0%. Pt characteristics in obrixtamig-treated DLL3-high and -low epNEC subgroups are in Table 1. **Conclusions:** In the largest prospectively screened cohort of pts with epNEC, high (83.3%) prevalence of DLL3 expression was seen, underscoring DLL3 as a promising target for clinical development of DLL3-targeted therapies such as obrixtamig. Obrixtamig safety and efficacy in pts with DLL3-positive epNEC are being assessed in several ongoing trials, including DAREON-5 (NCT05882058), with the data expected to inform and support Phase III development. Clinical trial information: NCT04429087. Research Sponsor: Boehringer Ingelheim.

Engineering tumor-infiltrating lymphocytes (TILs) via the T-Editor platform to enhance antitumor activity. First Author: Fenge Li, The First Affiliated Hospital of Nankai University, Tianjin, China

Background: Tumor-infiltrating lymphocyte (TIL) therapy has demonstrated clinical potential in melanoma, cervical cancer, and non-small cell lung cancer following failure of standard-of-care therapies, achieving objective response rates of 25-40%. However, two major challenges remain: the limited understanding of biological mechanisms underlying differential patient responses, and the absence of robust engineering technologies for manipulating fragile TIL populations. These limitations have constrained the application of genetic modification strategies to improve TIL therapeutic efficacy. **Methods:** By comparing transcriptomic profiles of infused TILs from responders (R) and non-responders (NR) in a Phase I investigator-initiated trial evaluating TIL therapy for solid tumors, we identified more than 10 differentially expressed genes as candidate therapeutic targets. We established the T-Editor platform, a CRISPR-mediated gene editing system optimized for TIL engineering, through systematic optimization of stimulation conditions, electroporation parameters, and CRISPR/Cas9 component dosing. Functional validation was performed by generating knockout (KO) constructs for each candidate gene using T-Editor, assessing their impact on TIL expansion, cytokine secretion, and cytolytic activity. The most promising target was selected for advanced cytosine base editing (CBE) studies, employing sgRNA designs to minimize Cas9-induced double-strand break risks. Base-edited TILs were comprehensively compared with Cas9-KO counterparts in vitro, while in vivo efficacy was evaluated using patient-derived xenograft (PDX) mouse models. **Results:** The T-Editor platform we established achieved optimal gene editing efficiency with defined stimulation condition, electroporation program and CRISPR/Cas9 doses. Functional screening revealed four critical regulatory genes, with FAM84B emerging as the most significant target where knockout demonstrated an increase in cytolytic activity compared to controls. CBE-mediated C·G→T·A conversion at FAM84B exon achieved high editing efficiency with minimal insertion-deletion events. Base-edited TILs showed comparable expansion kinetics, phenotypic stability, and cytokine production to Cas9-KO counterparts. In vivo studies demonstrated increased tumor growth inhibition in PDX models with FAM84B-edited TILs, which exhibited enhanced memory phenotype, superior effector function and elevated IFN-γ secretion. **Conclusions:** The T-Editor platform represents a rapid, efficient, and safe CRISPR-based system for TIL engineering, enabling both gene knockout and precise base editing applications. Our discovery of FAM84B as a potential novel inhibitory regulator of TIL function establishes a promising therapeutic target for improving adoptive cell therapy outcomes in solid tumor treatment. Research Sponsor: None.

Atezolizumab (A) plus pertuzumab/trastuzumab/hyaluronidase (PHESGO) in patients (pts) with solid tumors with *ERBB2* alterations (alt): Results from the Targeted Agent and Profiling Utilization Registry (TAPUR) study. First Author: Timothy Lewis Cannon, Inova Schar Cancer Institute, Fairfax, VA

Background: TAPUR is a phase II basket study evaluating the antitumor activity of commercially available targeted agents in pts with advanced cancers with specific genomic alts. Results of a cohort of pts with solid tumors with *ERBB2* alts treated with A+PHESGO are reported. **Methods:** Eligible pts had measurable disease, ECOG performance status (PS) 0-2, adequate organ function, and no remaining standard treatment (tx) options. Genomic testing was performed in CLIA-certified, CAP-accredited labs. Dosing for A was 1200 mg IV delivered every 3 weeks (wks). PHESGO was dosed every 3 wks, with a loading dose of 1200 mg/600 mg/30,000 units, then 600 mg/600 mg/20,000 units, until progression. Primary endpoint was disease control (DC) per investigator defined as objective response (OR) or stable disease (SD) of at least 16 wks duration (SD16+) per RECIST v.1.1. Simon 2-stage design tested null DC rate of 15% vs. 35% (power = 0.85; α = 0.10). If $\geq$2/10 pts in stage 1 had DC, cohort expanded to stage 2; otherwise, the cohort was closed. Cohorts closed prior to reaching the protocol-specified sample size of 28 used alternative thresholds set forth in the protocol to maintain the α level. For n=20, 6 pts had to have DC to reject the null (power = 0.74). Secondary endpoints were OR, progression-free survival (PFS), overall survival (OS), duration of response and SD, and safety. **Results:** The cohort expanded to stage 2 but closed before reaching the planned sample size. 23 pts with 6 tumor types (colorectal [CRC; 14], gallbladder [GB; 3], stomach [3], breast [1], pancreas [1], small intestine [1]) with *ERBB2* amplification (amp; n=16), *ERBB2* overexpression (n=2), *ERBB2* mutation (mut; n=2), and *ERBB2* amp and mut (n=3) were enrolled. 3 pts were not evaluable. 2 partial responses (both GB, *ERBB2* amp) and 2 SD16+ (both CRC, *ERBB2* amp) were observed for a DC rate of 25% (1-sided 90% CI, 10 to 100) and an OR rate of 10% (95% CI, 1 to 32). The null hypothesis was not rejected (p=0.26). 6 pts had tx-related grade 3 AE/SAEs: acute kidney injury, ALP increase, dehydration, diarrhea, infusion related reaction, lymphopenia, maculo-papular rash, pneumonitis and sepsis. **Conclusions:** A+PHESGO did not demonstrate sufficient antitumor activity in pts with *ERBB2*-altered solid tumors to warrant further study. However, the cohort did not reach its planned accrual, limiting statistical power for demonstrating efficacy. Other tx should be considered for these pts, including tx offered in clinical trials. Clinical trial information: NCT02693535. Functional assessment of polymerase proofreading variants to define sensitivity to immune checkpoint blockade (ICB) pan-cancer. First Author: Amin Nassar, Yale Cancer Center, New Haven, CT

Background: Cancers with inactivating alterations in DNA proofreading polymerases POLE and POLD1 (POLd) are ultra-hypermutated and benefit from ICB. Most mutations in DNA polymerases are synonymous; discerning pathogenic (P) vs variants of unknown significance (VUS) remains challenging. A strategy to define functional mutations in POL with mutational signature deconvolution and AI- protein conformational modeling could better predict ICB benefit. **Methods:** Solid tumors from patients at MSK and DFCI were selected with DNA panel sequencing datasets to enrich for somatic POL P/likely-P(LP) variants or VUS. Co-mismatch-repair deficiency (MMRd) was defined with MSIsensor and IHC. Tumors were assigned as POL high (>50%), intermediate ([int] 1-49%), or null (0%) based on the proportion of single-base-substitutions (SBS) aligning with POLd COSMIC signatures via the mutational-patterns algorithm. *POLE/D1* VUS were functionally evaluated with Swiss-PdbViewer and AlphaFold-derived AI models to infer proofreading efficiency impact. Patient overall survival (OS) from stage IV diagnosis and progression-free survival from ICB start (PFS-ICB) were evaluated with multivariable (MV) Cox regression including MMRd status. **Results:** POL variants were found in 546 patients across 18 diverse cancers. 84% were P/LP POL alterations, 16% were POL VUS, and 36% overall had concomitant MMRd. Tumors with P/LP variants had high (69%), int (23%), or null (8%) POLd signature intensities, while 62% of tumors with VUS had int POLd signatures. For the subgroup of patients with POL P/LP variants, OS from diagnosis significantly differed based on POLd signature intensity: not reached [NR], 94.5 months [mo], and 32.9 mo for POLd signature high, int, and null, respectively. In MV analysis of POL P/LP tumors, patients with POL signature-null tumors had significantly worse OS than POL-int (HR 0.35, 95%CI 0.16-0.80; p=0.01) and POL-high (HR 0.18, 95%CI 0.08-0.42; p<0.001) patients. POLd signature intensity predicted ICB benefit. Patients with POL P/LP tumors with high and int signatures exhibited favorable PFS-ICB (NR in both) versus POL P/LP–null-signature tumors (12.7 months). In MV model including MMR status, patients with POL-null SBS exhibited significantly worse PFS-ICB versus pts with combined POL signature high or int (HR 0.31, 95% CI 0.10-0.98; p=0.047). Study findings were consistent after adjustment for cancer type. Tumors with POL VUS predicted to be inactivating based on mutational signature deconvolution combined with Swiss-PdbViewer and AlphaFold AI models demonstrated similar OS/PFS to patients with tumors with P/LP variants and high/int signature scores. **Conclusions:** A strategy combining mutational signature deconvolution with AI proteomic functional assessment predicts survival and ICB benefit in tumors with functional DNA polymerases *POLE* and *POLD1* mutations. Development and testing of an ex vivo, live tumor fragment platform for the prediction of immune checkpoint inhibitor response and relationship to approved biomarkers. First Author: David A. Braun, Center of Molecular and Cellular Oncology, Yale Cancer Center, Yale School of Medicine, New Haven, CT

Background: Immune checkpoint inhibitors (ICIs) have transformed the management of many advanced cancers but identifying patients who are likely or unlikely to benefit from ICI treatment remains a critical challenge. Biomarkers, such as PD-L1, mismatch repair deficiency, and tumor mutational burden, capture only static, unidimensional features of the complex tumor microenvironment, and therefore inadequately predict response to immunotherapy in patients. In contrast, live tumor fragments (LTFs) preserve the full complexity of the tumor microenvironment and enable functional ex vivo assessments of ICI activity. Previous efforts have had limited clinical applicability because they required larger resection specimens often collected at a single academic center. Here, the predictive capability of an ex vivo platform using core needle and forceps biopsies from multiple clinical sites was assessed and compared to approved biomarkers. **Methods:** Patients with eligible solid tumors (where ICI has an indication, including renal, non-small cell lung, bladder, colorectal, and triple-negative breast cancer, and others) were enrolled in ongoing, prospective observational trials (NCT05478538, NCT05520099, NCT06349642). Biopsies were cut into LTFs, encapsulated in hydrogel, and treated sequentially with IgG antibody followed by ICI (αPD-[L]1 with or without αCTLA-4). Cytokine production was assessed by a multiplexed bead-based immunoassay at multiple time points during ex vivo treatment. Using receiver operating characteristic and precision recall analyses, we identified 9 predictive cytokines (including IFN-γ, granzyme B, and CXCL9/10), which were used to develop the Elephas score (ELP-score) to assess cytokine response to ex vivo ICI treatment. **Results:** Of 167 eligible patient specimens, 85% (n = 142) passed quality control metrics and 130 were used for model development. Hierarchical clustering of cytokine production revealed that 27% (n = 35) of patient specimens exhibited a cytokine response to ICI. In a validation set of 20 tumors, collected from patients who were subsequently treated with ICI, ELP-score positivity correctly identified 9 of 11 patients (82%) who had an objective response (PR/CR) to ICI, including 2 patients who were negative for FDA-approved standard-of-care ICI biomarkers. Furthermore, 5 of 5 patients (100%) with clinical progressive disease were correctly characterized as ELP-score negative. **Conclusions:** Using routine biopsy specimens, the ex vivo live tumor platform accurately identifies patients with clinical response to ICI therapy, including those incorrectly identified by conventional biomarkers. Ongoing efforts will test these findings in an additional validation set. If confirmed, the ex vivo LTF platform could enable the identification of patients likely to benefit from ICI therapy. Clinical trial information: NCT05478538, NCT05520099, NCT06349642. Research Sponsor: Elephas.

Mitochondrial DNA (mtDNA) expression as used to define metabolic and immune states in colorectal cancer (CRC). First Author: Michela Bartolini, Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy

Background: CRC exhibits metabolic reprogramming driven by the Warburg effect; however, active mitochondria and oxidative phosphorylation (OXPHOS) often remain crucial for tumor growth. mtDNA encodes critical OXPHOS components and influences the balance between OXPHOS and glycolysis, with effects on tumor microenvironment and response to immune checkpoint inhibitors (ICIs). We evaluated whether mtDNA gene expression predicts metabolic phenotype, immune contexture and benefit from ICIs. **Methods:** 30,887 CRC cases with DNA/RNA sequencing were analyzed from Caris Life Sciences. Expression of mtDNA-encoded OXPHOS genes (*MT-ND1–6, MT-ND4L, MT-CO1–3, MT-ATP6, MT-CYB*) was summarized as a composite Z-score due to correlation (r>0.9). Tumors were stratified into quartiles (n=7,722 each), mtDNA-high (MT-H, top quartile) and mtDNA-low (MT-L, bottom quartile) cohorts. Overall Survival (OS) was calculated in months (m) from first treatment to last contact. Hazard ratios (HRs) were calculated using Cox proportional hazards models and p-values by log-rank tests. Gene set enrichment analysis (GSEA) was performed to evaluate pathway differences. **Results:** MT-H tumors were enriched for Consensus Molecular Subtype (CMS) 2 compared to MT-L (44.2% vs 21.9%) and CMS3 (24.5% vs 8.7%), whereas CMS4 was markedly enriched in MT-L tumors (MT-H 16.5% vs MT-L 52.2%); all p<0.001. GSEA showed a trend toward higher OXPHOS activity in MT-H tumors (NES 1.19, FDR q=0.472), while glycolysis was significantly downregulated (NES -2.43, FDR q=0.002), with low immune/inflammatory signaling (interferon signaling and inflammatory response, among others) and reduced immune cell infiltration. These associations persisted in microsatellite stable (MSS) CRC, including CMS (CMS2/CMS3 46.3%/24.9% in MT-H vs CMS4 55.6% in MT-L) and immune signatures (all q<0.05). MT-L was prognostic for improved OS vs MT-H (median OS [mOS] 30.1 vs 27.2 m; HR 0.87, 95% CI 0.84-0.91, p<0.001). In ICI-treated patients (pts), MT-L showed amplified effect (mOS 24.3 vs 13.5 m; HR 0.69, 95% CI 0.58-0.83, p<0.001), including in CMS1 (mOS 39.3 vs 26.0 m; HR 0.71, 95% CI 0.53-0.96, p=0.024), CMS4 (mOS 19.3 vs 10.7 m; HR 0.61, 95% CI 0.40-0.94, p=0.024), MSS (mOS 13.8 vs 9.02 m; HR 0.67, 95% CI 0.54-0.84, p<0.001) and in pts with liver metastases (mOS 13.4 vs 7.93 m; HR 0.65, 95% CI 0.44-0.97, p=0.034). Multivariate analysis adjusting for age (>65 years), sex, liver metastases, MSI status, *BRAF V600E* status and CMS confirmed MT-L to be independently associated with improved OS in ICI-treated pts (p=0.01). No survival association was observed in pts treated with other therapies. **Conclusions:** mtDNA-encoded OXPHOS expression defines biologically distinct CRC subsets with distinct metabolic states and immune infiltration, with MT-L linked to improved OS and enhanced benefit from immunotherapy, including in MSS and liver metastases where ICI sensitivity is limited. Research Sponsor: None.

Pan-cancer long mononucleotide repeat microsatellite instability testing for detection and immunotherapy selection. First Author: Ruchi Shah, Department of Medicine, University of Wisconsin-Madison, Madison, WI

Background: Microsatellite instability (MSI) and mismatch repair deficiency (dMMR) are crucial biomarkers to inform potential for hereditary risk and eligibility for immunotherapy across multiple cancers. While current standard of care testing can identify most MSI-high (MSI-H)/dMMR patients, improved testing sensitivity for MSI-H status could identify more patients who may benefit from immunotherapy. Recent studies have indicated potential for more sensitive testing using a long mononucleotide repeat (LMR)-based multiplex MSI-detection assay. **Methods:** Patients were identified and consented as part of an IRB-approved protocol (UW15068) based on MSI status, MMR gene variants, or high tumor mutation burden (TMB). Patient tissues, normal and tumor, were formalin-fixed and slides were prepared for pathologist annotation and immunohistochemistry (IHC) for CD8. CD8+ tumor infiltrating lymphocytes (TILs) were quantified/high powered field (HPF). Slides were scraped for DNA isolation. MSI testing was performed on the resultant DNA using the LMR MSI Analysis System (Promega, Madison, WI) and the OncoMate MSI Dx Analysis system (OM, Promega) per manufacturer protocols. LMR MSI status and score were compared with other testing methods, TMB, CD8+ TILs/HPF, immunotherapy response, progression-free survival (PFS), and overall survival (OS). **Results:** A cohort of 202 patients (median age: 64 (range: 24-80+)) with 20+ different cancer types (lung 27.2%, colorectal 18.8%, skin 9%, esophageal 5.9%, uterine 5.9%) and across disease stages, mutation profiles, and immunotherapy treatment regimens were consented. At least one test identified a case as dMMR/MSI-H in 31.6% of cases. In 9.4% of cases, a discrepancy between testing methods was observed. LMR detected 9 cases as MSI-H that were not detected by clinical NGS or OM. 4 cases were detected as MSI-H by LMR and OM alone, one case by OM alone, and one case by LMR and clinical NGS alone. Additionally, 2 cases were dMMR by IHC but not LMR, OM, or clinical NGS and 2 cases were dMMR by IHC and MSI-H by clinical NGS, but not LMR or OM. LMR score positively correlated with TMB (r^2 = 0.57) for MSI-H, but not MSS patients (r^2 = 0.002). LMR score weakly correlated with CD8+ TILs/HPF (r^2 = 0.16) in MSI-H, but not MSS cases (r^2 <0.001). LMR MSI-H cases have a 52.6% complete response rate compared to 6.12% of LMR MSS subjects (p<0.001). Patients identified as MSI-H by LMR testing had an increased PFS (median PFS (days) MSI-H: 711, MSS: 178; hazard ratio (HR) 0.25 [95% CI 0.13-0.50; p<0.001]) and OS (median OS (days) MSI-H: 926, MSS: 402; HR 0.43 [95% CI 0.22-0.82; p=0.015]) compared to LMR MSS patients. **Conclusions:** Variability can be observed between dMMR/MSI testing methods indicating that multiple methods should be considered for each patient. LMR testing demonstrates promising sensitivity and correlation with immunotherapy efficacy. Research Sponsor: Promega.

Are all tumor-agnostic biomarkers equally tissue-independent? Comparative cross-histology efficacy analysis of MSI-H/dMMR versus *BRAF* V600E. First Author: Victor Andres Castillo, Autonomous University of Baja California, Tijuana, BJ, Mexico

Background: FDA tumor-agnostic approvals for pembrolizumab/dostarlimab (MSI-H/dMMR) and dabrafenib-trametinib (BRAF V600E) assume uniform cross-histology efficacy. However, MSI-H/dMMR depends on immune checkpoint blockade—potentially influenced by tissue-specific microenvironments—while BRAF V600E represents oncogene addiction with essential MAPK dependencies. We hypothesized these biomarkers differ in tissue independence, with MSI-H/dMMR demonstrating greater histology-dependent response variability. **Methods:** A systematic review and meta-analysis were conducted in accordance with PRISMA 2020 guidelines. PubMed, Embase, and the Cochrane Central Register owere searched from inception to January 2026 to identify prospective basket trials enrolling adults ($\geq$18 years) with advanced or metastatic solid tumors harboring FDA-approved tumor-agnostic biomarkers. Eligible trials evaluated pembrolizumab or dostarlimab in MSI-H/dMMR tumors, or dabrafenib plus trametinib in BRAF V600E-mutant tumors, and reported objective response rates (ORR) stratified by tumor histology. Studies were required to include $\geq$3 distinct tumor histologies (not subtypes) with a minimum of 10 patients per histology cohort. Phase I trials, retrospective case series, pediatric-only populations, and studies without histology-specific efficacy data were excluded. Primary outcome was ORR heterogeneity across tumor types within each biomarker platform, quantified using the I^2 statistic and coefficient of variation (CV). Pooled analyses were performed using random-effects models. Effect estimates are expressed as ORR percentages with 95% confidence intervals. **Results:** Four trials included: KEYNOTE-158 (pembrolizumab, n=373), GARNET (dostarlimab, n=363), ROAR (dabrafenib-trametinib, n=215), VE-BASKET (vemurafenib, n=62); 1,013 patients across 12 tumor histologies. MSI-H/dMMR platform (n=736, 8 tumor types): mean ORR 35.1% (range 0-57.1%); endometrial 57.1%, gastric 45.8%, colorectal 43.5%, small intestine 42.1%, cholangiocarcinoma 40.9%, ovarian 33.3%, pancreatic 18.2%, brain 0%; CV=0.513. BRAF V600E platform (n=277, 4 tumor types): mean ORR 45.0% (range 37.1-53%); anaplastic thyroid 53%, biliary tract 47%, glioma 42.9%, NSCLC 37.1%; CV=0.149. MSI-H/dMMR demonstrated 3.4-fold greater heterogeneity than BRAF V600E (CV 0.513 vs 0.149). **Conclusions:** Tumor-agnostic biomarkers exhibit differential tissue independence. MSI-H/dMMR showed 3.4-fold greater response heterogeneity (CV=0.513) than BRAF V600E (CV=0.149), indicating immune checkpoint efficacy remains tissue-dependent while oncogene addiction confers uniform predictivity. These findings challenge the assumption of biomarker-driven tissue-agnostic efficacy and necessitate histology-specific outcome counseling and trial stratification. Research Sponsor: None.

Pan-cancer landscape of oncogenic POLE and POLD1 alterations. First Author: Lawrence W. Wu, Columbia University Irving Medical Center, New York, NY

Background: POLE and POLD1 encode key enzymes for DNA proofreading. Oncogenic alterations in POLE and POLD1 associated with defective proofreading can lead to tumor hypermutation and increased sensitivity to immune checkpoint inhibition. Prior studies have identified enrichment of POLE and POLD1 alterations in colorectal and endometrial cancers. However, characterization of POLE and POLD1 alterations in the pan-cancer setting has been limited. Utilizing the American Association for Cancer Research (AACR) Project Genomics Evidence Neoplasia Information Exchange (GENIE) v19.0, we performed a comprehensive analysis of oncogenic POLE and POLD1 alterations across tumor types. **Methods:** The AACR GENIE v19.0 database was used to select tumor samples that were profiled for molecular alterations (somatic mutations, structural variants, copy number alterations) in POLE or POLD1. POLE and POLD1 alterations were annotated by OncoKB to determine if they were oncogenic. Tumor samples were analyzed for co-occurring molecular alterations. Categorical variables were compared using chi-square or Fisher exact tests, as appropriate. P-values were adjusted with Benjamini-Hochberg correction to control false discovery rate (significance for $q<0.05$). **Results:** Across 188,863 tumor samples that were profiled for POLE or POLD1, there were known oncogenic alterations in 786 samples (0.4%). Of note, there were 18,170 molecular alterations in POLE and POLD1 that were classified as variants of unknown significance at time of analysis. The most common tumor types with oncogenic alterations were endometrial (n=374 of 7573 samples profiled; 4.9%), colorectal (143/17821; 0.8%), glioma (49/12795; 0.4%), NSCLC (35/30542; 0.1%), ovarian (26/7728; 0.3%), breast (25/16813; 0.2%), bladder (25/6433; 0.4%), cancer of unknown primary (19/6544; 0.3%), melanoma (13/7965; 0.2%), and pancreatic (10/10369; 0.1%), and esophagogastric (9/6503, 0.1%). The most common mutations in POLE were V411L, E18K, P286R, S297F, and A456P. The most common mutations in POLD1 were R1016H, R1016C, R689W, L606M, and D402N. Oncogenic alterations in POLE and POLD1 were enriched in endometrial cancer (OR 22.8; $q<0.001$) and colorectal cancer (OR 2.14; $q<0.001$), with no other tumor types showing enrichment. Within the oncogenic POLE/POLD1 cohort, the most common co-occurring molecular alterations were in PIK3CA (n=561, 71.4% in altered vs 12.9% in unaltered, $q<0.001$), APC (n=526, 68.7% vs 11.8%, $q<0.001$), ATM (n=523, 67.8% vs 7.3%, $q<0.001$), and PTEN (n=523, 66.5% vs 8.7%, $q<0.001$). **Conclusions:** To our knowledge, this study represents the largest molecular analysis of oncogenic POLE and POLD1 alterations in a pan-cancer setting. These findings suggest that oncogenic POLE and POLD1 alterations may be rarely identified in a broad range of tumor types. Further studies are needed to classify the functional implication of many variants of unknown significance in POLE and POLD1. Research Sponsor: None.

Phase Ib evaluation of a recombinant overlapping peptide survivin immunotherapy: Safety, immunogenicity, and immune–clinical associations in advanced solid tumours. First Author: Shisong Jiang, Department of Oncology, University of Oxford, Oxford, Oxfordshire, United Kingdom

Background: Survivin (BIRC5) is a tumour-associated self-antigen broadly expressed in solid malignancies but subject to immune tolerance, limiting its value as an immunotherapy target. OVM-200 is a recombinant overlapping peptide (ROP) survivin immunotherapy designed to enhance antigen processing and presentation through both MHC class I and II pathways, thereby overcoming HLA restriction. A Phase Ia study established safety and the recommended regimen. Here we report novel Phase Ib data evaluating extended immunisation and immune–clinical associations. **Methods:** Phase Ib enrolled a total of 24 patients with advanced NSCLC, ovarian, or prostate cancer who had progressed on standard therapies. Patients received OVM-200 at the recommended regimen (2 mg) with extended immunisation schedules (3–11 immunisations). The primary endpoint was safety and the secondary endpoint was immunogenicity. Survivin-specific antibodies were measured by IgG ELISA and T-cell responses by IFN-γ ELISpot. Tumour response was assessed using RECIST 1.1, with best overall response (BOR) classified as stable disease (SD) or progressive disease (PD). Immune responses were analysed longitudinally and in relation to BOR. **Results:** The primary endpoint of safety was met, with OVM-200 well tolerated and no dose-limiting toxicities or treatment-related serious adverse events. Survivin expression was detected in tumour tissue in 17 patients prior to immunisation; however, baseline survivin-specific antibody and T-cell responses were low or undetectable, consistent with immune tolerance. The secondary endpoint of immunogenicity was achieved. Mean peak anti-survivin antibody titres increased from 1:143 pretreatment to >1:160,000 post-treatment ($p < 0.001$), and mean peak T-cell responses increased from 211 to 859 net SFU/10^6 PBMCs ($p < 0.00001$). Antibody responses were durable, rising through Days 113–169, whereas T-cell responses peaked at Day 57 and remained significantly above baseline. Extended immunisation (>5 immunisations) maximised humoral responses, while T-cell magnitude was comparable across schedules. Patients with BOR of SD showed higher and more sustained survivin-specific humoral and cellular immune responses than those with PD. **Conclusions:** Phase Ib results demonstrate that OVM-200 is safe and immunogenic, achieving both the primary safety and secondary immunogenicity endpoints. OVM-200 overcomes immune tolerance to survivin and induces durable humoral and cellular immune responses. The observed association between stronger immune responses and BOR of SD supports further clinical evaluation and rational combination strategies. Clinical trial information: NCT05104515. Research Sponsor: Oxford Vacmedix.

Monitoring blood-based biomarkers as early predictors of progression-free survival in a randomized Bria-ABC phase 3 trial for advanced metastatic breast cancer: An ongoing analysis. First Author: Daniel L. Adams, Creatv MicroTech, Inc., Monmouth Junction, NJ

Background: Circulating Tumor Cells (CTCs) are prognostic for poor outcomes in metastatic Breast Cancer (mBC), however CTCs are uncommon in mBC (<20%) and many pts without CTCs often progress. Cancer associated macrophage-like cells (CAML) are prognostic inflammatory pro-tumorigenic PD-L1 expressing macrophages common in mBC pt blood (>90%). In a previous randomized phase II trial, CTC & CAML decreases post Bria-IMT induction correlated with clinical benefit. Bria-IMT is an allogenic whole cell vaccine engineered to express tumor associated antigens & GM-CSF, promoting adaptive & innate immune responses. The ongoing Bria-ABC (NCT06072612) phase 3 study compares Bria-IMT to physician's choice (TPC) in late stage mBC. We present interim results, without treatment arm comparison, for Progression Free Survival (PFS) by CTC & CAML changes as the exploratory part of the trial. **Methods:** This still blinded ongoing multicenter randomized open label Phase 3 trial evaluates Bria-IMT+ checkpoint inhibitor (CPI) vs TPC in mBC pts lacking approved therapies. Pts are randomized 1:1:1 to Bria-IMT+CPI, TPC, or Bria-IMT monotherapy (discontinued after 150 pts). The Bria-IMT consists of cyclophosphamide, irradiated SV-BR-1-GM cells, micro-dose pegylated α IFN at each inoculation site. CPI is administered day -3 to 3. TPC followed standard of care. Blinded anonymized blood was taken at baseline (BL), prior to therapy & 2nd (T1) taken at cycle 3 (~4 weeks post initiation). CTCs & CAMLs, and PD-L1 expressions, were quantified using LifeTracDx liquid biopsy with analysis of PFS by censored univariate analysis. **Results:** At time of analysis, >250 consented, >170 randomized, 119 had BL and 78 had T1. Median age 56 yrs [34–83], median 6 [2–13] prior lines of therapy, 31% TNBC, 62% ER+/PR+, & 15% HER2+. $\geq$1 CTCs were found in 25% (30/119) at BL & 22% (17/78) at T1. $\geq$1 CAMLs were found in 93% (111/119) at BL & 95% (74/78) at T1. At BL, $\geq$1 CTC was not significant for PFS (HR=1.7, CI95% 1.0-2.9, p=0.0513), but $\geq$2 CTCs was significant for worse PFS (HR=1.8 CI95% 1.1-3.1, p=0.0480). At T1, $\geq$1 CTCs nor $\geq$2 CTCs correlated with PFS (HR=0.9, p=0.8392) & (HR=1.6, p=0.1079), respectively. Further, a decrease in CTCs was seen in 11 pts but did not correlate with PFS (HR=0.7, p=0.6552). $\geq$1 CAML at BL nor T1 correlated with PFS (HR=1.2 CI95% 0.7-2.0, p=0.6811) or (HR=0.9 CI95% 0.7-2.5, p=0.5307), respectively. However, 51 pts (65%) had a decrease or stable CAML counts between BL & T1 which did significantly correlate with better PFS (HR=2.2 CI95% 1.2-3.9, p=0.0154). **Conclusions:** In an ongoing analysis of a heavily treated mBC pts, we observed that in the entire blinded population, 65% of pts had stability/drop in CAMLs significantly correlated with better PFS. Treatment arm specific comparisons will not be unblinded until completion of the designated milestone (144 mortalities). Clinical trial information: NCT06072612. Research Sponsor: Creatv Microtech; BriaCell Therapeutics Corp.

Off-target HLA matches for prediction of response in personalised cancer vaccines: A multi-trial retrospective analysis. First Author: Om H. Gandhi, Centre for Immuno-Oncology, University of Oxford, Oxford, United Kingdom

Background: Personalized neoantigen vaccines aim to match epitopes to a patient's HLA genotype, yet many peptides bind promiscuously across multiple HLA alleles. Promiscuous binding may reflect intrinsic peptide properties, including enhanced processing efficiency and structural stability, that drive immunogenicity independent of any single HLA match. We hypothesized that peptides with broader HLA binding profiles would show higher clinical immunogenicity, even when restricted to the patient's own HLA alleles. **Methods:** We curated 17 neoantigen vaccine trials (174 patients) and selected five with per-epitope $CD8^+$ T cell immunogenicity data for primary analysis. Across 571 neoantigen sequences (3,806 derived peptides), we predicted binding and presentation using NetMHCpan-4.2, MHCflurry 2.0, and PRIME-2.0, and estimated peptide–MHC stability with NetMHCstabpan. A reference panel of 62 common HLA class I alleles (>95% global coverage) was used to quantify incidental coverage, defined as predicted binding (IC50 <500 nM) to non-patient HLA alleles. Mixed-effects models adjusted for patient-specific binding affinity, predicted stability, mutation type, neoantigen length, and trial structure, with Bonferroni correction for 5 pre-specified hypotheses. **Results:** Off-target HLA binding independently predicted clinical immunogenicity. Among peptides selected for vaccination, 35.2% bound at least one non-patient HLA allele, with the most promiscuous peptides binding up to 37 alleles. After adjusting for patient-specific binding affinity and stability, peptides from immunogenic neoantigens showed greater incidental coverage than non-immunogenic peptides (mean 2.46 vs 1.80 additional HLAs; p=0.0034). This association was consistent across tumour types and prediction methods. Among immunogenic peptides, the breadth of off-target binding correlated with response magnitude (Spearman ρ=0.46, p=0.034), with the strongest effect observed in glioblastoma. High-affinity off-target matches (IC50 <50 nM) and high-stability interactions showed the most robust associations with immunogenicity. **Conclusions:** Promiscuous HLA binding independently predicts neoantigen immunogenicity in clinical trials, beyond binding affinity and stability to the patient's own HLA alleles. These results point to peptide-intrinsic properties linked to MHC stability and processing that are overlooked by current selection pipelines. Explicit modelling of HLA promiscuity and stability may improve neoantigen prioritisation, particularly in low–mutation burden tumours and patients with rare HLA genotypes. Research Sponsor: None.

Ranking neoantigens for escape-resilience rather than predicted immunogenicity: Associated changes in vaccine design. First Author: Michael E. Bryan, Centre for Immuno-Oncology, University of Oxford, Oxford, United Kingdom

Background: Personalised neoantigen vaccines induce detectable $CD8^+$ T cell responses for fewer than one-third of selected peptides. Current pipelines prioritise candidates by predicted immunogenicity and select peptides independently, overlooking two constraints: efficacy depends on the peptide set as a whole, and tumours adapt antigen processing under immune pressure. We developed a framework that optimises peptide combinations for resilience to tumour escape and tested whether escape-resilience predicts clinical immunogenicity. **Methods:** We modelled peptide susceptibility to five antigen-processing escape mechanisms: TAP downregulation, immunoproteasome-to-constitutive proteasome switching, aminopeptidase upregulation, tapasin loss, and HLA loss of heterozygosity. Selection was formulated as a minimax optimisation, maximising predicted efficacy under worst-case tumour adaptation. We analysed five neoantigen vaccine trials with per-epitope $CD8^+$ T cell response data, consisting of 571 neoantigens, 3,806 peptides, and 174 patients. Mixed-effects models tested associations between escape-resilience and immunogenicity, adjusting for binding affinity (NetMHCpan-4.1 %rank), pMHC stability (NetMHCstabpan), mutation type, and clonality. Six hypotheses were pre-registered with Bonferroni correction. **Results:** Escape-resilience predicted immunogenicity independently of established features. After adjustment, vulnerability to TAP loss (OR 0.42 per SD, 95% CI 0.24–0.71, p=0.0018) and proteasome switching (OR 0.54 per SD, 95% CI 0.34–0.86, p=0.0089) were associated with failure to elicit $CD8^+$ responses. Among peptides with comparable predicted binding affinity, escape-resilient peptides were significantly more likely to be immunogenic. Composite escape-resilience scores discriminated immunogenic from non-immunogenic peptides (AUC 0.71, 95% CI 0.66–0.76), outperforming binding affinity alone (AUC 0.58) and an affinity-stability model (AUC 0.64). Adding escape-resilience improved discrimination (ΔAUC 0.07, p=0.003). Retrospective re-ranking altered 38% (95% CI 31–45%) of vaccine compositions, replacing high-affinity but escape-vulnerable peptides with lower-affinity, processing-robust alternatives. Associations were stronger for truncal mutations (OR 2.8, 95% CI 1.6–4.9) than subclonal mutations (OR 1.4, 95% CI 0.8–2.4; interaction p=0.041), indicating that processing robustness is most consequential for clonally dominant neoantigens. **Conclusions:** Optimising neoantigen selection against tumour escape identifies peptides more likely to elicit $CD8^+$ T cell responses, independent of binding affinity and stability. The stronger effects in truncal mutations suggest escape-aware ranking may be particularly valuable for durable, clone-targeted vaccination strategies. Prospective trials are needed to assess clinical impact. Research Sponsor: None.

The differentiated SIRPα–IgG4 Fc fusion protein HCB101 in monotherapy and combination therapy. First Author: Fangling Ning, Binzhou Medical University Hospital, Binzhou, China

Background: The CD47–SIRPα axis is a central innate immune checkpoint that enables tumor immune evasion. No prior CD47-directed program has demonstrated meaningful monotherapy activity, limited by on-target hematologic toxicity, constraining development. HCB101 is a differentiated SIRPα–IgG4 Fc fusion protein engineered to maintain macrophage-mediated phagocytosis while reducing red-blood-cell binding. This study assesses whether HCB101 can overcome historical class limitations by achieving a wide therapeutic safety margin and durable monotherapy antitumor activity, while also serving as a backbone for combination immunotherapy efficacy across standard-of-care (SOC) regimens. **Methods:** HCB101-101 (NCT05892718) is a first-in-human Phase 1 monotherapy dose-escalation study evaluating weekly IV dosing from 0.08 to 36 mg/kg. HCB101-201 (NCT06771622) is a Phase 1b/2a multi-cohort trial assessing HCB101 combined with SOC agents across 9 solid tumor types, including gastric cancer (GC), triple-negative breast cancer (TNBC), colorectal cancer, head and neck squamous cell carcinoma (HNSCC), hepatocellular carcinoma, ovarian cancer, and small cell lung cancer. Primary endpoints are safety, tolerability, and determination of the recommended Phase 2 dose; secondary and exploratory endpoints include pharmacokinetics (PK), pharmacodynamics, efficacy, and biomarkers. **Results:** In HCB101-101, 36 mg/kg has been reached. To 09JAN2026, 2 confirmed partial responses (HNSCC: −42% at 5.12 mg/kg, durable > 44 weeks; marginal zone lymphoma), and 9 stable diseases (SD) have been observed. PK was dose-proportional ($T_{1/2}$ ~2.9 days) with receptor occupancy plateauing at > 99% by ≥8 mg/kg. In HCB101-201, 2L-GC treated with HCB101 plus ramucirumab and paclitaxel demonstrated 8 PRs and 5 SDs, with two additional patients at 12 mg/kg pending first assessment. In mid-dose cohorts (5.12–8 mg/kg), 8 of 10 subjects achieved PRs and 100% achieved disease control, with regressions up to −78.2%. In 1L HER2+ GC, 4 subjects showed 3 PR (up to −57.6%) and 1 SDs. In 1L-TNBC, 6 of 6 subjects achieved disease control, including 3 PRs. Across cohorts, HCB101 demonstrated manageable safety with reversible cytopenias and no unexpected immune-mediated toxicities. **Conclusions:** HCB101 demonstrates a class-distinguishing profile for a macrophage checkpoint inhibitor, with durable monotherapy antitumor activity and a wide therapeutic window up to 36 mg/kg, addressing long-standing limitations of CD47-directed therapies. The early and reproducible combination activity across multiple solid tumors, including GC, HER2+ GC, and TNBC, has supported rapid cohort expansion. These data position HCB101 as a next-generation innate immune checkpoint backbone with broad clinical applicability and a clear rationale for future combination-based registrational development. Clinical trial information: NCT05892718. Research Sponsor: None.

Low-dose nivolumab in patients at high risk of immune-related adverse events: A retrospective cohort study. First Author: Lisa May Ling Tachiki, University of Washington, Seattle, WA

Background: Immune checkpoint inhibitors (ICIs) are relatively contraindicated in patients with prior severe immune-related adverse events (IRAEs) and/or have pre-existing serious auto-immune diseases (AID). Such patients are generally excluded from immunotherapy trials due to toxicity concerns, and data on ICI (re)exposure is limited. Our correlative data [Tachiki L 2024 SITC] suggest that low-dose (LD) nivolumab (Nivo; 40 mg) achieves PD-1 receptor occupancy comparable to standard-dose (SD) Nivo (240 or 480 mg), suggesting a potentially similar risk of developing IRAEs. However, faster serum clearance observed with LD Nivo may allow easier management of IRAEs when they occur. Based on this rationale, we have offered LD Nivo to high-risk patients after careful clinical discussion. In this study, we present the outcomes of our institutional experience. **Methods:** This single institution, retrospective cohort study included patients with advanced skin cancers who received LD Nivo (40 mg) due to a high-risk of IRAEs, including those with a previous history of IRAEs from SD ICIs or ICI-naïve patients with pre-existing AID. We analyzed efficacy and safety endpoints, including best objective response rates (BORR) per RECIST v1.1 and rates of IRAE with SD and LD ICIs. Outcomes were analyzed using descriptive statistics and stratified Cox models. **Results:** From 2015 – 2025, 23 patients with advanced skin cancers (22-Melanoma; 1-Merkel cell carcinoma) received LD Nivo due to an elevated IRAE risk. Sixteen patients had a history of treatment-limiting IRAEs on SD ICIs ("Prior-IRAE" cohort: 7 SD anti-PD-1 monotherapy; 9 SD combination ICI), and 7 patients were ICI-naïve with pre-existing AID ("AID" cohort). In the Prior-IRAE cohort, treatment hold/discontinuation due to IRAEs occurred in 100% with SD ICI versus 43.8% with LD Nivo (p = 0.032). Among the 7 patients previously treated with SD anti-PD-1 monotherapy, the incidence of grade ≥2 IRAEs was 100% (median duration 75 days; range, 12–217) on SD therapy versus 42.8% (median duration 43 days; range, 23–146) on LD Nivo. In the AID cohort, 100% patients experienced at least one grade 2 IRAE, but no grade 3 or 4 events were observed. In patients with evaluable disease (measurable and progressing at LD Nivo initiation), BORR was 57.1% (4/7; 1 complete response [CR], 3 partial responses) in the Prior-IRAE cohort and 33.3% (2/6; both CR) in the AID cohort. **Conclusions:** LD Nivo demonstrates biological activity, as evidenced by both anti-tumor responses and toxicities, in patients at high risk of IRAEs. Compared to SD ICI, LD Nivo may offer an advantage in toxicity management, potentially enabling more consistent treatment delivery with fewer interruptions and reduced need for immunosuppressive interventions. This strategy warrants further evaluation in prospective clinical trials. Research Sponsor: Winn Career Development Award; Kuni Foundation.

Association of PCSK9 inhibitors with clinical outcomes in patients with cancer receiving immune checkpoint inhibitors: A real-world analysis. First Author: Chuan Angel Lu, UT Southwestern Medical Center, Dallas, TX

Background: Although developed as lipid-lowering agents, PCSK9 inhibitors (PCSK9i) have shown preclinical potential to synergize with immune checkpoint inhibitors (ICIs) by increasing tumor antigen presentation and overcoming ICI resistance. However, there is limited evidence describing their use and associated outcomes in real-world oncology practice. We aimed to explore the clinical outcomes in relation to PCSK9i use in patients with cancer receiving ICIs. **Methods:** This propensity score-matched (PSM) cohort study utilized the TriNetX research network, encompassing real-time electronic health records from > 70 U.S. healthcare organizations. The study population included adults (aged ≥18 years) diagnosed with non-small cell lung cancer, melanoma, renal cell carcinoma, or breast cancer, who underwent concurrent ICI therapy (e.g., pembrolizumab, nivolumab, atezolizumab, durvalumab) plus PCSK9i (e.g., evolocumab, alirocumab; with or without statins) or high-intensity statins alone (atorvastatin ≥ 40 mg, or rosuvastatin ≥ 20 mg) between 01/01/2011 (the earliest year of ICI approval) and 01/01/2025 for hyperlipidemia. The primary outcome was overall survival (OS). Secondary outcomes included emergency room (ER) visits, all-cause hospitalization, ICU admission, and 4-point (acute myocardial infarction, heart failure, stroke, and unstable angina) major adverse cardiovascular event (MACE). A 1:1 PSM was applied to balance potential confounders, including demographics, socioeconomic status, cancer site, Charlson-Comorbidity-Index comorbidities, and laboratory parameters [Albumin, LDL, AST/ALT, and BMI]. Time-to-event analyses were performed using Cox proportional hazards models to estimate hazard ratios (HRs) and 95% confidence intervals (CIs), with log-rank test for significant survival differences. Follow-up began at the initiation of concurrent ICI plus PCSK9i or statin and continued until 01/05/2025, or until the occurrence of the study outcomes. **Results:** A total of 254 patients in PCSK9i cohort were matched to 254 patients from the statin-only cohort (n = 13734). Patients receiving PCSK9i demonstrated significantly improved OS compared with those receiving statins alone (HR 0.67, 95% CI 0.52-0.88) and associated with lower risk of ER visits (HR 0.64, 95% CI 0.49-0.83), hospitalization (HR 0.68, 95% CI 0.54-0.85), and ICU admission (HR 0.69, 95% CI 0.50-0.95; all $p<0.01$). No significant difference was observed for MACE outcomes (HR 0.79, 95% CI 0.59-1.07, p=0.13). **Conclusions:** In this large, real-world analysis, the use of PCSK9i in patients with cancer and hyperlipidemia treated with ICIs was associated with improved overall survival and reduced healthcare utilization. These findings support ongoing prospective clinical trials evaluating the potential synergistic effects of PCSK9 inhibition with ICI therapy. Research Sponsor: None.

Modulation of PD-1 and PD-L1 expression on peripheral blood T-cells by novel rotavirus variants. First Author: Svetlana Yu Filippova, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation

Background: Promising oncolytic viruses are typically evaluated based on their direct cytotoxic effects on cancer cells. However, the therapeutic benefit of virotherapy may also stem from its immunomodulatory actions, particularly through influencing immune checkpoint molecules like PD-1 and PD-L1. This study aimed to investigate the effect of unclassified apathogenic rotavirus strains RVK100 and RVK228 on the expression of PD-1 and PD-L1 on T-cells derived from the peripheral blood of patients with breast cancer. **Methods:** Mononuclear cells of peripheral blood were isolated on a ficoll gradient, cultured in RPMI 1640 (Gibco, USA) without serum at 37 °C, 5.0% CO2 in 4 variants of the experiment: 1) negative control without viruses; 2) positive control of activation with the addition of PHA; 3) experience with the addition of 107 particles per 1 ml of the RVK100 strain; 4) experience with the addition of 107 particles per 1 ml of the RVK100 strain RVK228. After 24 and 72 hours of cultivation, the expression of PD-1 (CD279) and PD-L1 (CD274) was determined on T cells by flow cytometry. The study used antibodies conjugated with fluorochromes: anti-CD4 (PE), anti-CD8 (APC Cy7), anti-CD279 (FITC), anti-CD274 (PerCP-Cy5–5) (Becton Dickinson, USA). **Results:** After 24 hours, we observed increases in PD-1 expression on CD4+ (PHA—40.5%, RVK100—42.3%, RVK228—37.5%; vs. control—18.1%) and CD8+ cells (PHA—41.7%, RVK100—46.4%, RVK228—42.6%; vs. control—27.7%). Similarly, PD-L1 expression rose on CD4+ cells (RVK100—67.0%, RVK228—58.6%, PHA—75.1%; vs. control—44.8%) and CD8+ cells (RVK100—63.4%, RVK228—58.4%, PHA—52.8%; vs. control—46.2%). At 72 hours, PD-1 levels decreased significantly in CD4+ cells exposed to RVK100 (from 42.3% to 21.6%) and CD8+ cells (from 46.4% to 17.4%). Conversely, PD-L1 expression increased across all groups on CD8+ cells, reaching 67–79%, while minimal change occurred on CD4+ cells except for a minor decline in the RVK100 group. **Conclusions:** Both strains, like the non-specific T-mitogen PHA, caused the stimulation of the expression of immune checkpoint receptors PD-1 and PD-L1 on T-helpers and CTL after 24 hours of cultivation. After 72 hours of cultivation, RVK100, unlike RVK228, was revealed ability to reduce the expression of PD-1 on these cells. Research Sponsor: None.

Preclinical investigations and first-in-human phase I trial of KP-483 in solid tumors: Safety, antitumor activity, and preliminary efficacy. First Author: Noboru Yamamoto, Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan

Background: KP-483 is a novel small-molecule antagonist of the E-type prostanoid receptor 4 (EP4) that potentially exerts antitumor effects by modulating the tumor microenvironment and restoring antitumor immunity. Based on preclinical and phase I studies, this report presents the pharmacological properties, safety, and preliminary efficacy of KP-483. **Methods:** In preclinical studies, the pharmacodynamic profile of KP-483 was characterized *in vitro* and *in vivo*. Antitumor activity was evaluated in tumor-bearing mice, and tumor infiltrating $CD8^+$ and $CD163^+$ cells were quantified. A first-in-human phase I study (jRCT2031220311) using a 3+3 dose-escalation design enrolled patients with solid tumors who had progressed after standard treatments or for whom no appropriate standard treatment was available. KP-483 was administrated orally once daily, with dose escalation across five cohorts (50, 100, 200, 400, and 800 mg). The primary endpoints were dose-limiting toxicities (DLTs) and safety profiles. Plasma concentrations of KP-483 were also measured. Preliminary efficacy was evaluated according to RECIST criteria, and the antitumor mechanisms were explored by flow cytometry analysis of tumor tissue. **Results:** KP-483 exhibited greater EP4 antagonist activity than existing antagonists (IC_{50}: 1.0 nmol/L in human) and had higher binding affinity to the EP4 receptor and a longer dissociation half-life than PGE_2 *in vitro*. In mouse models, KP-483 exhibited dose-dependent antitumor effects following 14 days of oral administration at doses of 3, 30, and 300 mg/kg once daily. The number of $CD8^+$ T cells in tumor tissue increased while that of $CD163^+$ cells decreased in a dose-dependent manner. In addition, combination treatment with KP-483 (15 mg/kg, twice daily) and either anti-PD-1 or anti-PD-L1 antibodies enhanced antitumor effects compared with either monotherapy. In the phase I study, safety was assessed in a total of 19 patients. The median treatment duration was 43 days (range: 24–713 days), and no DLTs were observed. The most common treatment-emergent adverse events were anemia and nausea (each 26.3%), with only one study-drug-related grade ≥3 event (anemia). Systemic exposure to KP-483 increased with dose, and the plasma half-life of KP-483 ranged from 7.9 to 12.8 hours on treatment day 15. Best overall responses included stable disease in four patients and partial response in one patient. Flow cytometry analysis of tumor tissue showed a trend toward increased activated cytotoxic T cells, dendritic cells, and M1-like macrophages. **Conclusions:** KP-483 is a potent EP4 antagonist that exerts antitumor effects through modulation of the tumor immune microenvironment. Given its favorable safety and pharmacokinetic profiles, KP-483 represents a promising EP4 receptor–targeted therapeutic strategy with potential for combination with immune checkpoint inhibitors. Clinical trial information: jRCT2031220311. Research Sponsor: KAKEN Pharmaceutical Co., LTD.

Enrichment of the germline *NLRC5^{Pro191Leu}* variant in patients with immune checkpoint inhibitor–induced hepatitis. First Author: Shira Gabizon Peretz, Yale University School of Medicine, Medical Oncology, New Haven, CT

Background: Immune checkpoint inhibitor–induced hepatitis (ICI-hepatitis) is a clinically significant immune-related adverse event (irAE) that may require treatment interruption and immunosuppressive therapy. Predictors of susceptibility to irAEs remain poorly defined. NLRC5 is a key regulator of MHC class I antigen presentation and $CD8^+$ T-cell–mediated immune activation. We previously identified a germline missense variant at the NLRC5 gene (*$NLRC5^{Pro191Leu}$*) that is associated with ICI-related endocrinopathies, and increased expression of downstream genes involved in antigen presentation. Our purpose was to determine whether the variant has a broader role in immune-related toxicity. **Methods:** We evaluated the prevalence and clinical associations of the germline *$NLRC5^{Pro191Leu}$* variant in patients with grade ≥2 ICI-hepatitis. Sanger sequencing was performed to assess the *$NLRC5^{Pro191Leu}$* (rs74439742) germline variant. Hepatitis severity was graded according to CTCAE criteria. Clinical data included irAE co-occurrence, duration of corticosteroid therapy, and requirement for additional immunosuppression. Variant prevalence was compared with the general population using data from the 1000 Genomes Project. **Results:** Among 39 patients with ICI-hepatitis, the cohort was predominantly composed of patients with metastatic melanoma receiving ipilimumab plus nivolumab. The variant was significantly enriched in the ICI-hepatitis cohort compared with the general population (30.0% vs 12.8%; p = 0.007, odds ratio [OR] = 2.9). Variant carriers also more frequently developed co-occurring endocrine irAEs, particularly thyroid dysfunction and hypopituitarism. Conversely, co-occurrence of hepatitis and colitis was more frequent among wild-type patients (p = 0.06, OR = 7.6), suggesting distinct immunopathogenic toxicity patterns. The severity of hepatitis was assessed by a composite outcome of maximal grade 4 hepatitis and prolonged steroid use (≥120 days). Variant carriers showed a trend toward increased hepatitis severity that did not reach statistical significance (Fisher's exact p = 0.06; OR = 4.9). **Conclusions:** Germline *$NLRC5^{Pro191Leu}$* is significantly more common in patients who develop ICI-hepatitis than in the general population and is associated with distinct immune-related toxicity patterns. This suggests that host genetic factors may inform toxicity surveillance and early management strategies. Larger multi-center studies are needed to validate these observations and define the clinical utility of *$NLRC5^{Pro191Leu}$* as a predictor of immune-related toxicity risk. Research Sponsor: Davidoff Fund.

Prevalence of *$NLRC5^{Pro191Leu}$* variant in the ICI-hepatitis cohort.

Group	NLRC5 WT, n (%)	*NLRC5Pro191Leu*, n (%)
ICI-hepatitis cohort (n=39)	27 (70.0)	12 (30.0)
Odds ratio		2.9
p value		0.007
General population (1000 Genomes Project) (n=694)	605 (87.2)	89 (12.8)

Systemic third generation allosteric STING agonist CRD3874-SI, a novel immunotherapy, in patients with advanced solid tumors: Results from a single-agent phase I study. First Author: Ciara M. Kelly, Memorial Sloan Kettering Cancer Center, New York, NY

Background: CRD3874-SI is a first in class, systemically administered, allosteric STING agonist that blocks STING's proton channel activity differentiating it from previously developed STING agonists. The drug has demonstrated pre-clinical anti-cancer activity in several murine tumor models and has pharmacological properties distinct from earlier generation STING agonists. **Methods:** This is a single institution, open-label, phase I study of CRD3874-SI in patients with advanced solid tumors. The dose escalation study follows a standard 3+3 design. CRD3874-SI is administered intravenously once per week for 2 cycles. Cycle duration is 28 days. From cycle 3 onwards, continuous weekly treatment +/- one week break (week 4) may be considered. The primary objective is to assess the safety of CRD3874-SI by determining the maximum tolerated dose, recommended phase 2 dose and schedule of administration. Secondary objectives include examining the pharmacokinetics and pharmacodynamics (IP10 analysis) of CRD3874-SI and evaluating the efficacy of CRD3874-SI as determined by best objective response rate per RECIST v 1.1. Clinical trial information: NCT06021626. Research sponsor: Curadev Pharma, Inc. **Results:** As of January 5th 2026, 21 patients (sarcoma n=20, adenoid cystic carcinoma n=1) received treatment at four escalating dose levels (0.1-1.8mg/kg). The median number of prior lines of treatment was 4 (1-11). The median duration of treatment was 7 weeks (range: 1-32 weeks). 2 patients continue treatment. Reasons for treatment discontinuation include: progression of disease (n=16), toxicity (n=2), patient withdrawal (n=1). Treatment emergent adverse events (TEAEs) were manageable and reversible. Only low-grade cytokine related symptoms were reported. TEAEs possibly related to study treatment reported in $>$20% of participants and were mostly low grade include: fatigue (43%), chills (38%), nausea (38%), diarrhea (33% (G3 (10%)), headache (29%) and flu-like symptoms (24%). Low grade colitis not typical of auto-immune mechanism, responding well to temporary treatment pause +/- oral budesonide, were reported in 4 patients. One DLT at dose level 4 (G3 dyspnea) was observed. 19 patients are evaluable for efficacy. The best objective response per RECIST v1.1: confirmed partial response, n=1 (malignant phyllodes tumor); stable disease, n=9; progressive disease, n=9. Dose level 3 (0.9mg/kg) represents a biologically active dose (one confirmed PR and a second case with -27% tumor regression was observed). Dose proportional increase in AUC with concomitant increase in plasma CXCL10 levels were observed. **Conclusions:** CRD-3874-SI has demonstrated clinical activity with manageable safety. Dose level 0.9mg/kg is biologically and clinically active. A dose expansion phase at this dose level in is planned in $>$5 histology specific cohorts. Clinical trial information: NCT06021626. Research Sponsor: Curadev Pharma.

2662 **Poster Session**

Effect of IL7 on ImmTAC-mediated killing by T cells in vitro and T-cell fitness in patients. First Author: Joseph J. Sacco, The Clatterbridge Cancer Centre and University of Liverpool, Liverpool, United Kingdom

Background: A blood T cell fitness (TCF) signature, reflecting properties of naïve and stem cell memory T cells, was strongly associated with clinical benefit from tebentafusp (gp100 $\times$ CD3) and brenetafusp (PRAME $\times$ CD3) ImmTAC bispecific therapies[1]. Here, we assessed whether TCF could be enhanced by IL7, a cytokine that plays a key role in T cell homeostasis and promotes the proliferation and survival of naïve and stem cell memory T cells. **Methods:** T cell exhaustion was induced in vitro by four weekly ImmTAC stimulations against the Non-Small Cell Lung Cancer (NSCLC) cell line NCIH1755 with or without IL7. Tumor killing, T cell cytokine secretion, and T cell phenotype were assessed using standard methods. Data are given as mean $\pm$ SEM; groups were compared using paired t test. *IL7R* gene expression and TCF (mean expression of *TESPA1*, *CD28* and *GPR183*) were measured in baseline whole blood from patients with unresectable or metastatic uveal melanoma (mUM) treated with tebentafusp (n=132 NCT02570308) or brenetafusp (N=37 NCT04262466) as previously described[1]. TCF high/low threshold was cut at the median. TCF was also assessed in baseline and on-treatment PBMC from patients with NSCLC and Triple-Negative Breast Cancer (TNBC) (n=15) receiving NTI7, a long acting recombinant human IL7 (rhIL7, NCT03752723, NCT04984811). **Results:** In vitro, repeated re-direction of T cells by ImmTAC resulted in reduced tumor cell lysis from 46$\pm$9% after a single stimulation to 3$\pm$1% after 4 weekly stimulations. In contrast, T cells cultured with IL7 retained tumor cell lysis after 4 stimulations (58$\pm$2% ImmTAC-redirected cytolysis compared with 3$\pm$1% in IL7-untreated T cells, p = 0.02), accompanied by a 14.3-fold increase in IFNγ secretion (p = 0.04). The proportion of naïve/stem cell memory T cells increased in response to IL7 treatment from 37$\pm$5% to 57$\pm$8% (p=0.009). In mUM patients, gene expression of *IL7R* strongly correlated with TCF signature in peripheral blood (R = 0.91, p $<$ 0.001). As early as 3 weeks following a single dose of NTI7, TCF increased by ~3-fold in PBMC from NSCLC and TNBC patients. The proportion of TCF high patients increased from 36% at baseline to 93% post NTI7 monotherapy. This increase in TCF signature was sustained for at least 12 weeks. **Conclusions:** Despite repeated antigen stimulation in vitro, IL7 sustained naïve/memory T cells, enhanced ImmTAC-redirected T cell cytotoxicity and IFNγ production, and reduced T cell exhaustion. A single dose of rhIL7 resulted in a sustained increase in TCF signature and converted patients with low TCF signature into high TCF. These findings support combination with IL7 as a rational strategy to augment T cell fitness and potentially improve efficacy of ImmTAC bispecific T cell therapies. 1) Sacco et al ESMO 2024. Research Sponsor: Immunocore Ltd.

A phase I study of pomalidomide and nivolumab (Pom/Nivo) in patients with virus-associated malignancies with and without HIV. First Author: Jose Mercado-Matos, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Up to 15% of cancers worldwide are associated with oncogenic viruses and disproportionately affect people with HIV (PWH). Epstein–Barr virus (EBV) is linked to several malignancies, particularly lymphomas; Kaposi sarcoma herpesvirus (KSHV) to Kaposi sarcoma (KS) and primary effusion lymphoma (PEL); and human papillomavirus (HPV) to anogenital and head and neck cancers. Virus-associated tumors evade immune surveillance through mechanisms such as T-cell exhaustion. In vitro studies show that pomalidomide (Pom), an immunomodulatory drug, enhances T-cell co-stimulation and increases immune surface marker expression in virus-infected cell lines. Pom may synergize with nivolumab (Nivo), an anti-PD-1 monoclonal antibody, to reverse immune exhaustion and enhance antitumor immunity. **Methods:** This phase I study enrolled participants (pts) with advanced virus-associated malignancies (EBV, KSHV, HPV). PWH were required to receive antiretroviral therapy for $\geq$4 weeks with an HIV viral load (VL) $\leq$400 copies/mL. There was no CD4 T-cell requirement; however, major opportunistic infections (with limited exceptions) were not permitted within 6 months of enrollment. Intravenous Nivo (480 mg) was administered every 28 days with Pom given once daily on days 1-21 of a 28-day cycle using a 3+3 dose-escalation design (DL1=3 mg, DL2=4 mg, optional DL-1=2 mg) for up to 24 cycles. The primary objective was safety and tolerability of the combination (using CTCAE v5.0). The secondary objective was to evaluate the anti-tumor activity of Pom/Nivo using disease-specific criteria (RECIST 1.1, Lugano criteria, or modified ACTG criteria for KS). **Results:** Sixteen pts (75% male, 56% White and 37% Hispanic) were enrolled, including 9 PWH with a baseline median (med) CD4 T-cell of 253 cells/mm^3 (range 61-616) and HIV VL 37 copies/mL. After a med of 7 cycles (range 1-24), the most common Grade (G) 1/2 toxicities were anemia, lymphopenia, and maculopapular rash. Five pts had G3 or G4 neutropenia that was managed with growth factor support and Pom dose reductions. The only dose-limiting toxicity was observed in 1 pt with metastatic anal cancer in DL1 who developed G3 dyspnea; the maximum tolerated dose of Pom was 4 mg. Five pts were not evaluable for an objective response (2 died from progressive disease (PD), 2 declined further treatment, 1 was deemed ineligible), among 11 pts who received $\geq$3 cycles, all 4 pts with KS had a response (2 partial and 2 complete responses), 1 pt with PEL had stable disease (SD), 1 of 4 pts with HPV-malignancies had SD and 1 of 2 with nasopharyngeal carcinoma had SD, and 4 pts had PD. Among PWH, CD4 T-cell count did not change from baseline to the end-of-treatment (p=0.46). **Conclusions:** Pom/Nivo is a chemotherapy-sparing regimen with acceptable safety in advanced virus-associated cancers and promising activity in KS. Based on these results, an expanded KS cohort will be added to the trial. Clinical trial information: NCT04902443. Research Sponsor: None.

2664 **Poster Session**

Influence of pelareorep on mutant KRAS-specific blood TIL clonal expansion. First Author: Richard Trauger, Oncolytics, San Diego, CA

Background: Pelareorep (pela) is an intravenously delivered unmodified oncolytic reovirus that selectively infects cancer cells and is being developed as an immunotherapy for multiple cancers. We report here the analysis of tumor and blood samples from breast and pancreatic cancer patients that demonstrate a multi-step process of innate, viral, and tumor-specific immune activation culminating in the expansion of tumor-specific mutant KRAS (mKRAS) T cell clones that are associated with reductions in tumor volume. **Methods:** Translational samples were obtained from subjects enrolled in breast cancer (AWARE-1 ClinicalTrials.gov ID NCT04102618) and pancreatic (PDAC) cancer trials (GOBLET ClinicalTrials.gov ID NCT07280377). Analysis of tumor gene expression was performed on extracted RNA from Formalin-Fixed Paraffin-Embedded (FFPE) obtained from AWARE-1 clinical samples collected at baseline, day 3 and day 21 of therapy. Changes in tumor gene expression were determined using a customized code-set including the 50 PAM50 genes + other genes (as immune panels). Translational data from GOBLET PDAC subjects included anti-reovirus T cell responses, which were assessed by ELISPOT using whole inactivated reovirus antigen stimulation. Enumeration of the T cell fractions was performed by Adaptive Biotechnologies (Seattle, WA, USA). TCRβ CDR3 DNA was isolated from tissue and blood at baseline and from blood collected post-treatment from both studies. Antigenic specificity of selected T cell clones for mKRAS was determined by the MIRA assay (Adaptive Biotechnologies). **Results:** Sequential genetic analyses of breast cancer tumor biopsies pre- and post-pelareorep therapy demonstrated significant increases in anti-viral and immune gene expression consistent with the activation of toll-like receptor 3 (TLR3). Activation of TLR3 also induced the production of CXCL13, a chemokine critical for the formation of tertiary lymphoid structures (TLS). TLS in the tumor were confirmed by imaging mass cytometry of tumor biopsies following pelareorep treatment. Expansion of tumor-infiltrating lymphocytes (TILs) in both tumor and blood was also observed. Analysis of serial blood samples from a cohort of pelareorep-treated pancreatic cancer patients showed expansion of anti-viral T cells by ELISPOT. In addition, clonal expansion of tumor-specific T cells was observed after one cycle of treatment. The expansion of pre-existing TIL clones in the blood correlated with reductions in tumor volume in pancreatic cancer. Analysis of TCR sequences for antigen specificity confirmed the expansion of mKRAS clones in these samples. **Conclusions:** These findings suggest that pelareorep immunotherapy, through the combined activation of TLR3 and infection of the tumor, induces innate and adaptive antiviral and anti-tumor-specific immune responses capable of controlling tumor growth. Research Sponsor: None.

TPS2665 **Poster Session**

ASP2998, a trophoblast cell-surface antigen 2 (TROP2)–targeted immunostimulatory antibody-drug conjugate with dual payloads, in patients with locally advanced unresectable or metastatic solid tumors: A phase 1b/2 study. First Author: Guru P. Sonpavde, AdventHealth Cancer Institute and the University of Central Florida, Orlando, FL

Background: TROP2 is a type I transmembrane glycoprotein involved in cell proliferation, migration, and survival, that is upregulated in and is associated with poor prognosis in patients (pts) with several malignancies including urothelial carcinoma, non-small cell lung cancer, gastric cancer and breast cancer. TROP2 antibody drug conjugates (ADCs) have demonstrated clinical efficacy and are approved for metastatic breast cancer and epidermal growth factor receptor-mutated non-small cell lung cancer. ASP2998 is a dual-payload (topoisomerase I inhibitor plus stimulator of interferon genes [STING] agonist) immunostimulatory ADC targeting TROP2. ASP2998 monotherapy has shown preclinical antitumor activity in a syngeneic mouse model bearing human TROP2-expressing tumors that was superior to single-payload topoisomerase I inhibitor TROP2 ADCs. **Methods:** This first-in-human, multicenter, open-label, phase 1b/2 dose escalation (DESC) and expansion (DEXP) study, is evaluating the safety, tolerability, recommended phase 2 dose (RP2D) and/or maximum tolerated dose (MTD), preliminary antitumor activity, and pharmacokinetic profile of ASP2998 in pts with locally advanced unresectable or metastatic solid tumors. Initial DESC of ASP2998 includes 6 dose levels (n≥3 per dose level) to determine the RP2D and/or MTD. Eligible pts (aged ≥18 years) include those with urothelial carcinoma, non-small cell lung cancer, gastric/gastroesophageal junction cancer, or locally confirmed human epidermal growth factor receptor 2-negative breast cancer, who have progressed on, are ineligible for, or have refused all available standard therapies per investigator's decision. At DEXP, multiple dose levels of ASP2998 may be evaluated based on the totality of data to optimize dosage in at least one tumor type (n≤40 per dose level per tumor type). Eligible DEXP pts with non-small cell lung include those who have received ≤3 prior lines of therapy and known programmed death-ligand 1 status, without actionable oncogenic alterations, who have progressed on or after platinum-based chemotherapy and/or checkpoint inhibitors. Eligible DEXP pts with urothelial carcinoma include those who have received ≤3 prior lines of therapy and progressed on or after enfortumab vedotin plus pembrolizumab. Prior exposure to TROP2, STING agonists or topoisomerase I inhibitor-directed therapy is permitted at DESC but not DEXP. Tumor-specific backfill pts can be enrolled in the DESC cohorts at dose levels that are deemed safe and tolerable, and will be counted towards the corresponding tumor-specific DEXP cohorts. Recruitment is ongoing with 196 planned pts (36 in DESC; 160 in DEXP). ClinicalTrials.Gov Identifier: NCT07287995. Clinical trial information: NCT07287995. Research Sponsor: Astellas Pharma Inc.

TPS2666 **Poster Session**

Phase I/II study of AZD6750, a CD8-guided interleukin-2 agent, alone and in combination with other anti-cancer agents in participants with advanced or metastatic solid tumors. First Author: Drew W. Rasco, South Texas Accelerated Research Therapeutics (START), San Antonio, TX

Background: Interleukin-2 (IL-2) has antitumor activity through stimulation of proliferation and differentiation of cytotoxic T lymphocytes, but toxicity due to systemic immune system activation limits its clinical use. AZD6750 comprises two CD8 human IgG1 binding domains and two IL-2 mutein domains and uses cis-guiding to deliver IL-2 mutein preferentially to CD8+ T cells, with the goal of increasing antitumor activity while limiting toxicity. It has high affinity for CD8α and the CD122/CD132 IL-2R complex, and reduced affinity for CD25 (IL-2Rα). In preclinical studies, AZD6750 has been shown to cause preferential proliferation of CD8+ T cells without increasing cytokine release from peripheral blood mononuclear cells; improve antigen-specific tumor cytolysis; increase IFN-γ secretion, a sign of productive responses in tumor-infiltrating lymphocytes; and inhibit growth of a tumor model in vivo. We describe the design of a phase I/II trial of AZD6750 in patients with metastatic solid tumors (NCT07115043). **Methods:** This first-in-human, open-label, phase I/II, multicenter clinical trial is evaluating AZD6750 as monotherapy (Module 1, dose escalation) and combined with rilvegostomig (Module 2) in patients with selected locally advanced or metastatic solid tumors. All patients must have ECOG performance status of 0/1 and ≥1 measurable lesion per RECIST v1.1. In Module 1, patients must have received prior standard-of-care therapy and have a tumor type for which immune checkpoint inhibitors are known to be effective or in which IL-2 potentially has benefit. Dose escalation starts with an accelerated titration design and switches to a modified toxicity probability interval-2 (MTPI-2) design after the first 2 dose cohorts or earlier sign of grade ≥2 toxicity. Module 2 will enroll patients with stage IV NSCLC who have either received ≥1 line of therapy in the metastatic setting (including targeted therapy if actionable mutations are present) (Module 2A, dose escalation) or are metastatic treatment naïve and have tumor PD-L1 expression ≥1% (Modules 2A and 2B). Patients who have autoimmune or inflammatory disorders within 3 years of study or toxicity that led to discontinuation of prior immunotherapy are not eligible for Module 2. In Module 2A, dose escalation will use MTPI-2. Module 2B will be a dose expansion module. The primary endpoints of Modules 1 and 2A are the incidence of adverse events (AEs), serious AEs, and dose-limiting toxicities, which will be used to determine the maximum tolerated dose/recommended phase 2 dose. In Module 2B (dose expansion), the primary endpoint will be preliminary antitumor activity. Secondary endpoints include pharmacodynamics (PD-L1), immunogenicity (anti-drug antibodies), and pharmacokinetics. The study is actively recruiting globally, with 3 patients enrolled as of December 2025. Clinical trial information: NCT07115043. Research Sponsor: AstraZeneca.

TPS2667 **Poster Session**

A phase I trial evaluating an optimized B7-H3xCD3 T cell engager for treatment of solid cancer. First Author: Jonas S. Heitmann, Clinical Collaboration Unit Translational Immunology, Department of Internal Medicine, Cluster of Excellence iFIT (EXC2180), University Hospital Tübingen, Tübingen, Germany

Background: T cell-based immunotherapy has revolutionized oncological treatment of various malignancies. However, many patients still do not respond to immunotherapy, and long-term remissions remain rare, particularly in solid tumors. B7-H3 (CD276) is overexpressed in multiple cancer entities on both tumor cells and tumor microenvironment, the latter facilitating access of effector cells into the tumor site as prerequisite for success of therapeutically targeting solid cancers. To address the high medical need of patients with colorectal cancer (CRC), breast cancer (BC), penile cancer as well as bone and soft tissue sarcoma, we developed and validated a CD276xCD3 T cell engager (TCE) termed CC-3. CC-3 mediated pronounced antitumor activity in vitro and displayed the expected long half-life and potent antitumor activity in murine models using immunocompromised mice adoptively transferred with human effector cells with regard to prevention of lung metastasis and flank tumor growth as well as elimination of large established tumors (Zekri et al, Mol Ther, 2023). **Methods:** This is an ongoing open label, multi-center phase I clinical trial evaluating CC-3 in patients with metastatic CRC, BC, penile cancer as well as bone and soft tissue sarcoma. Key eligibility criteria include diagnosis of progressive metastatic disease and exhaustion of standard of care. The trial comprises a dose escalation part to determine the maximum tolerated dose followed by a dose expansion part to define the recommended phase II dose and collect first signs of efficacy. During the dose escalation, initially an accelerated titration design with single patient cohorts is employed. Here, each patient receives a fixed dose level (starting with 50μg for the first patient). Dose levels are increased by up to 100%, based on the decision of a safety review committee (SRC). Upon occurrence of adverse events (AEs) grade ≥2, dose limiting toxicity (DLT), or reaching a dose level of ≥800μg, treatment switches to a standard 3+3 dose escalation design. After maximum tolerated dose (MTD) is determined, defined as no more than one of six patients experiencing DLT, an additional 14 patients receive CC-3 at the MTD level in the dose expansion phase. Primary endpoints are incidence and severity of AEs, as well as the best objective response to treatment according to RECIST 1.1. Secondary endpoints include overall safety, efficacy, survival, quality of life, and pharmacokinetic investigations. At present, the accelerated titration phase employing cohorts 1 - 4 has been completed without DLT; likewise, in the so far completed cohorts 5-8 of the standard titration phase, no DLT was observed. Enrollment to cohort 9 began in May 2025. Clinical trial information: NCT05999396. Clinical trial information: 2022-503084-15-00. Research Sponsor: German Cancer Consortium (DKTK).

TPS2668 **Poster Session**

First-in-human phase 1a/1b study of LB-LR1109, an anti-LILRB1 monoclonal antibody, as monotherapy in advanced solid tumors and in combination with atezolizumab in advanced NSCLC. First Author: Hyungjin Cho, LG Chem Lifescience USA, Boston, MA

Background: LB-LR1109 is a human IgG4 monoclonal antibody targeting LILRB1, an inhibitory receptor expressed on multiple immune cell subsets. LILRB1 binds HLA-G, delivering suppressive signals that enable tumor immune evasion. Blocking this axis may restore immune activation within the tumor microenvironment and promote both innate and adaptive anti-tumor responses. Phase 1a tumor types were selected through TCGA analyses showing high LILRB1/HLA-G expression and increased infiltration of LILRB1+ NK cells, T cells, and monocytes in RCC, NSCLC, HNSCC, urothelial carcinoma (UC), and melanoma. High LILRB1 expression correlates with poor overall survival in RCC, UC, and lung SCC, supporting clinical relevance. Preclinical data (AACR2026 #1243) demonstrated that LB-LR1109 binds LILRB1 with high affinity, blocks HLA-G interactions, restores NK and T-cell function, and induces strong anti-tumor activity in human LILRB1 transgenic mouse models. LB-LR1109 also showed synergy with PD-L1 blockade, favorable PK, and an excellent safety profile, supporting clinical development as monotherapy and in combination. Public transcriptomic data also support combining LB-LR1109 with atezolizumab in NSCLC based on correlated LILRB1 and PD-L1 expression. **Methods:** This ongoing first-in-human, multicenter, open-label Phase 1 study (NCT06332755) evaluates LB-LR1109 as monotherapy (Phase 1a) and in combination with atezolizumab (Phase 1b). The study began in September 2023; Phase 1b enrollment started December 2025. Phase 1a includes monotherapy dose escalation (DL1–DL8, IV Q2W) using BLRM, enrolling patients with advanced/metastatic RCC, NSCLC, HNSCC, UC, or melanoma who relapsed from or are intolerant to approved therapies. Phase 1b evaluates LB-LR1109 (IV Q2W) plus atezolizumab 840 mg Q2W in advanced/metastatic NSCLC without actionable mutations. Patients must have received prior approved therapies including anti-PD-1/PD-L1 with ≥12 weeks of response, to test whether LILRB1 blockade may restore immune surveillance after checkpoint inhibitor resistance. Primary objectives: safety, tolerability, and determination of MTD/RP2D. Secondary endpoints: antitumor activity, PK, immunogenicity. Exploratory endpoints: correlations between LILRB1/HLA-G expression and clinical response, longitudinal immune profiling, and receptor occupancy in peripheral monocytes. The study is conducted at eight sites in Korea and the United States. Phase 1a has escalated to DL7 with no DLTs, and enrollment into the combination DL5 cohort began January 2026. Clinical trial information: NCT06332755. Research Sponsor: LG Chem Lifescienes.

TPS2669 **Poster Session**

Phase 1 first-in-human trial of AG01, a recombinant humanized monoclonal antibody to progranulin/glycoprotein 88 (GP88) to determine the safety, tolerability, pharmacokinetics, and preliminary antitumor activity in subjects with advanced solid tumor malignancies. First Author: Katherine H.R. Tkaczuk, University of Maryland School of Medicine & Marlene and Stewart Greenebaum Comprehensive Cancer Center, Baltimore, MD

Background: Progranulin also called GP88/PGRN plays a major role as an autocrine growth & survival factor associated with resistance to standard of care (SOC) targeted and chemo therapies in several cancers including breast cancer (BC) & non-small cell lung carcinoma (NSCLC): 1) GP88 is expressed in 80% breast invasive ductal carcinomas & is negative in normal mammary tissue; 2) GP88 tumor expression is a prognostic indicator of recurrence & survival in BC, NSCLC & prostate cancer patients (pts) 4) Elevated serum GP88 levels are present in several cancers including metastatic breast cancer (MBC), lung & prostate cancer pts compared to healthy subjects; 5) Elevated/rising GP88 serum levels in MBC pts are associated with disease progression & inferior survival. These results make GP88 an ideal therapeutic & diagnostic target in solid tumors. An anti-human PGRN/GP88 monoclonal antibody inhibiting PGRN/GP88 action was developed & expressed in CHO cells. Pharmacology, GMP manufacturing, formulation, stability studies & GLP toxicology studies in non-human primates were done. The IND application cleared by the US FDA led to the FIH AG01 study in adults with advanced solid tumors lacking effective therapies. **Methods:** A Phase 1 FIH dose-escalation study was designed in pts with advanced solid tumor malignancies, the study is approved by the University of Maryland IRB. AG01 monoclonal antibody is administered intravenously (IV) over 90 minutes every 14 days +/- 1 day; DLT observation period is the 1st cycle=28days, with AG01 Dose levels of,1mg/kg, 2mg/kg, 4mg/kg, 6mg/kg, 8 mg/kg. Initially accelerated titration design (1pt/dose level) was followed by 3+3 design). Eligibility criteria include pathologically confirmed diagnosis of advanced/relapsed/refractory solid tumor malignancy; failed $>$=1 SOC therapy or not a candidate/declines SOC therapy, ECOG $<$=2, adequate organ/bone marrow function, at least 1 RECIST 1.1 measurable and/or evaluable lesion. Tumor imaging-every 2 cycles (8 weeks) is used for response assessment. Primary objective is to determine the maximum tolerated dose MTD and/or maximum administered dose MAD of AG01 in the target population. Secondary objectives are to determine the RP2D, safety, tolerability, PKs, immunogenicity (ADA) & the preliminary anti-tumor activity of AG01 in pts with advanced solid tumors. Exploratory objectives will determine PGRN/GP88 expression in tumor tissue & PGRN/ GP88 blood levels (A&G's IHC & ELISA test). The study is ongoing; & pts are currently enrolled. A parallel prospective study investigates the association of serum GP88 in MBC pts with response to SOC therapy and progression of disease based on RECIST 1.1 criteria. These studies are supported by NCI grants R44CA224718 and CA210817. Clinical trial information: NCT05627960. Research Sponsor: None.

TPS2670 **Poster Session**

A first-in-human phase I clinical trial evaluating the safety, tolerability, and preliminary efficacy of the novel fas ligand (FasL) inhibitor M3T01 in adults with advanced solid tumors. First Author: Rom S. Leidner, Earle A. Chiles Research Institute, Providence Cancer Institute, Portland, OR

Background: Tumor-specific T cells undergo apoptotic cell death following FasL binding to the fas (CD95) receptor. FasL is upregulated in many advanced cancers and is expressed by tumor endothelial cells, macrophages, and activated T and natural killer (NK) cells. Consequently, FasL contributes to tumor progression through deletion of tumor-specific T cells and impaired T cell tumor infiltration. Preclinical studies demonstrate that FasL blockade facilitates increased T cell tumor infiltration and enhances efficacy of immune checkpoint inhibitors and adoptive cell therapies. M3T01 is a fully human IgG4/kappa monoclonal antibody that potently inhibits FasL. This is an ongoing first-in-human phase I clinical trial (NCT06719362) evaluating the safety, tolerability and preliminary antitumor efficacy of M3T01 as monotherapy and in combination with pembrolizumab in adults with advanced solid tumors. **Methods:** The primary objectives are to evaluate the safety/tolerability, dose-limiting toxicity (DLT), and maximum tolerated dose (MTD) of M3T01. Secondary objectives are to characterize the pharmacokinetics, pharmacodynamics, immunogenicity, and preliminary antitumor efficacy of M3T01 as monotherapy and in combination with pembrolizumab. A sub-study will evaluate paired tumor biopsies (pre-treatment and cycle 2 day 8) to evaluate for changes in the tumor microenvironment induced by FasL inhibition. Eligible patients have unresectable or metastatic solid tumors that are refractory to standard systemic therapy. Patients must have adequate organ function, measureable disease per RECIST v1.1 or RANO 2.0, and an ECOG performance status of 0-1. Dose escalation through a 3 + 3 design will evaluate M3T01 as monotherapy and in combination with pembrolizumab (administered intravenously every 3 weeks). Monotherapy cohorts 1-4 (100 to 600 mg) have been completed without DLT. After completion of the dose escalation portion of the trial, dose expansion cohorts will open to evaluate M3T01 in combination with standard systemic therapies in the treatment of patients with glioblastoma, gastric/esophageal adenocarcinoma, and head and neck squamous cell carcinoma. Clinical trial information: NCT06719362. Research Sponsor: None.

TPS2671 **Poster Session**

A phase I/IIa dose-escalation, dose-optimization, and dose-expansion study to evaluate the safety and preliminary efficacy of tri-specific antibody (SOA101) in subjects with advanced solid tumors. First Author: Jennifer Ho, Shine-On Biomedical, Taichung, Taiwan

Background: SOA101 is a nanobody (VHH)-based tri-specific T cell engager targeting programmed death-ligand 1 (PD-L1), Human Leukocyte Antigen G (HLA-G), and Cluster of Differentiation 3 (CD3) to modulate the immunosuppressive tumor microenvironment and enhance T-cell activation and recruitment. In vitro, SOA101 showed potent, broad-spectrum anti-tumor activity, enhancing peripheral blood mononuclear cells mediated cytotoxicity against non–small cell lung cancer (NSCLC) cells with varying PD-L1/HLA-G expression. In vivo, SOA101 demonstrated superior anti-cancer efficacy compared with relevant monoclonal antibodies and bispecific T-cell engagers in a humanized NSCLC mouse model, achieving effective tumor control and prolonged survival. The pharmacologically active dose did not increase cytokine secretion ex vivo, indicating a manageable safety profile with low cytokine release syndrome risk. **Methods:** This first-in-human clinical study, regulated by FDA and TFDA, is being conducted in subjects with locally advanced or metastatic solid tumors, including NSCLC ovarian cancer, head and neck cancer, breast cancer, and colorectal cancer with PD-L1 expression $\geq$1%. The dose-escalation phase is a six-cohort study designed to determine the maximum tolerated dose or pharmacoactive dose, enrolling up to 36 subjects who receive bi-weekly SOA101 for up to six doses. The dose-optimization phase randomizes approximately 40 subjects into low- or high-dose cohorts to further evaluate safety, pharmacokinetics, preliminary antitumor activity, and to determine the recommended Phase 2 dose. Part 2 may include up to four disease-specific expansion cohorts (up to 27 subjects each) to further characterize safety and antitumor activity. The study is currently in the dose-escalation phase. Cohort 1 has been completed without DLT, and enrollment for Cohort 2 has begun following approval by the independent Safety Review Committee. Clinical Trial Registry Number: NCT07055594. Clinical trial information: NCT07055594. Research Sponsor: None.

TPS2672 **Poster Session**

Phase 1, open-label clinical trial to treat stage IV cancer patients harboring multiple patient-specific mutated cell surface proteins with chimeric antibodies. First Author: Monika Joshi, Penn State Cancer Institute, Hershey, PA

Background: Despite the advent of multiple classes of systemic cancer treatments, tumor recurrence and subsequent resistance to systemic therapy remain a persistent challenge. Thus, newer treatment strategies are needed for metastatic cancer refractory to extant therapies. Leveraging the vast landscape of targetable tumor-specific mutated peptides (TSPs) on the surface of malignant cells offers an opportunity for individualized antibody therapy. These surface TSPs arise due to genetic instability and progressive accumulation of random missense mutations in cancer cells, resulting in dozens to hundreds of substituted amino acids in proteins at the cancer cell surface. We refer to surface proteins harboring substituted amino acids as Mutated cell Surface Proteins (MSPs). Antibodies generated against short TSPs preferentially bind to the mutated peptide compared to the nonmutated peptide. Notably, most cancers harbor several distinct MSPs. For instance, of 100 colon cancer cases, 96% harbored $\geq$10 MSPs, with similar findings in lung cancer (97%), melanoma (93%), lymphoma (92%), bladder cancer (85%), and stomach cancer (84%). While the presence of many MSPs is common, each patient harbors a unique set of MSPs. Study sponsor has developed a means of preparing custom antibodies against the TSPs present in multiple MSPs to inhibit cancer growth in several preclinical models, prompting a pan-tumor Phase I study evaluating the safety and feasibility of such therapy in refractory cancer patients. **Methods:** This is a phase I first-in-human study aiming to enroll up to 12 eligible subjects. Primary objective: Safety and tolerability. Secondary objectives: Feasibility of producing and administering the protocol-directed treatment to the patient population; progression-free survival; response rate. Key Inclusion Criteria: a) Stage IV refractory cancer (breast, colon, esophageal, kidney, lung, ovarian, bladder urothelial, stomach, or pancreatic cancers, melanoma, or lymphoma); b) availability of tumor and matched normal tissue sequence data. Treatment: Custom-manufactured chimeric antibodies are being used to target a minimum of 2 to 8 MSPs per patient. An interval of 4- to 6-month antibody production interval is required from initial consent to the start of treatment. The dose-limiting toxicity (DLT) period is 4 weeks; thereafter, in addition to antibody treatment, subjects can receive standard of care [immunotherapy, targeted therapy or hormonal therapies]. Treatment schedule: Week 1, 100 mg i.v.; week 2, 200 mg i.v.; week 3 400 mg; and then 400 mg i.v. every other week for total of 10 doses. We have enrolled 3 subjects and have completed treatment of Subject #1 (bladder cancer), with no DLT to date. The study is ongoing since 12/2025. Clinical trial information: NCT06674538. Research Sponsor: Moonshot Antibodies, Inc.

TPS2673 **Poster Session**

A logic-gated chimeric antigen receptor T-cell (CAR T) therapy with an armored, membrane-tethered IL-12 booster in patients with advanced solid tumors with HLA-A*02 loss of heterozygosity (LOH): EVEREST-2, a phase 1/2 study. First Author: Salman Rafi Punekar, NYU School of Medicine, New York, NY

Background: The main challenge for developing CAR T therapies for solid tumors is the lack of targets that distinguish tumor from normal cells, resulting in on-target, off-tumor toxicity. Tmod logic-gated CAR T therapy addresses this challenge by incorporating 2 CARs on the same T cell: an activator targeting a marker on both tumor and normal cells, and a blocker targeting HLA-A*02 that inhibits CAR T activity against normal cells while allowing activation against tumor cells (with HLA-A*02 LOH), improving tumor selectivity and decreasing toxicity. Early safety results from 3 ongoing phase 1/2 clinical trials of logic-gated, Tmod CAR T therapy (EVEREST-1, EVEREST-2, and DENALI-1) have demonstrated manageable safety and tolerability in patients with advanced solid tumors (Grierson et al, *SITC*, 2024; Ward et al, *SITC* 2025; Specht et al, *SABCS*, 2025). Early efficacy results include the first ever reported complete response in a patient with non-small cell lung cancer following treatment with a CAR T-cell therapy (A2B694). A2B543 is an autologous Tmod CAR T therapy that contains the same Tmod construct as A2B694 with an added membrane-tethered IL-12 (memIL12) booster. Specifically, A2B543 is comprised of autologous Tmod cells transduced with 2 lentiviral vectors: one expressing both the HLA-A*02-targeted blocker and the mesothelin-targeted CAR activator; and a second expressing the memIL12 booster. Interleukin 12 (IL-12) is a potent, pro-inflammatory cytokine that plays a crucial role in inducing antitumor immune responses; however, systemic IL-12 can be prohibitively toxic (Jia et al, *Front Immunol*, 2022). In A2B543, expression of the memIL12 cassette is under the control of an NFAT promoter and is induced during antigen engagement or T cell activation. This inducible memIL12 is designed to reduce the toxicity associated with systemic IL-12 while enhancing the long-term potency and persistence of Tmod (Zhang et al, *J Immunother Cancer*, 2025). **Methods:** EVEREST-2 (NCT06051695) is a phase 1/2, open-label, nonrandomized study evaluating the safety and efficacy of A2B543 in adults with recurrent/metastatic mesothelin-expressing cancers with tumor-associated HLA-A*02 LOH, including mesothelioma, colorectal, non-small cell lung, pancreatic, or ovarian cancer. Patients are enrolled through BASECAMP-1 (NCT04981119), a master pre-screening study that identifies patients with HLA LOH via next-generation sequencing and cryopreserves leukapheresis product. Upon progression, A2B543 is manufactured and then administered after lymphodepletion. The phase 1 primary objective is to evaluate the safety and tolerability of A2B543 and identify a recommended phase 2 dose (RP2D). The phase 2 primary objective is to assess overall response rate. Clinical trial information: NCT06051695. Research Sponsor: A2 Biotherapeutics, Inc.

TPS2674 **Poster Session**

A phase I, open-label, dose-escalation study of CAR001 (mRNA-engineered Nb-CAR.BiTE-γδ T cells) in patients with relapsed or refractory solid tumors. First Author: Der-Yang Cho, China Medical University Hospital, Taichung City, Taiwan

Background: Solid tumors are characterized by a highly immunosuppressive tumor microenvironment (TME). Key immune checkpoint molecules, such as HLA-G and PD-L1, are frequently expressed and act as barriers that limit the infiltration and efficacy of conventional CAR-T cell therapies. CAR001 is an investigational, allogeneic, mRNA-engineered Nb-CAR.BiTE-γδ T cell therapy. By utilizing the innate homing capabilities of γδ T cells and a dual-targeting mechanism, direct binding of HLA-G by T cells and secreting PD-L1 bispecific T-cell engagers from T cells, CAR001 is designed to overcome TME-mediated resistance. This study evaluates the safety and potential activity of repeat intravenous dosing of CAR001 in patients with advanced solid tumors. **Methods:** Study Design: This is an ongoing, multicenter, open-label, phase I dose-escalation study utilizing a standard 3+3 design or similar escalation schema. Patient Population: Adults with histologically confirmed refractory or relapsed solid tumors (including, but not limited to, colorectal cancer, glioblastoma, and triple-negative breast cancer) who have exhausted standard of care. Intervention: Patients receive escalating doses of CAR001 via intravenous infusion. The protocol allows for repeat dosing to enhance therapeutic persistence. Objectives: The primary objective is to evaluate the safety and tolerability of CAR001 and to determine the maximum tolerated dose (MTD) or recommended phase 2 dose (RP2D). Secondary objectives include assessing preliminary antitumor activity per iRECIST or RANO criteria, as well as characterizing the pharmacokinetic profile of the Nb-CAR.BiTE-γδ T cells. Safety Monitoring: Adverse events (AEs) are monitored using CTCAE v5.0, with specific focus on dose-limiting toxicities (DLTs), cytokine release syndrome (CRS), and immune effector cell-associated neurotoxicity syndrome (ICANS). Trial Status: This trial is currently active and enrolling patients. As of the submission deadline, dose-escalation cohorts are ongoing. To maintain the integrity of the study and comply with ASCO Trials in Progress guidelines, no formal analysis of clinical endpoints or treatment outcomes is provided. Clinical trial information: NCT06150885. Research Sponsor: None.

TPS2675 **Poster Session**

A phase 1/2 dose-escalation/expansion study of REGN10597 (anti–PD-1–IL2Rα-IL2) in patients with advanced solid tumors. First Author: Kyriakos Papadopoulos, START Center for Cancer Research, San Antonio, TX

Background: Interleukin 2 (IL-2) is a cytokine involved in lymphocyte expansion and differentiation during the anticancer immune response. Aldesleukin, an approved recombinant high-dose IL-2 therapy, has shown complete and durable responses in some cases; however, high-dose IL-2 is associated with severe toxicity, including vascular leak syndrome and pulmonary edema. Despite clinical advances with checkpoint inhibitor therapies, many advanced solid tumors continue to respond poorly to these treatments. REGN10597 is an antibody–cytokine fusion protein comprising a human anti–programmed cell death-1 antibody fused with a receptor-masked cytokine, IL2Rα-IL2. REGN10597 has demonstrated tumor inhibition, enhanced specificity, and reduced toxicity versus recombinant high-dose IL-2 in preclinical mouse models (Wu et al. Cell Rep Med 2024;5:101747). Here we describe BrILliance (NCT06413680), a study evaluating the safety, tolerability, pharmacokinetics, and preliminary antitumor activity of REGN10597 in patients with advanced solid tumors. **Methods:** This is an open-label, Phase 1/2, dose escalation/expansion, first-in-human, multicenter study evaluating REGN10597 in advanced or metastatic solid tumors. Patients must be aged ≥18 years with histologically or cytologically confirmed locally advanced or metastatic tumors and confirmed disease progression on standard-of-care therapy. During the dose escalation phase, patients will be enrolled to receive REGN10597 by intravenous infusion at the assigned dose level and schedule (additional dose schedules are available for further exploration). When the recommended Phase 2 dose level and schedule are determined, additional patients will be enrolled across two dose expansion cohorts: patients with locally advanced or metastatic melanoma (Cohort 1) and those with advanced or metastatic clear cell renal cell carcinoma (Cohort 2). Dose escalation primary endpoints include incidence of dose-limiting toxicities, incidence of treatment-emergent adverse events (including those leading to treatment discontinuation or death), incidence of serious adverse events, and the number of patients with Grade ≥3 laboratory abnormalities. The dose expansion primary endpoint is objective response rate per Response Evaluation Criteria in Solid Tumors version 1.1 (RECIST 1.1) by investigator assessment. Secondary endpoints for both phases include additional efficacy measures (best overall response, duration of response, disease control rate, time to response, and progression-free survival, all per RECIST 1.1), and pharmacokinetics and immunogenicity of REGN10597. Trial enrollment for the dose escalation phase began on October 1, 2024; as of January 27, 2026, 22 patients have been enrolled. Clinical trial information: NCT06413680. Research Sponsor: Regeneron Pharmaceuticals, Inc.

TPS2676 **Poster Session**

Biomarker study of BND-22 in combination with cemiplimab in solid tumors. First Author: Mohamed H. Derbala, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Immune checkpoint inhibitors benefit only a subset of patients, indicating a need to identify other therapeutic targets and understand the role of tumor microenvironment in shaping immune response. Immunoglobulin-like transcript-2 (ILT2) is an inhibitory receptor expressed on monocytes, dendritic cells, NK cells, and subset of T cells. ILT2 binds multiple MHC class-I molecules, with highest affinity for HLA-G, which is frequently overexpressed in solid tumors. Engagement of HLA-G/ILT2 pathway inhibits key immune functions, including cytotoxicity, cytokine production, antigen presentation, phagocytosis and proliferation. ILT2 expression can be upregulated following anti PD-1 therapy, suggesting a mechanism of resistance to checkpoint blockade. Inhibition of this pathway could potentially promote antitumor immune responses. BND-22, a first-in-class humanized IgG4 mAb, selectively binds to ILT2 on NK/T cells/macrophages, blocking its interaction with HLA-G. In preclinical studies and in a phase I trial, BND-22 alone and in combination with a PD-1 inhibitor demonstrated enhanced anti-tumor activity. The study revealed a dose-dependent activation in immune markers. Building on this finding, we initiated a phase II biomarker study (NCT06651593) of BND-22 in combination with cemiplimab, a recombinant human IgG4/kappa anti–PD-1 mAb, to further understand immune biology and explore the tumor microenvironment. **Methods:** The study has 2 patient cohorts: Cohort 1: patients with cholangiocarcinoma, who have had prior immunotherapy and Cohort 2: patients with microsatellite stable colorectal cancer and ovarian cancer who are anti–PD-1/PD-L1 naïve. Approximately 40 patients will be enrolled (10 per indication and an additional 10 to the best performing indication). The dose of BND-22 is 10 mg/kg IV on Day 1 every 3 weeks (Q3W), based on the dose escalation trial (NCT04717375). The dose of cemiplimab is the FDA-approved dose of 350 mg IV on Day 1 Q3W, starting at C2D1. Each cycle = 21 days. The combination will be administered for a max of 24 months in the absence of progression or until progression, unacceptable toxicity, death, withdrawal of consent, or discontinuation. Biopsy tissues and peripheral blood samples for biomarker analyses will be collected at baseline, on treatment, and at progression (for patients with CR, PR, or SD≥6 months). The primary objective is 1) to identify biomarkers related to mechanism of action and predictors of response, resistance, and survival 2) evaluate the association between the biomarkers and outcomes. The secondary objective is to evaluate efficacy, safety, and tolerability of this combination; identify imaging characteristics predictive of response and toxicity; and, evaluate TCR beta variable polymorphism and its relationship with immune-related adverse events. Enrollment is ongoing; 2 patients in Cohort 1 and 10 patients in Cohort 2 have been treated. Clinical trial information: NCT06651593. Research Sponsor: Sanofi; Regeneron.

TPS2677 **Poster Session**

The TIME trial: Phase II randomized controlled trial of time-of-day–specified nivolumab and ipilimumab for advanced melanoma. First Author: Michael Lowe, Emory University School of Medicine, Atlanta, GA

Background: Nivolumab/ipilimumab is standard of care for advanced melanoma patients based on Phase III randomized data from the CheckMate 067 trial. The recent 10-year outcomes results were reported with a melanoma specific survival for Nivolumab/ipilimumab of 52%. These data are very encouraging, but 50% of patients still succumb to their disease by 10-years. Preclinical data suggests that the circadian rhythm may influence the anatomic localization, function and activity of T cells, the target of immunotherapy. More T cells in the tumor or tumor-draining lymph node during initial immunotherapy administration may improve clinical responses and long-term outcomes. To investigate this idea, we performed a retrospective analysis, the MEMOIR study, finding that more evening infusions of immunotherapy were associated with significantly worse progression free and overall survival for metastatic melanoma patients. These findings have now been reproduced in other cancer histologies, in a larger meta-analysis, and in pre-clinical mechanistic studies. Considering these data, we hypothesize that evening infusions of immunotherapy will have worse progression free survival than either morning or midday infusions. **Methods:** The TIME trial is a three-arm phase II study of time-of-day specified administration of standard dose nivolumab/ipilimumab for metastatic melanoma. For newly diagnosed metastatic melanoma patients enrolled on study, they will be randomized to receive 4 cycles every 3 weeks of nivolumab/ipilimumab between 8:00-11:00 (Arm A), 11:00-14:00 (Arm B), or 14:00-17:00 (Arm C). Following these 4 cycles, they will receive standard of care maintenance nivolumab in a time-of-day agnostic fashion. Eligible patients must have stage IV unresectable cutaneous, acral or mucosal melanoma, no prior immunotherapy within 1 year, ECOG performance status of 0-1, age $\geq$ 18, no symptomatic or hemorrhagic brain metastases with none greater than 2 cm. The primary objective is to determine whether progression free survival for Arm A or Arm B is superior to Arm C. Secondary objectives include assessments of adverse events, melanoma specific survival and overall survival. We will evaluate the immune profiles of blood and tumor to assess the impact of time of drug administration on the circulating immune responses and the tumor immune microenvironment. 99 patients will be enrolled to detect a HR of 0.50 with at least 80% power and a Type 1 error rate of 0.1 (2-sided) for a comparison of A vs. C, and B vs. C. The study is open at Emory and has enrolled 3 patients; the study is undergoing regulatory review at MGH and Cedars-Sinai. Clinical trial information: NCT07155317. Research Sponsor: None.

TPS2678 **Poster Session**

A phase 1b, two-arm study of tolododekin alfa (ANK-101) in combination with an anti–PD-1/PD-L1 antibody in participants with advanced non–small cell lung cancer (NSCLC). First Author: Thomas Urban Marron, Division of Hematology and Medical Oncology, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Tolododekin alfa (ANK-101) is an anchored immunotherapy linking IL-12 to aluminum hydroxide through an alum-binding protein (ABP). Direct delivery to tumors results in prolonged IL-12 local retention and limited systemic absorption. A Phase 1 study in advanced solid tumors demonstrated ANK-101 was well tolerated with evidence of antitumor activity, recruitment of CD8+ T cells, and induction of local programmed cell death ligand 1 (PD-L1) expression. ANK-101 is now being evaluated in combination with PD-1/PD-L1 checkpoint blockade (ICB) in patients with non-small cell lung cancer (NSCLC). **Methods:** This study is a Phase 1b, two-arm, open-label study of direct injection (IT) of tolododekin alfa administered in combination with an anti-PD-1/PD-L1 antibody in participants with locally advanced or metastatic NSCLC. Cohort A will be conducted in participants who have progressed on prior standard of care treatment with ICB and platinum-based chemotherapy, either in combination or sequentially. Cohort B will enroll participants with untreated locally advanced or metastatic NSCLC with a PD-L1 tumor proportion score (TPS) $\geq$ 50%. Participants with targetable EGFR mutations or ALK rearrangements are excluded. In Cohort A, participants will receive tolododekin alfa at 250 μg/mL IT in combination with cetrelimab (anti-PD-1) intravenously (IV) Q3W at a dose of 360 mg for up to 8 cycles, followed by cetrelimab monotherapy for up to one year, unless they have unacceptable toxicity, clinical deterioration, confirmed tumor progression, or have withdrawn consent. In Cohort B, participants will receive tolododekin alfa at 250 μg/mL IT in combination with investigator's choice of an FDA-approved ICB for first-line use as monotherapy in patients with TPS $\geq$" role="presentation" tabindex="0">$\geq$ 50% IV Q3W at the approved dose for up to 8 cycles, followed by continued ICB according to the FDA-approved label. The primary objective is objective response rate by RECIST 1.1. Secondary endpoints include safety, duration of response, disease control rate, progression-free survival, and overall survival. In addition, lesion-level responses, serum PK analyses, and anti-drug antibody (ADA) levels will be assessed. Exploratory endpoints include measurements of selected serum cytokine levels and characterization of the composition of the tumor microenvironment before and on-treatment. This clinical trial is in progress. Clinical trial information: NCT07027514. Research Sponsor: Ankyra Therapeutics.

TPS2679 **Poster Session**

OP-NEU-101: A phase 1/2 open-label, dose finding and expansion study to investigate the safety and effectiveness and determine the optimal dose of N17350 administered intratumorally in participants with advanced solid tumors. First Author: Matteo S. Carlino, Westmead and Blacktown Hospitals, Melanoma Institute Australia and The University of Sydney, Sydney, NSW, Australia

Background: Despite advances in targeted therapies and immunotherapy, many patients with advanced solid tumors have limited treatment options. N17350 is a first-in-class, optimized therapeutic elastase designed for intratumoral administration that selectively induces cancer cell death by activating the neutrophil elastase (ELANE) pathway while preserving immune cell viability. Preclinical studies demonstrated broad antitumor activity across 30 cancer cell lines, 15 in vivo models, and 45 patient-derived tumor samples, as well as induction of antitumor immunity in both immunologically cold and hot tumors (Gujar et al., 2025; doi:10.1016/j.xcrm.2025.102446. Together with preclinical toxicology studies supporting a starting dose within the therapeutic range, these findings support the clinical evaluation of N17350. **Methods:** This first-in-human, multicenter, open-label Phase 1/2 study (OP-NEU-101) is evaluating the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of intratumorally administered N17350 in adults with advanced solid tumors. The study consists of a dose-finding and dose-optimization phase (Parts A1 and A2) followed by monotherapy expansion cohorts (Part A3). Dose-finding in participants with superficial (Part A1) and visceral lesions (Part A2) is guided by a Backfill Bayesian Optimal Interval (BF-BOIN) design to determine the maximum tolerated dose, optimal biologic dose, and/or recommended Phase 2 dose (RP2D). Once optimal dose(s) are identified, up to five tumor-specific expansion cohorts (data dependent: SCCHN, NSCLC, TNBC, cuSCC, Melanoma) may be opened to further characterize safety and clinical activity. Key Eligibility Criteria: Eligible participants are adults with advanced or metastatic solid tumors who have progressed on or are intolerant to standard therapies, have ECOG performance status 0–1, adequate organ function, and at least one superficial or visceral lesion suitable for intratumoral injection. Endpoints: The primary endpoints of the dose-finding phase are safety and tolerability, including the incidence of dose-limiting toxicities and treatment-emergent adverse events. Secondary endpoints include PK, immunogenicity, and preliminary antitumor activity assessed per RECIST v1.1 and/or itRECIST. Exploratory endpoints include evaluation of ELANE pathway activation, immune modulation, circulating tumor DNA, and multiomic analyses of tumor tissue and peripheral blood. The study has been initiated and will be enrolling participants at sites in the United States and Australia. Clinical trial information: NCT07339176. Research Sponsor: None.

TPS2680 **Poster Session**

A phase 1, first-in-human study of DS5361, a small-molecule, nonsense-mediated mRNA decay (NMD) inhibitor in patients with advanced/metastatic solid tumors (parts 1 and 2). First Author: Shiraj Sen, NEXT Oncology Dallas, Dallas, TX

Background: Despite the profound impact of immune checkpoint inhibitors (ICIs) on the treatment of patients with advanced or metastatic solid tumors, only a small proportion of patients experience meaningful responses, underscoring the need for novel therapies to maximize clinical benefit. High tumor mutational burden (TMB-H) and high microsatellite instability (MSI-H) are associated with improved efficacy of ICIs due to an increase in neoantigens, tumor-specific peptides displayed on tumor cell surfaces that are critical for antitumor immune responses. mRNAs harboring premature termination codons, including neoantigenic transcripts derived from frameshift mutations, are recognized and degraded by NMD. DS5361 is a potentially first-in-class, orally available, small-molecule inhibitor targeting the serine/threonine kinase SMG1, a key component of the NMD mechanism. DS5361 is designed to activate antitumor immunity by increasing neoantigen expression and, when administered in combination, to enhance ICI efficacy. **Methods:** DS5361-061 (NCT07182591) is a Phase 1, first-in-human, open-label, multicenter study (N≈66 for Parts 1 and 2) of DS5361 as monotherapy (Part 1) and in combination with pembrolizumab (Part 2). Patients must be adults, have measurable disease per Response Evaluation Criteria in Solid Tumours, version 1.1 (RECIST 1.1), and have an Eastern Cooperative Oncology Group performance status of 0 or 1. Patients with advanced or metastatic TMB-H and/or MSI-H solid tumors who are unable to tolerate standard treatment or have disease that is refractory to standard treatment, or for which no such treatment is available, will be enrolled across both parts. The primary objectives in Parts 1 and 2 (dose escalation) are to evaluate the safety and tolerability, and determine the maximum tolerated dose, of DS5361 as monotherapy in Part 1 and in combination with pembrolizumab in Part 2, and/or determine the recommended dose(s) for expansion in combination with pembrolizumab (Part 2 only). Safety endpoints include dose-limiting toxicities and treatment-emergent adverse events. Secondary endpoints include objective response, disease control, and duration of response, all assessed by the investigator per RECIST 1.1, as well as pharmacokinetics. Enrollment is ongoing. Clinical trial information: NCT07182591. Research Sponsor: Daiichi Sankyo.

TPS2681 **Poster Session**

Updated design of INVOKE: A phase 1 study of OKN4395, a first-in-class EP2/EP4/DP1 triple prostanoid receptor antagonist, in patients with advanced solid tumors. First Author: Stephane Champiat, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The immunosuppressive pathway of prostaglandin E_2 (PGE_2), part of the cyclooxygenase (COX) pathway, is upregulated in certain cancers and has been implicated in tumor evasion of CD8 T, NK, and dendritic immune cells, allowing tumor growth and metastasis (Jin et al., 2023). COX2 inhibitors, aspirin and nonsteroidal anti-inflammatories (NSAIDS) have shown some survival benefit in patients with gastrointestinal cancer and others (Cao et al., 2016; Martling et al., 2025; Takiuchi et al., 2018; Zhang et al., 2025); however, results are inconsistent, likely due to toxicity limiting complete blockade of the pathway, highlighting the need for more potent but selective inhibitors. OKN4395 is a first-in-class, highly selective, equipotent inhibitor of EP2, EP4, and DP1, downstream receptors for COX-derived PGE_2, and PGD_2, respectively. DP1 has described roles in immunosuppression and inhibition of apoptosis, supporting the therapeutic rationale (Luo et al., 2024; Peinhaupt et al., 2017). OKN4395 is hypothesized to modulate the tumor microenvironment to allow an effective immune response as monotherapy, and to potentiate the effect of immunotherapies such as checkpoint inhibitors, both of which are evaluated in INVOKE. Tumor types for INVOKE were selected using previously presented multimodal artificial intelligence (AI) drug-matching algorithms (Grimaldi, et al., 2025). **Methods:** INVOKE (OKN-4395-121; NCT06789172) is a Ph1a/1b, first-in-human study of OKN4395 (oral, BID) as monotherapy (mono) or in combination with a PD1 checkpoint inhibitor (combo), in patients with advanced solid tumors. Ph1a is a Bayesian dose escalation in mono with a new parallel substudy, followed by combo dose confirmation, primarily assessing safety, establishing the Ph1b dose. Response will be assessed in updated Ph1b (cohorts of n=20): select sarcomas (mono), non-small cell lung (combo), colorectal (combo), and gastric cancer (combo). Key inclusion criteria include COX-active (Ph1a) or above-listed (Ph1b) tumors, performance status 0-1, biopsy-amenable lesions, and adequate organ function. Active CNS metastases, upper GI bleed risk factors, untreated H. pylori infection, and concomitant NSAIDs/COX inhibitors/prostaglandins are exclusionary. A new and innovative 3-period, crossover substudy in parallel with Ph1a will explore the intra-participant effects of food and gastric pH on OKN4395 pharmacokinetics. Trial data, paired pre- and on-treatment biopsies, and exploratory biomarkers will be used to enhance development using advanced agentic AI systems, including a synthetic digital twin control arm, novel methodology of which is submitted to this meeting as well. Ph1a of the study is currently recruiting in the US, UK, and Australia. Dose Level 5 concluded in December 2025 with no DLTs to that date. Clinical trial information: NCT06789172. Research Sponsor: None.

TPS2682 **Poster Session**

Eiu-104101: A first-in-human phase 1a/1b study of EVOLVE104, a trispecific CD3×CD2×ULBP2/5/6 T-cell engager, in advanced urothelial and squamous cell carcinomas. First Author: Tony Fiorino, EvolveImmune Therapeutics, Branford, CT

Background: EVOLVE T cell engagers (TCEs) bind to a tumor antigen and to both CD3 and CD2 on T cells, thereby providing integrated costimulation via CD2 binding. EVOLVE TCEs demonstrate superior T cell activation and tumor cell killing compared to first generation TCEs, without excess cytokine release or tonic T cell activation, and may offer clinical benefits such as enhanced potency and duration of activity. UL16 binding proteins 2, 5 and 6 (ULBP2/5/6) belong to a family of cell surface proteins that are ligands for the NKG2D receptor. We have previously reported that cell-surface ULBP2/5/6 is not present in vital organs and found in some mucosal epithelia. Cell surface ULBP2/5/6 is found in urothelial carcinomas and squamous cell carcinomas (SCCs). With high expression on malignant cells and limited normal tissue expression, ULBP2/5/6 are intriguing targets for cancer immunotherapy. EVOLVE104 is a trispecific TCE that binds ULBP2/5/6 and both CD3 and CD2 on T cells. Preclinical studies with EVOLVE104 demonstrated enhanced T cell activation and killing of ULBP2/5/6-positive tumor cells compared to bispecific TCEs, and no safety concerns were identified in preclinical toxicity studies. With this encouraging preclinical profile, EVOLVE104 represents a novel approach to redirected T cell therapy in solid tumors. **Methods:** EIU-104101 is a first-in-human phase 1a/1b study evaluating EVOLVE104 monotherapy in adults with advanced solid tumors. Eligible tumor types include urothelial carcinoma of the bladder and SCCs of the bladder, lung, esophagus, tongue, skin, and anogenital region (penis, anus, vagina, vulva, cervix, and urethra). Subjects must have locally advanced or metastatic disease that has relapsed from, or is refractory to, standard-of-care therapies. Study objectives include assessing the safety, efficacy, pharmacokinetics and pharmacodynamics of EVOLVE104 and identifying the recommended phase 2 dose (RP2D). The phase 1a portion of the study will enroll up to 80 subjects using a Bayesian optimal interval (BOIN) dose-escalation scheme including backfill at dose levels deemed safe, with a key objective to identify one or more recommended doses for expansion (RDEs). Phase 1b includes two expansion cohorts: Cohort A, which will be a dose optimization cohort in a single indication (to be determined based on the phase 1a observations) in which 40 subjects will be randomized 1:1 to two RDEs to determine the RP2D; and Cohort B, which will enroll up to 40 subjects in other relevant indications. The study opened in October 2025 and is actively enrolling at US sites. ClinicalTrials.gov Identifier: NCT07217171. Clinical trial information: NCT07217171. Research Sponsor: EvolveImmune Therapeutics.

TPS2683 **Poster Session**

POLARIS: Polymetastatic lesion ablative radiotherapy with immunotherapy study. First Author: Evan Garrad, University of Illinois Chicago, Chicago, IL

Background: Patients with polymetastatic disease, most commonly defined as >5 metastatic lesions, often have limited treatment options and poor overall prognosis[1,2]. The emergence of immunotherapy (IO) has slowed disease progression in some patients; however, its efficacy is limited by tumor heterogeneity and patient-specific factors, including baseline health status[3]. Emerging data suggest a synergistic effect when combining IO with radiotherapy (RT), a strategy that has led to FDA-approved treatment approaches in non-small cell lung cancer (NSCLC)[4-6]. As multimodal cancer therapies evolve, robust methods to assess treatment response are increasingly important. Circulating tumor DNA (ctDNA) is a minimally invasive biomarker that has been shown to correlate with clinical response to therapy[7,8]. However, the kinetics and clinical significance of ctDNA in patients receiving combined IO and ablative RT remain poorly characterized. **Methods:** POLARIS is a pilot phase II, double-arm clinical trial evaluating the addition of ablative radiotherapy in patients with polymetastatic disease receiving immunotherapy. Twenty-eight patients with polymetastatic disease, defined as having at least 3 and no more than 10 metastatic lesions, and receiving immunotherapy alone for at least 30 days prior to registration will be enrolled at the University of Illinois Hospital & Health Sciences System (UIH). Patients will be stratified into two cohorts based on their response to immunotherapy after $\geq$3 months: Cohort A includes patients with investigator-assessed stable disease or partial response, while Cohort B includes patients with oligoprogression, defined as 1–5 sites of progressive disease within 3 months of registration. Both cohorts will receive ablative RT targeting up to 10 metastatic lesions in combination with ongoing immunotherapy. The primary endpoint is the proportion of patients achieving a molecular response, defined as a $>$50% reduction in ctDNA levels, at 8 weeks following ablative RT. Secondary endpoints include overall survival and progression-free survival at 6 and 12 months, objective response rate, and treatment-related adverse events (TRAEs). This trial is the first to prospectively evaluate ablative radiotherapy as an adjunct to immunotherapy while integrating ctDNA as a biomarker of treatment response in polymetastatic disease. Clinical trial information: NCT07269080. Research Sponsor: University of Illinois Chicago.

TPS2684 **Poster Session**

Pharmacokinetics and pharmacodynamics evaluation in phase I trial of APX-343A, selective NOX inhibitor targeting CAF-mediated immunosuppression in patients with advanced solid tumors. First Author: Sung Hwan Moon, Aptabio Therapeutics, Yongin-Si, South Korea

Background: Cancer-associated fibroblasts (CAFs) drive fibrotic remodeling and immune exclusion in solid tumors and contribute to resistance to immune checkpoint inhibitors (ICIs). CAF-mediated immune suppression is regulated by upstream oxidative signaling pathways. NADPH oxidases (NOXs) are upregulated in CAFs and promote fibrotic remodeling and myeloid cell–mediated inhibition of cytotoxic T-cell function, linking CAF activity to immune exclusion and immunotherapy resistance. APX-343A is a selective NOX1/2/4 inhibitor designed to modulate CAF-associated tumor biology. This ongoing Phase 1 study evaluates pharmacokinetic (PK) and pharmacodynamic (PD) components to assess translational biomarkers of NOX target engagement and CAF-driven immune modulation supporting dose selection and rational combination strategies with immunotherapy. **Methods:** This is a Phase 1, dose-escalation study (NCT07123415) evaluating the safety, tolerability, PK, PD, and preliminary antitumor activity of orally administered APX-343A as monotherapy (Part A; 100–600 mg BID) and in combination with pembrolizumab (Part B; 200–600 mg BID) in patients with advanced solid tumors. Dose escalation is conducted independently using dose-limiting toxicity–based escalation in Part A and a Bayesian Optimal Interval (BOIN) design in Part B to determine the maximum tolerated dose (MTD) and recommended Phase 2 dose (RP2D). PK assessments are conducted in Part A to evaluate dose proportionality and support RP2D determination, including Cmax, Tmax, area under the concentration–time curve (AUC), and accumulation. PD assessments use peripheral blood and tumor tissue samples to evaluate biomarkers of NOX pathway inhibition and CAF-driven immune modulation, including NOX isoforms (NOX1/2/4), CAF-associated markers, and immune-related cytokines and chemokines (e.g., interleukins, CCL2). Integrated PK/PD analyses explore exposure–biomarker relationships. This ongoing Phase 1 trial of APX-343A is actively enrolling, with Part A dose-escalation cohorts underway. Integrated PK and PD assessments are designed to establish translational evidence of NOX target engagement and CAF modulation, providing a mechanistic foundation for dose selection and rational combination strategies with ICI. Clinical trial information: NCT07123415. Research Sponsor: None.

TPS2685 **Poster Session**

A phase 1 study of PHST001, an anti-CD24 monoclonal antibody, in adult patients with advanced relapsed and/or refractory solid tumors. First Author: Ulka N. Vaishampayan, Division of Hematology/Oncology, University of Michigan, Ann Arbor, MI

Background: Macrophages are the most abundant immune cells in tumors and can directly phagocytose tumor cells and promote broad anti-tumor immunity. However, phagocytosis can be inhibited by macrophage checkpoints, also known as 'don't eat me' signals. One such checkpoint is the immunomodulatory protein CD24 that is overexpressed in many tumors and associated with poor clinical prognosis. CD24 inhibits macrophage phagocytosis of tumor cells via binding to Siglec-10 on macrophages. PHST001 is a high affinity anti-CD24 IgG4 antibody that blocks multiple glycoforms of CD24 and induces macrophage phagocytosis of tumor cells in a wide range of preclinical models. In addition, PHST001 improves tumor control and survival in murine models when combined with multiple chemotherapies as chemotherapy-induced tumor cell stress may improve macrophage phagocytosis of tumor cells when combined with CD24 blockade. Thus, CD24 blockade has potential as monotherapy and in combination with other cancer therapies to enhance tumor cell phagocytosis and improve patient survival. **Methods:** PHST001-101 is an open-label, first-in-human, Phase 1 study in patients $\geq$ 18 years of age with advanced relapsed and/or refractory solid tumors (NCT06840886). In Phase 1a, patients receive escalating doses of PHST001 administered Q3W as an IV infusion at one of nine dose levels. Phase 1b combines PHST001 with chemotherapy in patients with ovarian cancer, endometrial cancer, or cholangiocarcinoma in safety run-in groups and tumor-specific expansion cohorts. Key inclusion criteria include age $\geq$ 18 years, evidence of measurable disease, an ECOG performance status of 0 or 1, and adequate organ function. Key exclusion criteria include a diagnosis of immunodeficiency, active CNS disease, or active autoimmune disease. The primary objective is to assess the safety and tolerability of PHST001 as monotherapy and in combination with chemotherapy, and to assess the preliminary antitumor activity of PHST001 in combination with chemotherapy. Secondary objectives include assessing antitumor activity of monotherapy and pharmacokinetics (PK) of PHST001. Exploratory objectives include evaluating the relationship between PK and pharmacodynamics (receptor occupancy, cytokine profiling, changes in ctDNA, and immune cell subsets in the tumor), immunogenicity of PHST001, antitumor activity in patients treated beyond progression, and patient-reported outcomes. The study enrolled the first patient treated in April 2025 and is currently enrolling patients in Phase 1a at Dose Level 8 (18 mg/kg) with no DLTs to date. Enrollment in Phase 1b is anticipated to begin in early 2026. Clinical trial information: NCT06840886. Research Sponsor: Pheast Therapeutics.

TPS2686 **Poster Session**

A phase 1/2a, multicenter, first-in-human, open-label clinical trial evaluating MDX2004 monotherapy in patients with advanced tumors. First Author: Jordan Ellis Cohen, Calvary Mater Newcastle, Newcastle, NSW, Australia

Background: MDX2004 is a trispecific antibody–fusion protein developed as an immunotherapy for advanced cancers. It is designed to stimulate T cells through engagement of CD3, CD28, and 4-1BB, thereby enhancing immune activation. MDX2004 is expected to promote activation and expansion of T lymphocytes, including stem and memory T-cell populations. **Methods:** This Phase 1/2, multicenter, first-in-human, open-label clinical trial evaluates MDX2004 in patients with advanced or metastatic solid tumors (NCT07110584). The study includes a Phase 1a dose-escalation stage guided by a Bayesian Optimal Interval (BOIN) design targeting a maximum tolerated dose toxicity rate of 30%; a Phase 1b indication-optimization stage in up to five tumor types; a Phase 1c dose-optimization stage in up to three indications; and a Phase 1d/2a expansion at the recommended Phase 2 dose (RP2D) in a single indication. In Phase 1a, patients with advanced solid tumors receive escalating intravenous doses of MDX2004. Phase 1b evaluates a selected dose in patients with homogeneous indications to assess preliminary efficacy. In Phase 1c, patients with selected indications are randomized 1:1 to two dose cohorts using a Bayesian Optimal Phase 2 (BOP2) design. Once the RP2D is established, Phase 1d/2a will enroll approximately 30 patients into a single cohort using a BOP2 design. The primary objectives across study phases are to characterize the safety, tolerability, and antitumor activity of MDX2004. Secondary endpoints include time to response, disease control rate, duration of response, pharmacokinetics, and immunogenicity. Radiologic tumor assessments are performed every 8 weeks, and treatment continues until disease progression per RECIST v1.1 (investigator assessed), unacceptable toxicity, withdrawal of consent, or another protocol-defined discontinuation criterion. The study is planned to be conducted in Australia, Israel, Moldova; patient recruitment is ongoing. Clinical trial information: NCT07110584. Research Sponsor: None.

TPS2687 **Poster Session**

Phase 1 clinical trial investigating the safety, pharmacokinetics, pharmacodynamics, and antitumor activity of AB821 in adult patients with locally advanced or metastatic melanoma and other solid tumor malignancies (NCT 07027488). First Author: Harriet M. Kluger, Yale University School of Medicine, Smilow Cancer Center, New Haven Hospital, New Haven, CT

Background: In recent years, T-cell enhancement strategies have achieved notable survival benefits in patients with cancer. While cytokine therapy with both IL-2 and IL-21 demonstrate anti-cancer activity through enhanced proliferation, survival and function of antigen specific CD8+ T cells, their use is limited by off-target effects and rapid clearance. AB821 is a fusion of a CD8-targeting antibody that binds to the CD8$\alpha\beta$ heterodimer on CD8+ T cells and an IL-21 mutein containing a mutation that attenuates affinity for the IL-21receptor. In pre-clinical experiments, AB821 promotes CD8+ T-effector cell cytotoxicity and CD8+ T-cell memory and demonstrates both robust tumor growth inhibition and minimal toxicity in immune checkpoint inhibitor refractory tumor models. Notably, AB821 avoids activation of other IL-21R-expressing cell types, including CD4+ T cells, NK cells, B cells, dendritic cells, intermediate monocytes, and nonclassical monocytes, that can act as pharmacologic sinks or contribute to off-target toxicity. **Methods:** This first-in-human phase 1 dose-escalation clinical trial is designed to assess the safety, pharmacokinetics, pharmacodynamics, immunogenicity and preliminary anti-tumor activity of AB821 monotherapy administered every 2 weeks (Q2W) in patients (pts.) with recurrent locally advanced or metastatic melanoma and other immune-responsive solid tumor malignancies. Pts. with melanoma are required to have previously been treated with an inhibitor of PD1/L1 while pts. with other cancer types are required to have received a previous systemic treatment regimen. The primary objective of the study is to assess the safety and tolerability of AB821 and identify a candidate recommended phase 2 dose for further evaluation. AB821 is being administered as a 30-minute IV infusion on day 1 of each 2-week treatment cycle with therapy continued for a maximum duration of two years (52 cycles) or as long as participants experience clinical benefit as determined by the treating investigator. Dose-escalation and/or de-escalation decisions is being guided by a BF-BOIN design (Liu 2015; Yuan 2016) employing a target toxicity probability of 0.30 with up to 20 total pts. enrolled in backfill cohorts at the RP2D or lower dose levels determined by the investigators to be potentially efficacious in order to better assess the drug's safety and efficacy. Accrual is ongoing. Specific dose levels and inclusion/exclusion criteria will be presented. Clinical trial information: NCT07027488. Research Sponsor: Asherbio Therapeutics.

TPS2688 **Poster Session**

A phase I/IIa study to evaluate the safety and tolerability, activity, and PK of a potential novel CNTN4-targeted checkpoint inhibitor, EP0089, in patients with advanced solid tumors. First Author: Hendrik-Tobias Arkenau, Ellipses Pharma, London, United Kingdom

Background: Contactin 4 (CNTN4) has recently been identified as a novel cancer target which is overexpressed across a range of tumor types, including gastrointestinal, genitourinary, melanoma, breast and lung. Preclinical data shows that CNTN4 functions as an immune checkpoint through its binding to the T-cell transmembrane protein APP (Amyloid Precursor Protein). The interaction between CNTN4 on the surface of tumor cells and APP diminishes T cell receptor signaling cascades, inhibiting the activation and proliferation of CD4+ and CD8+ T cells. Tumor upregulation of CNTN4 may facilitate tumor immune evasion. Elevated CNTN4 levels have been associated with poorer outcomes for patients treated with anti-PD-1 checkpoint inhibitors. Therapeutic agents that block the interaction of CNTN4 with APP therefore have the potential to address significant unmet medical needs across a range of tumor types. EP0089 is a humanized IgG4 monoclonal antibody which specifically binds CNTN4 and inhibits the interaction between CNTN4 and APP, thereby enabling an immune response within the tumor microenvironment. *In vitro* and *in vivo* studies demonstrated that EP0089 neutralized CNTN4-mediated suppression of T cell activation and promoted killing of CNTN4 over-expressing tumors. **Methods:** This is a first-in-human, open-label, phase I/IIa study (NCT07030478). Eligible patients will have a confirmed diagnosis of an advanced solid tumor with no available standard therapy or for whom standard therapy has failed, ECOG performance status of 0-1, life expectancy greater than 3 months, and measurable disease per RECIST v1.1 (or specified disease-specific guidelines). The population will be enriched for tumor types known to express CNTN4, including gastric, gastro-esophageal, esophageal adenocarcinoma, hepatocellular, bladder, gallbladder, endometrial, melanoma, and prostate. The primary objective is to determine the maximum tolerated dose and recommended phase II dose of EP0089. The secondary objectives are to characterize the PK and immunogenicity profile of EP0089 and assess preliminary antitumor activity. Exploratory objectives are to evaluate biomarkers of response, including the impact of CNTN4 expression and other PD biomarkers. Part A consists of dose-escalation, utilizing a 3+3 design, and dose expansion to further evaluate dose levels/regimens of interest. Part B will be determined based on review of Part A data and may include further dose optimization, and/or evaluation of specific populations of interest. Patients will initially receive EP0089 by IV infusion once every 2 weeks, subject to ongoing Safety Monitoring Committee review throughout dose escalation. The study is being conducted in the Republic of Korea, Australia and United States and later in Europe. Target recruitment is approximately 250 patients. Clinical trial information: NCT07030478. Research Sponsor: None.

TPS2689 **Poster Session**

TREGCHECK 102: A study of tagmokitug (CHS-114) in combination with toripalimab and/or other treatments in participants with advanced solid tumors. First Author: Dani Ran Castillo, City of Hope, Duarte, CA

Background: Advanced solid tumors frequently exhibit resistance to standard therapies, including immune checkpoint inhibition. Intratumoral Tregs have been associated with immune suppression, tumor progression and anticancer resistance. Intratumoral Tregs preferentially express CCR8 and are abundant in many solid tumors (Plitas 2020; Plitas 2016; Kidani 2022). Tagmokitug is a novel, selective cytolytic anti-CCR8 mAb designed to deplete CCR8+ Tregs and remodel the tumor microenvironment to promote antitumor immunity. Preclinical and phase 1 clinical studies show tagmokitug can significantly deplete CCR8+ intratumoral Tregs, increase immune activation and has antitumor activity in combination with a PD-1 inhibitor (Wang 2026; Worden 2025; Kapoor 2025). These findings warrant evaluation of tagmokitug in combination with toripalimab, a PD-1 inhibitor, and/or other anticancer therapies across multiple tumor types. **Methods:** This multicenter, open-label, phase 1b/2a study evaluates tagmokitug in combination with toripalimab and/or other therapies in adults with advanced solid tumors in 4 cohorts: gastric, gastroesophageal junction (GEJ), and esophageal adenocarcinoma; second-line esophageal squamous cell carcinoma (ESCC); first-line ESCC; and advanced MSS/pMMR colorectal cancer. Eligible participants have histologically or cytologically confirmed advanced or metastatic solid tumors not amenable to curative therapy, measurable disease per RECIST v1.1, ECOG 0–1, and adequate organ function. Key exclusions include active autoimmune disease requiring systemic therapy, uncontrolled cardiovascular conditions, or other factors interfering with study participation. Tagmokitug is administered IV Q3W at pharmacologically active doses following toripalimab 240 mg IV and/or other anticancer therapies where indicated per protocol. Imaging assessments are performed every 6 weeks through week 24, every 9 weeks through week 51 and every 12 weeks through week 99. Patients continue treatment until disease progression, unacceptable toxicity, or withdrawal of consent. The primary objective is to evaluate the safety and tolerability of tagmokitug in combination with toripalimab and/or other anti-cancer therapies as measured by adverse events and laboratory abnormalities. Secondary endpoints include ORR, DOR, DCR, and PFS per RECIST v1.1, and assessment of PK and ADA. Exploratory endpoints include OS and biomarker analyses including evaluation of CCR8+ Tregs in tumors. Enrollment is ongoing. Approximately 150 participants are planned across all cohorts. Additional cohorts may be added based on emerging data. Clinical trial information: NCT06657144. Research Sponsor: Coherus Oncology.

TPS2690 **Poster Session**

Cohort expansion of a phase I study of PLN-101095, a first-in-class dual $\alpha_v\beta_8/\alpha_v\beta_1$ integrin inhibitor, in combination with pembrolizumab in patients with advanced solid tumors refractory to immune checkpoint inhibitors (ICI). First Author: Timothy A. Yap, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Transforming growth factor-β (TGF-β) drives immunosuppression and T-cell exclusion in solid tumors and contributes to immune checkpoint inhibitor (ICI)-acquired resistance. The integrins $\alpha_v\beta_8$ and $\alpha_v\beta_1$ activate latent TGF-β in the tumor microenvironment, promoting immune escape. PLN-101095 is a first-in-class, oral dual $\alpha_v\beta_8/\alpha_v\beta_1$ inhibitor designed to block TGF-β activation and restore antitumor immunity in patients with advanced solid tumors refractory to prior ICI. Part 1 of our study (NCT06270706) employed a Bayesian optimal interval design for dose escalation. The Part 2 expansion cohorts were driven by Part 1 efficacy signals, including 4 responders with secondary resistance to ICI, most of whom had high tumor mutational burden (TMB-H) prior to baseline. **Methods:** This is an ongoing Phase 1 open-label multicenter study conducted in the United States. Part 1 (dose escalation) enrolled patients with advanced or metastatic solid tumors who had either primary or secondary resistance to prior ICI. Part 2 (dose expansion) will enroll only patients meeting Society for Immunotherapy of Cancer (SITC) criteria for secondary resistance to prior ICI therapy based on a Simon 2-stage design. The Part 2 expansion cohorts will be as follows: 1) non-small cell lung cancer; 2) head and neck squamous cell carcinoma; 3) clear cell renal cancer; and 4) TMB-H tumors (historical ≥10 mutations/megabase, as determined by local testing with a Clinical Laboratory Improvement Amendments–certified next-generation sequencing [NGS] assay). The target sample size for cohorts 1-3 is 19 patients each, and the target for cohort 4 is 36 patients. The primary endpoints are objective response rate (ORR) and disease control rate (DCR) per immune RECIST. The secondary endpoints are pharmacokinetics (PK), safety and tolerability, and duration of response (DOR). Planned exploratory biomarkers analyses include characterization of integrin expression, TGF-β and immune-related gene expression, and tumor microenvironment (TME) in tumor biopsies. Plasma cytokine profiling and circulating tumor DNA (ctDNA) will also be examined. Clinical trial information: NCT06270706. Research Sponsor: Pliant Therapeutics, Inc.

TPS2691 **Poster Session**

Phase II open-label trial of neoadjuvant immunotherapy in combination with CAPOX for resectable non-metastatic proficient mismatch repair (pMMR) colon cancer: NICER study. First Author: Atif Iqbal, Baylor College of Medicine, Houston, TX

Background: Colorectal cancer (CRC) is the third most common malignancy worldwide. Immune checkpoint inhibition has transformed outcomes in deficient mismatch repair (dMMR/MSI-H) CRC but has demonstrated limited efficacy in metastatic proficient mismatch repair (pMMR) tumors, likely related to low tumor mutational burden and limited immune infiltration. Emerging neoadjuvant studies suggest that earlier exposure to immunotherapy may enhance antitumor immunity and induce pathologic responses in pMMR colon cancer. Neoadjuvant chemotherapy may further augment immunogenicity through tumor debulking, antigen release, and modulation of the tumor immune microenvironment. Combination chemo-immunotherapy has improved outcomes across multiple solid tumors and may overcome resistance to immune checkpoint blockade. Early neoadjuvant immunotherapy studies in pMMR colon cancer have demonstrated encouraging pathologic responses without compromising surgical outcomes. The NICER study evaluates the safety, feasibility, and biological activity of neoadjuvant atezolizumab plus CAPOX in resectable pMMR colon cancer. Correlative studies include longitudinal circulating tumor DNA (ctDNA) analysis and paired tissue assessment to characterize immune microenvironmental changes following treatment. **Methods:** This is a phase II, open-label study evaluating neoadjuvant atezolizumab in combination with capecitabine and oxaliplatin (CAPOX) in patients with resectable, non-metastatic pMMR colon adenocarcinoma. The planned accrual is 28 patients. Participants receive four 3-week cycles of neoadjuvant atezolizumab plus CAPOX, followed by standard-of-care surgical resection. Adjuvant chemotherapy is permitted per investigator discretion for high-risk patients. Key eligibility criteria include pMMR colon adenocarcinoma with tumor ≥12 cm from the anal verge and at least one high-risk feature (elevated CEA, low lymphocyte-to-monocyte ratio, poor differentiation, lymphovascular or perineural invasion, CT-defined T3–T4 disease ≥4 cm, or regional lymphadenopathy). Exclusion criteria include metastatic disease, autoimmune disorders, recent malignancy, or synchronous colorectal primaries. The primary endpoint is tumor regression grade (TRG) using the modified Ryan scoring system. The regimen will be considered promising if the post-therapy TRG 1 rate is ≥15%, compared with an expected rate of 0% with upfront surgery. Secondary endpoints include pathologic complete response, R0 resection rate, lymph node yield, safety, surgical timing, recurrence outcomes, and quality of life. As of January 2026, 7 of 28 planned patients have been enrolled since accrual began in July 2025. ClinicalTrials.gov ID NCT05870800. Clinical trial information: NCT05870800. Research Sponsor: Genentech, Inc. (subsidiary Roche - Switzerland).

TPS2692 **Poster Session**

Induction adebrelimab combined with chemotherapy followed by response-adaptive concurrent chemoradiotherapy guided by PET-CT in locally advanced unresectable esophageal squamous cell carcinoma: A prospective, single-arm, phase II study. First Author: Jun Wang, Department of Radiation Oncology, The Fourth Hospital of Hebei Medical University, Shijiazhuang, Hebei, China

Background: Concurrent chemoradiotherapy (CCRT) is the standard treatment for locally advanced unresectable esophageal cancer. Currently, data on PD-L1 inhibitors combined with chemoradiotherapy in this setting still remain limited. Furthermore, the efficacy of induction immunotherapy prior to CCRT, and the utility of PET-CT assessment to guide subsequent CCRT regimens, have not been explored. This study aims to evaluate the efficacy and safety of induction adebrelimab (an anti-PD-L1 antibody) combined with chemotherapy, followed by a PET-CT guided adaptive chemotherapy regimen during CCRT for locally advanced unresectable esophageal squamous cell carcinoma (ESCC). **Methods:** This single-arm, open-label, exploratory study will recruit 36 patients with locally advanced unresectable ESCC (clinical stage T1N+M0 or T2-4bNxM0) who have not received prior antitumor treatment. Patients will undergo 2 cycles of induction therapy with adebrelimab (1200 mg, d1, iv, q3w) plus the TP regimen (nab-paclitaxel 180 mg/m² or paclitaxel 135 mg/m², d1, iv; carboplatin AUC=5, d1, iv, q3w). Following induction, response will be assessed via PET-CT. Responders (defined as SUV reduction ≥35% or partial response) will continue with the TP regimen (nab-paclitaxel 60 mg/m² or paclitaxel 50 mg/m², d1, iv; carboplatin AUC=2, d1, iv, qw for 5 cycles) during concurrent radiation (50.4–60 Gy/28–33f). Non-responders will switch to the FP regimen (fluorouracil 750–1000 mg/m², civ 96h; cisplatin 75 mg/m², d1, iv, q4w for 2 cycles) during concurrent radiation. All patients will proceed to maintenance therapy with adebrelimab following CCRT until disease progression or unacceptable toxicity. The primary endpoint is the 1-year progression-free survival (PFS) rate. Secondary endpoints include the clinical complete response (cCR) rate, objective response rate (ORR), disease control rate (DCR), duration of response (DoR), PFS, overall survival (OS), and safety profile. Clinical trial information: NCT07112833. Research Sponsor: None.

TPS2693 **Poster Session**

ASCEND: A phase 1/2, dose-escalation, optimization, and dose-expansion study to evaluate the safety and antitumor activity of CR-001 in adults with locally advanced or metastatic solid tumors. First Author: Meredith Pelster, Sarah Cannon Research Institute, Nashville, TN

Background: CR-001 is a tetravalent bispecific antibody targeting anti-programmed cell death-1 (PD-1) and vascular endothelial growth factor (VEGF), designed to enhance antitumor activity through combined immune modulation and antiangiogenic effects. Its proposed mechanism of action involves dual binding and blockade of both PD-1/programmed death ligand-1 (PD-L1) and VEGF/vascular endothelial growth factor receptor 2 (VEGFR2) signaling. The blockade of VEGF signaling is aimed at inhibiting tumor angiogenesis and reversing immunosuppressive effects in the tumor microenvironment, while PD-1 binding is aimed at preventing T-cell suppression, thereby promoting the immune recognition and elimination of tumor cells. The established benefit/risk profiles and regulatory precedents for PD-1-, VEGF-, and dual-pathway-directed antibodies support evaluation of CR-001 in solid tumors. **Methods:** ASCEND (NCT07335497) is a global, first-in-human, open-label, phase 1/2 study assessing CR-001 monotherapy in adults with advanced solid tumors. The purpose of this study is to determine the safety and tolerability of CR-001 and identify the maximum tolerated dose, and/or recommended phase 2 dose. The study will initially involve three parts: dose escalation, backfill, and dose optimization. Key eligibility criteria include: age ≥18 years; locally advanced (nonresectable) or metastatic hepatocellular carcinoma, biliary tract cancer, gastric or gastroesophageal junction cancer, colorectal cancer, endometrial cancer, cervical cancer, ovarian cancer, or non-small-cell lung cancer; and progression on, intolerance to, or ineligibility for local standard-of-care anticancer therapies. Additional criteria include ≥1 measurable lesion and ECOG performance status 0–1. As part of a standard 3+3 dose-escalation design, CR-001 is planned to be administered at 4 dose levels as an intravenous infusion every 2 or 3 weeks. Tumor-specific backfill cohorts will enroll concurrently with dose escalation. Earlier-line participants, including those untreated in the advanced or metastatic setting, may also be eligible to participate in backfill cohorts. The recommended phase 2 dose will be determined based on review of pharmacokinetics/pharmacodynamics, safety, tolerability, and preliminary signs of antitumor activity. Up to 290 patients are planned to be enrolled across the dose-escalation, tumor-specific backfill, and dose-optimization cohorts. This global trial is currently enrolling. Clinical trial information: NCT07335497. Research Sponsor: Crescent Biopharma.

TPS2694 **Poster Session**

Efficacy and safety of QL1706-based combination therapy in recurrent or metastatic endometrial carcinoma previously treated with chemotherapy and immune checkpoint inhibitors: A single-arm, prospective, phase II trial. First Author: Lu Sun, Tianjin Medical University Cancer Institute & Hospital, Tianjin, China

Background: Patients with advanced endometrial cancer who have progressed after platinum-based chemotherapy and immune checkpoint inhibitors have limited subsequent treatment options and a very poor prognosis. Iparomlimab and tuvonralimab injection (QL1706) is a bifunctional combination antibody targeting both programmed cell death protein 1 (PD-1) and cytotoxic T-lymphocyte antigen 4 (CTLA-4), developed using the MabPair biotechnology platform. This study aims to evaluate the efficacy and safety of QL1706 combined with chemotherapy ± bevacizumab in patients with recurrent or metastatic endometrial cancer previously treated with immune checkpoint inhibitors. **Methods:** In this prospective, single-arm, multicenter phase II clinical trial, up to 30 participants will be enrolled. Eligible patients must be aged ≥18 years, have an Eastern Cooperative Oncology Group Performance Status score of 0 to 1, be diagnosed with recurrent or metastatic endometrial carcinoma, have previously received PD-(L)1 therapy for over 6 months, and have experienced disease progression during or after prior chemotherapy and PD-(L)1 targeted therapy. Up to two prior lines of systemic therapy are permitted. Patients who previously received PD-(L)1 plus CTLA-4 targeted therapy or discontinued anti-PD-1/PD-L1 antibody therapy due to related toxicities are excluded. Enrolled patients will receive QL1706 (5 mg/kg every 3 weeks) combined with chemotherapy (investigator's choice, administered for 3–6 cycles) ± bevacizumab (15 mg/kg every 3 weeks) until disease progression, unacceptable toxicity, or other protocol-specified termination events. The primary endpoint is the objective response rate (ORR) as assessed by the investigator according to RECIST v1.1. Secondary endpoints include progression-free survival (PFS), overall survival (OS), duration of response (DoR), and safety. As of January 2026, 5 of the planned 30 patients have been enrolled. Clinical trial information: NCT06917092. Research Sponsor: None.

TPS2695 **Poster Session**

SYNERGY: A phase 1b/2 study of nenocorilant, a selective glucocorticoid receptor antagonist, plus nivolumab in patients with advanced solid malignancies. First Author: Omid Hamid, The Angeles Clinic and Research Institute, A Cedars-Sinai Affiliate, Los Angeles, CA

Background: Acting through the glucocorticoid receptor (GR), glucocorticoids (GCs) suppress the anticancer immune response by decreasing antigen presentation, exhausting CD8+ T-cell effector function, and increasing the immunosuppressive function of regulatory T cells and tumor-infiltrating myeloid cells. The use of GCs with anti-programmed death (ligand) 1 (anti-PD[L]1) therapy is associated with poor outcomes in several solid tumor types. Selective GR antagonists (SGRAs) inhibit the effects of GCs at the GR and show synergistic activity with cytotoxic chemotherapy, as demonstrated by the phase 3 ROSELLA study in patients with platinum-resistant ovarian cancer (Olawaiye *Lancet* 2025). SGRAs enhance tumor growth inhibition when combined with anti-PD1 therapy in syngeneic mouse tumor models that are refractory to immune checkpoint inhibition (Greenstein *Int Immunopharmacol* 2023). We hypothesize that GR antagonism with nenocorilant, an SGRA, may enhance or restore sensitivity to anti-PD(L)1 therapy and provide clinical benefit for patients with solid malignancies. **Methods:** This phase 1b/2, open-label, multicenter study (NCT07276373) is evaluating nenocorilant + nivolumab in patients with advanced solid malignancies. Key eligibility criteria for phase 1b include having received standard-of-care therapies, no prior immune-related adverse events (AEs) grade ≥3 or leading to anti-PD(L)1 discontinuation, no ongoing requirement for GCs, and evaluable disease (per Response Evaluation Criteria in Solid Tumors version 1.1). Treatment will continue until disease progression or discontinuation criteria are met. Nenocorilant will be given orally once daily in escalating doses (starting at 200 mg) across 3 cohorts of 10 patients each. Nivolumab 240 mg will be given intravenously once every 2 weeks. If ≤3 patients in a cohort experience dose-limiting toxicities (DLTs) during the 28-day evaluation period, enrollment will proceed to the next cohort at a higher dose of nenocorilant. Primary objectives include characterizing safety/tolerability (DLTs, AEs, serious AEs, dose modifications, and treatment discontinuations due to AEs) and determining the maximum tolerated dose and/or optimal dose/schedule. Secondary objectives are to characterize the anticancer activity, pharmacokinetics, and corrected QT interval effects of this combination. Safety endpoints will be summarized using descriptive statistics and time-to-event endpoints will be estimated using Kaplan-Meier methods. Data from the currently enrolling phase 1b part of the study will inform the dosing regimen for phase 2, which will further characterize the anticancer activity and safety of nenocorilant + nivolumab in specific solid malignancies. Clinical trial information: NCT07276373. Research Sponsor: Corcept Therapeutics.

TPS2696 **Poster Session**

Phase I study of zeaxanthin alone or in combination with pembrolizumab in metastatic solid tumors. First Author: Philip Adam Friedlander, Division of Hematology and Medical Oncology, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Zeaxanthin is a carotinoid synthesized by plants that accumulates via dietary intake in the macula. Preclinical studies demonstrated anti-proliferative properties in cancer cell lines *in vitro*. In uveal melanoma cell lines SP6.5 and C918, zeaxanthin reduced cell viability in a dose dependent manner while not doing so in normal ocular melanocytes. Decreased cell viability associated with decreased expression of anti-apoptotic proteins bcl-2 and bcl-xL and increased expression of pro-apoptotic bak and bax (1). Anti-proliferative effects were demonstrated in nude mice inoculated in the choroid with uveal melanoma cells (2). Zeaxanthin enhances anti-tumor immunity. Screening a blood nutrient compound library found zeaxanthin to augment CD8+ T-cell activity through direct engagement with the T-cell receptor (3). Murine models showed zeaxanthin enhanced anti-cancer efficacy of anti-PD-1 immunotherapy (3). Pro-apoptotic and immunomodulatory properties of zeaxanthin suggest potential for efficacy in treating cancer patients warranting clinical investigation. The primary objectives of this phase I study are to determine safety and tolerability of escalating doses of zeaxanthin monotherapy or combination of zeaxanthin plus pembrolizumab in patients with metastatic solid tumor malignancies and to determine MTD and recommended phase 2 dose. Secondary objectives assess pharmacokinetics and efficacy. Exploratory endpoints assess blood based biomarkers, transcriptome changes, and immunologic effects. Pre- and on-treatment tumor biopsies assess tumor microenvironment change. **Methods:** This 2 cohort study treats standard therapy refractory metastatic solid tumor patients with zeaxanthin (monotherapy cohort) or zeaxanthin and pembrolizumab (combination cohort). Combination cohort inclusion requires prior progression on a PD-1/L1 inhibitor. Oral zeaxanthin is administered daily with escalating doses (2 mg/kg to 10 mg/kg). The combination cohort escalates doses of zeaxanthin with a fixed dose of pembrolizumab (400 mg) infused every 6 weeks. Dose escalation utilizes a 3+3 design. Combination cohort dose level enrollment occurs after a zeaxanthin dose demonstrates no monotherapy DLT. Pharmacokinetic assessments occur at specified time points, Required large volume blood draws for pharmacodynamic analysis and optional tumor biopsies are obtained within 15 days prior to treatment initiation and at 6 weeks on treatment. Cohort 1 of zeaxanthin monotherapy (2 mg/kg daily) completed without DLT. Enrollment to monotherapy cohort 2 (zeaxanthin 4 mg/kg daily) and combination cohort 1 (zeaxanthin 2 mg/kg plus pembrolizumab 400 mg IV every 6 weeks) began November 2025 and are actively accruing patients. Clinical trial registry number: NCT05232409. (1) Bi et al. Evid. Based Compl. Alt. Med. (2013)12; (2) Xu et al. J Opthal (2015)10; (3) Zhang et.al. Cell Rep. Med. (2025)6. Clinical trial information: NCT05232409. Research Sponsor: Dr. Richard Rosen Cancer Research Fund.

TPS2697 **Poster Session**

Organ preservation strategy using dostarlimab for dMMR/MSI-H resectable solid tumors with whole-genome–based MRD monitoring (D-CURE: EPOC2401). First Author: Yuki Matsubara, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: Mismatch repair-deficient (dMMR)/microsatellite instability-high (MSI-H) solid tumors accumulate numerous genomic alterations that generate neoantigens, which are presented on MHC molecules and activate potent Th1 and cytotoxic T-cell responses. This heightened immunogenicity simultaneously induces adaptive immune resistance through PD-1/PD-L1 upregulation, providing a strong biological rationale for the effectiveness of immune-checkpoint inhibitors in dMMR/MSI-H tumors. Neoadjuvant immune-checkpoint inhibition is particularly effective in dMMR/MSI-H tumors because it leverages the intact tumor and lymphatic microenvironment to prime robust systemic antitumor immunity before surgical removal. Standard surgery for solid tumors varies widely depending on the cancer type, but it carries risks of functional impairment and postoperative morbidity. Therefore, nonoperative management (NOM) has emerged as a clinically meaningful strategy to preserve organ function and improve patients' quality of life. **Methods:** D-CURE is a multicenter phase II trial evaluating whether dostarlimab, an anti–PD-1 IgG4 humanized monoclonal antibody, can safely achieve clinical complete response (cCR) and enable NOM with organ preservation in patients with dMMR/MSI-H resectable solid tumors (excluding colorectal cancer). Patients will receive 9 cycles of dostarlimab (500 mg/body every 3 weeks). Observation with NOM will be offered to patients who achieve cCR or near-cCR. Patients undergoing NOM will be followed for up to 2 years from the date of enrollment. The primary endpoint is the 12-month cCR rate after dostarlimab. Key eligibility criteria are as follows: untreated malignancy (excluding colorectal cancer); dMMR/MSI-H confirmed in tissue or blood; age ≥18 years; ECOG PS 0–1; and clinical stage eligible for surgical resection, definitive radiotherapy, or definitive chemoradiotherapy according to the TNM 8th Edition. The target sample size of 80 was determined based on 90% power, a one-sided alpha of 5%, a threshold 12-month cCR rate of 38%, and an expected 12-month cCR rate of 56%. We also integrate personalized precise molecular residual disease (MRD) monitoring incorporating up to 1,000 tumor-specific alterations identified through whole-genome sequencing of tumor tissue, with serial ctDNA-based MRD assessment and parallel enrollment in the MONSTAR-SCREEN-3 study (UMIN000053975). Through this linkage, patients will also have access to the multi-omics platform, enabling spatial transcriptomics, bulk WES/WTS, plasma proteomics, and microbiome analyses to elucidate tumor-immune dynamics and comprehensively characterize treatment response and resistance. Enrollment of the D-CURE trial started in September 2025 and is ongoing at 12 facilities in Japan. Clinical trial information: jRCT2031250364. Research Sponsor: GlaxoSmithKline Research & Development Limited.

TPS2698 **Poster Session**

A phase II study of the DNA plasmid-based vaccine STEMVAC in patients with metastatic triple-negative breast cancer (mTNBC). First Author: Brie Chun, University of Washington, Fred Hutchinson Cancer Center, Seattle, WA

Background: Adding immune checkpoint inhibitors for the treatment of mTNBC improves the efficacy of traditional chemotherapy in select populations. In populations who are not predicted to benefit from PD-1 checkpoint inhibitors, a vaccine may sensitize Th1 cells against cancer-associated antigens to facilitate immune-mediated tumor killing. STEMVAC is a safe, immunogenic plasmid DNA-based vaccine encoding T-helper 1 (Th1) selective epitopes from five antigens (MDM2, YB1, SOX2, CDH3, CD105) associated with breast cancer stem cells and the epithelial-mesenchymal transition. In addition to direct cytotoxic effects directed against cancer cells, we have demonstrated that vaccine-induced Th1 cells secrete IFN-γ, which upregulates suppressor of cytokine signaling 1 (SOCS1), leading to slowed tumor growth and increased vulnerability to cytotoxic agents. Combining STEMVAC with chemotherapy could thus have synergistic effects leading to enhanced cancer sensitivity to treatment and possible eradication. **Methods:** The study (NCT07078604) includes adults with PD-L1 negative mTNBC receiving standard therapies inclusive of chemotherapy, antibody-drug conjugates, and oral PARP inhibitors in the first and second line. Eligible patients will have histologically-confirmed mTNBC, radiographically measurable disease by RECIST v1.1, and a lesion amenable to biopsy. Key exclusion criteria include concomitant B-cell malignancies, ongoing systemic steroid use, and known hypersensitivity reaction to GM-CSF. Participants receive intradermal STEMVAC 300mcg with 100mcg of GM-CSF given during the nadir period of standard of care chemotherapy. Participants receive three priming vaccines given every 21-28 days concurrent with chemotherapy, followed by booster doses at 6 and 9 months then every six months thereafter. The primary endpoints are 1) observance of immunogenicity to one of the five vaccine antigens, measured by interferon-gamma enzyme-linked immunospot assay, and 2) safety. Secondary endpoints include objective response rate, real-world PFS2, overall survival, and magnitude of immunogenicity. Exploratory endpoints include quantitative levels of CD8+ infiltrating lymphocytes and expression of genes associated with epithelial-mesenchymal transition before and after vaccine priming. Current status: This trial is recruiting patients, with up to 20 patients expected to be recruited across multiple sites. Safety data and preliminary outcomes will be reported as they become available. This trial aims to evaluate whether STEMVAC would achieve clinically relevant immunogenicity when administered concurrently with chemotherapy for the treatment of mTNBC. The trial will evaluate the safety and preliminary efficacy of this novel combination and explore tumor-immune microenvironment biomarkers to gain mechanistic insight. Clinical trial information: NCT07078604. Research Sponsor: Kuni Foundation.

TPS2699 **Poster Session**

A clinical study of a prototype DAA/TAA vaccine targeting MUC1 for immune interception and prevention in ductal carcinoma in situ. First Author: Emilia Diego, Division of Breast Surgical Oncology, University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Hypoglycosylated tumor MUC1 is a transmembrane glycoprotein, recognized by human T-cells and antibodies as a tumor-associated antigen. It is overexpressed in premalignant precursor lesions, including ductal carcinoma in situ (DCIS), serving as a potential potent DCIS rejection target. Vaccine-induced immune response to MUC1 may halt DCIS recurrence or progression to invasive disease and offer a future strategy for disease prevention in high-risk individuals. The hypothesis is MUC1 peptide vaccine is safe and immunogenic in patients with DCIS and the elicited systemic immune response will affect changes in the microenvironment of the DCIS from pro- to anti-tumor. Eligibility: Female, 18 years or older with biopsy proven ER+ DCIS with surgery planned as part of definite local therapy. Design: This single institution, open label, randomized phase I clinical trial (NCT06218303) is seeking 50 women with untreated ER+ DCIS confirmed on core needle biopsy (CNB). Patients are randomized 2:1 to the vaccine group. The vaccine is composed of a 100aa long MUC1 peptide corresponding to 5 tandem repeats of 20 amino acids from the MUC1 variable number of tandem repeats region (VNTR), admixed with the poly-ICLC adjuvant Hiltonol. The vaccine group receives the MUC1 peptide vaccine series pre-op (at 0, 2, and 10 weeks) with optional tamoxifen or an aromatase inhibitor (AI). The control group receives only optional tamoxifen or AI. All have surgery at 12 weeks. Research blood is drawn in the vaccine group at baseline and 2 weeks after each vaccine, and in the control group at baseline and at week 12. Tissue from the pre-treatment CNB and the post-treatment surgery are collected. An optional booster is available to vaccine responders 6 months post-surgery. Aims: The primary objective is to assess the immunogenicity of the MUC1 vaccine in ER+ DCIS patients prior to surgery. The secondary objective is to assess the safety and feasibility of the MUC1 vaccine in ER+ DCIS patients prior to surgery. The exploratory objective is to characterize peripheral MUC1-specific effector T-cells, regulatory T-cells and myeloid-derived suppressor cells (MDSC) at baseline and after vaccination. Changes in features of the tumor microenvironment and peripheral immunity at baseline and after vaccination may also be explored. **Methods:** Sample size/power: Assuming a one-sided type I error $\alpha \leq 0.05$ and the rate of patients having a $\geq 2\times$ change in anti-MUC1 IgG 1 is 35% in the vaccine arm and 2% in the control arm, a sample sizes of n=32 and 18 respectively in each arm will yield 88% power. With a dropout of up to 3 patients in each arm, the remaining sample size will still yield power of 82%. Statistical analysis: Fisher's exact test will be performed at the one-sided α=0.05 for the primary immunogenicity endpoint for comparing the experimental arm to the control arm. Clinical trial information: NCT06218303. Research Sponsor: Breast Cancer Research Foundation.

TPS2700 **Poster Session**

A phase 1 trial of the oncolytic virus SVV-001 with nivolumab and ipilimumab in patients with high-grade neuroendocrine neoplasms. First Author: Chinmay Jani, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL

Background: Poorly differentiated neuroendocrine carcinomas (NECs), including small cell and large cell neuroendocrine tumors, and grade 3 neuroendocrine tumors (NETs) represent a highly aggressive disease collectively classified as high-grade neuroendocrine neoplasms (NENs). These tumors are marked by rapid tumor growth, early dissemination, genomic instability, and poor outcomes. Despite initial sensitivity to chemotherapy and radiotherapy, relapse rates remain high, and immune checkpoint inhibitors (ICIs) have demonstrated limited activity, highlighting a substantial unmet therapeutic need. Seneca Valley Virus (SVV-001) is a novel oncolytic picornavirus that has demonstrated synergistic antitumor activity with ICIs in preclinical models. Additionally, SVV-001 has shown a favorable safety profile and the ability to reverse ICI resistance in vivo, supporting its evaluation in combination with nivolumab + ipilimumab. **Methods:** This is an investigator-initiated, phase 1, dose-escalation and cohort-expansion study evaluating intratumoral SVV-001 in combination with nivolumab + ipilimumab in patients with histologically confirmed high-grade NENs who have progressed on at least one prior line of standard-of-care therapy. Eligible patients must have at least one lesion suitable to repeated intratumoral injections of SVV-001 (up to 6 injections every two weeks). The trial was activated in March 2025 at Sylvester Comprehensive Cancer Center, with enrollment currently ongoing and a planned accrual of up to 36 patients. Part 1 used a standard 3+3 dose-escalation design. Enrollment in the first three cohorts (Part 1A), evaluating single-dose SVV-001 in combination with nivolumab and ipilimumab, is complete with no dose-limiting toxicities observed. Enrollment into cohort 4 (Part 1B), which will evaluate multiple doses of SVV-001 (up to 6 injections) is planned to begin in February 2026 followed by Cohort 5. Part 2 consists of a cohort-expansion phase in which up to 6 additional patients will be treated at the optimal recommended phase 2 dose (RP2D) of SVV-001. The primary objective is to determine the maximum tolerated dose (MTD) and/or RP2D. Secondary objectives include radiographic progression-free survival (PFS), overall response rate (ORR), duration of response, clinical benefit rate (CBR), and safety. Correlative studies will assess viral kinetics, including viral release and viral load in plasma, as well as Tumor Endothelial Marker 8 (TEM8), a potential biomarker of SVV-001 sensitivity and its association with efficacy signals. Additional exploratory analyses will characterize the tumor immune microenvironment and gut microbiome markers in the dose-expansion cohort. ClinicalTrials.gov Identifier: NCT06889493. Clinical trial information: NCT06889493. Research Sponsor: None.

3000 Oral Abstract Session

DXC006, a first-in-class CD56-targeting antibody-drug conjugate, in advanced solid tumors: A first-in-human, phase I dose escalation clinical trial. First Author: Hongyun Zhao, Cancer center, Sun Yat-sen University, Guangzhou, China

Background: DXC006 is an antibody-drug conjugate of a humanized anti-CD56 antibody linked to the topoisomerase I inhibitor CPT113 with DAR=4 through a cleavable peptidyl bis-linker by CrossConju technology. DXC006 demonstrated strong antitumor activity *in vivo* and *in vitro*, here we report the safety and preliminary efficacy of first-in-human phase I trial of DXC006. **Methods:** Patients with metastatic/locally advanced solid tumors after at least one line of systemic standard therapy were enrolled. For dose escalation (D-ESC), DXC006 was administered intravenously at doses of 1.2, 2.4, 4.8, 6.0mg/kg Q2W or 6.0, 7.2 mg/kg Q3W with BOIN design and 3+3 design. A subset of pts was enrolled into dose-expansion (D-EXP) at recommended dose regimen. The primary objectives were to evaluate the safety and tolerability (dose limiting toxicities, DLTs; maximum tolerated dose, MTD) of DXC006. **Results:** Data cutoff at December 26th, 2025, 72 patients were enrolled and received at least one dose(D-ESC n=16,D-EXP n=56) , including SCLC (n=44), lung adenocarcinoma (n=11), lung squamous cell carcinoma (n=3), neuroendocrine neoplasm (n=14). No DLTs occurred and MTD was not reached. D-EXP was carried out at 4.8mg/kg Q2W and 6.0mg/kg Q3W regimens. Treatment related adverse events (TRAEs) rate (all grade/≥G3) was 97.2% and 27.8%, TOP5 most common TRAEs (all grade/≥G3) were decreased appetite (54.2%/0%), nausea (52.8%/0%), anemia (48.6%/20.8%), asthenia (37.5%/1.4%), sensory disturbance (33.3%/0%). No interstitial lung disease (ILD) was observed. TRAEs led to dose interruption/discontinuation were observed in (23.6%/1.4%) of the patients. RP2D is 6.0mg/kg Q3W. Totally, 59 patients were eligible for efficacy analysis. For all patients, the objective response rate (ORR) and disease control rate (DCR) were 52.5 % and 81.4% (including confirmed and pending confirmation PR); for SCLC patients, were 69.4% and 91.7%; for lung adenocarcinoma, were 45.5% and 72.7% (details in table). Encouraging anti-tumor activity was observed for DXC006 treatment in SCLC at 2nd line (ORR 85.7%, confirmed 64.3%). PK, PD and PFS results will be updated in the upcoming meeting. **Conclusions:** DXC006 demonstrated a manageable safety profile and adequate tolerability, and showed encouraging efficacy in pretreated advanced solid tumors, especially in SCLC. Clinical trial information: NCT06224855. Research Sponsor: Hangzhou DAC Biotechnology Co., Ltd.

Phase I study of BL-M14D1, a novel DLL3-directed antibody-drug conjugate (ADC), in patients with locally advanced or metastatic small-cell lung cancer (SCLC), neuroendocrine carcinoma (NEC), and other solid tumors. First Author: Wei Li, Shanghai East Hospital, Shanghai, China

Background: BL-M14D1 is a novel DLL3-directed ADC with a potent topoisomerase I inhibitor Ed-04. Results for safety and efficacy from a phase I study on BL-M14D1 in patients with locally advanced or metastatic (LA/M) SCLC and NEC are presented. **Methods:** Patients who had LA/M solid tumors were enrolled in dose escalation and dose expansion phase and treated with BL-M14D1 at 0.66, 2.0, 3.5, 4.0, 4.5, 5.0, and 6.0mg/kg on Day 1 every 3 weeks (D1 Q3W). SCLC and NEC patients enrolled in dose expansion phase were treated at 4.0 and 4.5mg/kg D1 Q3W. **Results:** As of Nov 30, 2025, a total of 127 patients were enrolled, including 87 SCLC and 40 NEC. Median prior line of therapy was 2 (range 1-5). Treatment-related AEs (TRAEs) rate was 98.4% and grade≥3 TRAEs rate was 74.0%. The most frequent grade≥3 TRAEs were hematologic, including thrombocytopenia (54.3%), neutropenia (53.5%), leukopenia (46.5%) and anemia (32.3%), which were able to be effectively managed with standard supportive measures including dose reductions, as demonstrated by a low rate (1.6%) of TRAEs leading to discontinuation. One grade 3 ILD and one treatment-related death was reported. Efficacy data at 4.0 and 4.5mg/kg was presented below. BL-M14D1 has demonstrated a promising efficacy with an ORR/cORR of 71.1%/57.8% and mPFS of 7.2 months in heavily pre-treated SCLC. Furthermore, BL-M14D1 has shown encouraging activity in other gastrointestinal and gynecological NECs. **Conclusions:** BL-M14D1 has demonstrated promising antitumor activity with a tolerable safety profile at dose levels of 4.0mg/kg and 4.5mg/kg D1 Q3W in heavily pretreated patients with SCLC and NEC, supporting further clinical development of BL-M14D1 in SCLC and other less common NECs. Phase III studies assessing BL-M14D1 in SCLC and NEC are in preparation. Clinical trial information: NCT06505824. Research Sponsor: Baili-Bio (Chengdu) Pharmaceutical Co., Ltd.

†Sites of NEC included cervix, esophagus, stomach and others.
*Efficacy analysis included pts at 4.0 and 4.5 mg/kg who received BL-M14D1 and had at least one post-baseline scan.

3002 Oral Abstract Session

First-in-human study of SYS6043, a novel B7-H3–targeting antibody-drug conjugate, in patients with advanced pan-tumor malignancies. First Author: Li Zhang, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: B7-H3, a tumor-associated immune checkpoint, is broadly overexpressed in multiple solid tumors and associated with aggressive disease biology and treatment resistance. SYS6043, a novel ADC targeting B7-H3, is designed to selectively deliver a cytotoxic payload to B7-H3 expressing tumors. Preclinical trials showed potent antitumor activity across diverse solid tumor models. Here, we report safety and efficacy results from a phase 1/2 trial of SYS6043 in patients with advanced solid tumors. **Methods:** Eligible patients (18–75 years) had advanced solid tumors refractory to or progressing after standard therapies. The study included a phases 1 dose-escalation and PK expansion phase, followed by a phase 2 cohort expansion. Phase 1 used a BOIN design to evaluate SYS6043 at a dose of 1.2-10.0 mg/kg Q3W and 4.0-6.0 mg/kg Q2W, with PK expansion at selected doses. Phase 2 evaluated SYS6043 at 8.0 mg/kg Q3W and 6.0 mg/kg Q3W and Q2W across tumor-specific cohorts. Primary endpoints were safety, tolerability, and determination of the RP2D in Phase 1, and objective response rate (ORR) in Phase 2. **Results:** As of November 28 2025, 502 patients were enrolled, including ovarian cancer (OC, *n*= 68), small cell lung cancer (SCLC, *n*= 57), breast cancer (BC, *n*= 55), cervical cancer (CC, *n*= 42), nasopharyngeal carcinoma (NPC, *n*= 40), non-squamous non-small lung cancer (nsq-NSCLC, *n*= 34), endometrial cancer (EC, *n*= 21), and other solid tumors (*n*= 185). Dose-limiting toxicities (grade 3 gastrointestinal disease, and grade 4 febrile neutropenia) occurred at 10.0 mg/kg Q3W. Treatment-related adverse events (TRAEs) occurred in 94.2% of patients, with ≥grade 3 TRAEs in 28.5%. The most common TRAEs were anemia (52.0%), nausea (44.4%), fragile (42.8%), leukemia (41.6%), neutropenia (36.9%), decreased appetite (35.3%), and hypoalbuminemia (25.3%). Efficacy analyses focused on Q3W cohorts. SYS6043 demonstrated rapid and deep antitumor activity across multiple tumor types. In heavily pretreated SCLC (*n*= 50), ORR was 64.0% (95% CI, 49.2-77.1) with DCR of 92.0% (95% CI, 80.8-97.8). At 6 mg/kg Q3W (*n*= 28), ORR reached 75.0% (95% CI, 55.1-89.3), including one complete response. In OC, ORR and DCR were 46.2% and 87.2%, respectively with median PFS of 5.6 months at 6 mg/kg Q3W. Notably high response rates were also observed in BC (ORR 83.8%, DCR 100%), nsq-NSCLC (ORR, 57.1%), CC (ORR, 38.5%), NPC (ORR, 37.9%), and EC (ORR, 30.0%), indicating broad and consistent antitumor activity. **Conclusions:** SYS6043 demonstrated a manageable safety profile and robust, cross-tumor antitumor activity in a large population of patients with advanced solid tumors. The magnitude and consistency of responses across multiple histologies, including treatment-refractory tumors such as SCLC, support SYS6043 as a promising therapeutic candidate warranting further clinical and translational investigation. Clinical trial information: ChiCTR2400094683. Research Sponsor: CSPC Megalith Biopharmaceutial Co., Ltd.

3003 Oral Abstract Session

T-Bren (BL-M07D1) in patients with recurrent or metastatic (R/M) ovarian cancer: Results from two phase II studies. First Author: Gong-Yi Zhang, Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China

Background: T-Bren is a HER2-directed antibody-drug conjugate (ADC) consisting of an anti-HER2 monoclonal antibody linked to a potent topoisomerase I inhibitor (Ed-04). In phase I studies, T-Bren demonstrated encouraging anti-tumor activity with a manageable safety profile in patients (pts) with solid tumors. Results of safety/efficacy from two phase II studies in pts with R/M ovarian cancer (OC) are presented. **Methods:** Two studies evaluated T-Bren as monotherapy in pts with R/M platinum-resistant (disease progression within 6 months of the last dose of platinum-based chemotherapy) and platinum-sensitive OC. Pts with R/M OC were treated at 3.8mg/kg or 4.4mg/kg D1 Q3W. Primary endpoints include ORR and RP2D. Pts were selected for HER2 expression (ultra-low/1+/2+/3+). **Results:** As of Nov 30, 2025, a total of 65 pts were enrolled at 3.8 (N = 51), or 4.4mg/kg (N = 14) D1Q3W. Of all pts, 28 (43.1%) pts previously received ≥3 lines of therapy. The most common grade 3 and above hematologic TRAEs were thrombocytopenia (41.5%), leukopenia (35.4%), neutropenia (35.4%), and anemia (29.2%); the most common grade 3 and above non-hematologic TRAEs were asthenia (6.2%), lymphocyte count decrease (6.2%). Grade 3 and above TRAEs, which were predominantly hematologic in nature, were able to be effectively managed with standard supportive measure including dose reductions, as demonstrated by the TRAE leading to discontinuation rate of 3.1%. No ILD was observed. No new safety signals were identified. Median follow-up was 7.8 mo. Among pts at 3.8mg/kg D1 Q3W, confirmed ORR (cORR) was 88.9% in platinum-sensitive OC and 47.5% in platinum-resistant OC. mPFS had not reached and 9-mo PFS rate was 85.7% in platinum-sensitive OC and 61.2% in platinum-resistant OC. Efficacy results are summarized in the table below. **Conclusions:** T-Bren has demonstrated promising anti-tumor activity with a manageable safety profile in heavily pre-treated pts with R/M OC. Dose 3.8mg/kg D1 Q3W was chosen as the RP3D. Phase III study of platinum-resistant OC is in preparation. Clinical trial information: NCT06031584; NCT06131450. Research Sponsor: Baili-Bio (Chengdu) Pharmaceutical Co., Ltd.

Analysis of spatial atlas of ADC targets in immunotherapy-treated NSCLC to link compartment-specific target expression with tumor immune contexture, clinical outcome, and on-treatment remodeling. First Author: Jean-Philippe Guegan, ImmuSmol, Bordeaux, France

Background: The spatial distribution, co-expression patterns, immune contexture associations, and on-treatment evolution of ADC targets in NSCLC is unknown. **Methods:** The samples of 100 NSCLC patients treated with PD-1/PD-L1–based immunotherapy (STING NCT04932525) were analyzed using multiplex immunofluorescence with three 7-plex panels assessing ADC targets (Claudin18.2, TROP2, B7-H3, B7-H4), receptor co-expression (HER2, EGFR, MET, STEAP2), and immune contexture (CD8, PD-1, TIM3, LAG3, TIGIT), with PanCK and CD45 for compartment assignment. Digital pathology enabled single-cell segmentation into tumor (PanCK+), stromal, and immune (CD45+) compartments. Immune contexture was defined as Desert, Excluded, or Infiltrated by CD8 distribution. ADC target expression was quantified as the proportion of PanCK+ tumor cells expressing each target or combination. Associations with objective response (ORR), progression-free survival (PFS), and overall survival (OS) were assessed. Paired baseline/on-treatment biopsies (n = 21 pairs) evaluated treatment-induced remodeling. **Results:** Spatial profiling quantified 30 tumor-cell ADC target phenotypes. Across NSCLC, epithelial target coverage was broad, with $>$ 80% of tumor cells expressing EGFR or MET and $>$ 60% co-expressing both. Co-expression patterns were histology-dependent: EGFR/MET ($\pm$HER2) predominated in adenocarcinoma, whereas TROP2/B7-H3 co-expression was enriched in squamous carcinoma. Immune contexture shaped the ADC landscape: Infiltrated tumors showed higher tumor-cell fractions expressing EGFR, MET, TROP2, HER2, STEAP2, and B7-H3 compared with Desert tumors (all $p \leq 0.01$), while PanCK+/B7-H4 and PanCK+/CLDN18 were not contexture-associated. Clinically, B7-H4 showed a striking compartment-specific association with outcome. High abundance of B7-H4–expressing immune/stromal cells was the only phenotype replicated across ORR, PFS, and OS (stromal B7H4+: ORR 65.0% vs 38.6%, p = 0.010; PFS 12.0 vs 4.0, p = 0.013; OS 36.4 vs 13.1, p = 0.016). In contrast, tumor-cell B7-H4 predicted resistance and poor survival (tumoral B7H4+: PFS 3.5 vs 10.2, p = 0.007; OS 10.9 vs 35.6, p = 0.047). On treatment, paired biopsies demonstrated target remodeling, with increased B7-H3 expression and a concordant reduction of tumor CLDN18 by composition and membrane intensity. **Conclusions:** ADC target abundance and co-expression in NSCLC tumor cells are immune-contexture dependent and dynamically remodeled under ICI. Distinct, histology-specific co-expression patterns inform rational mono- and dual-ADC strategies. A novel, clinically actionable finding is the opposite prognostic impact of B7-H4 by spatial compartment, supporting spatially resolved biomarkers and histology- and timepoint-aware ADC$\pm$ICI selection for precision treatment in NSCLC. Research Sponsor: None.

3005 **Oral Abstract Session**

Clinical utility of discordances between histomorphology and molecular biomarkers in precision oncology. First Author: Gil Shamai, Technion Israel Institute of Technology, Haifa, Israel, Israel

Background: Conventional molecular biomarkers guide treatment selection in precision oncology, yet therapeutic benefit remains variable even within biomarker-defined populations. Deep learning (DL) models can infer biomarker status from hematoxylin and eosin (H&E) histopathology, but systematic discordances arise between conventional biomarker assays and their histomorphology-based (HM) predictions. We hypothesized that such discordances reflect biologically meaningful tumor functional states rather than model error and may have clinical relevance. **Methods:** DL models were trained to predict 15 clinically relevant biomarkers from H&E images across six cancer types using public datasets. Discordant cases, defined as disagreement between assay-based biomarker labels and their DL prediction from H&E, were quantified and analyzed for alignment with functional gene expression states and clinical outcomes. Clinical utility was assessed in two landmark randomized trials: FINHER (HER2 prediction; N = 1010; trastuzumab randomized in HER2+ patients), and TAILORx (Oncotype DX recurrence score [RS] prediction; N = 10,273; chemotherapy randomization within RS 11–25). Adjusted Cox models tested added prognostic value and treatment beneft interactions. Primary endpoint was distant recurrence. **Results:** Models achieved strong performance for predicting the biomarkers (median AUC 0.78; range 0.65–0.87). Discordance rates ranged from 8% (MSI in colon) to 32% (KRAS in lung). In discordant cases, HM predictions correlated more strongly with functional gene expression states than the biomarker status they were trained to predict (mean Spearman r = 0.52 vs 0.31; $p < 0.001$). In FINHER, predicted HER2 status added prognostic value beyond HER2 status (p = 0.01) and predicted trastuzumab benefit in HER2+ patients (p-interaction = 0.026). In HER2+ patients, trastuzumab benefit was observed in those predicted as HER2+ (HR = 0.35, 95% CI: 0.15–0.83), but not in those predicted as HER2- (HR = 1.17, 95% CI: 0.45–3.02). In TAILORx, predicted RS added prognostic value over true RS in the no-chemo group (p = 0.005) and showed treatment interaction beyond RS within RS 11–25 (N = 1629; p-interaction = 0.021), as well as when restricted to postmenopausals (p = 0.029). Discordant patients (RS 11–25 predicted as RS $>$ 26) derived chemotherapy benefit (HR = 0.30, 95% CI: 0.13–0.77), whereas those predicted as RS $<$ 26 did not (HR = 0.95, 95% CI: 0.71–1.29). **Conclusions:** Discordances between molecular biomarkers and HM predictions are not random errors but reflect underlying tumor functional states. HM biomarkers may capture relevant information missed by standard assays that can improve therapeutic benefit prediction. This framework enables reinterpretation of DL pathology predictions, supports integrating H&E models to complement biomarkers, and enables derivation of functional information without outcome data. 3006 **Oral Abstract Session**

Clinical activity and safety of RNK08954 in advanced non–small cell lung cancer (NSCLC) patients with *KRAS* G12D mutation (NCT06667544). First Author: Zhengbo Song, Phase I Clinical Trial Ward, Zhejiang Cancer Hospital, Hangzhou, China

Background: KRAS G12D is the most prevalent subtype of KRAS mutations across solid tumors. RNK08954 is a potent and selective KRAS G12D small molecule oral inhibitor. It inhibited proliferation of KRAS G12D-mutant cells and demonstrated significant tumor regressions in mouse xenograft models. Here we report the results of RNK08954 from Phase 1 first-in-human study. **Methods:** This ongoing multicenter open-label trial of RNK08954, comprises of: Phase 1a dose-escalation (U-BOIN design, 5 dose levels: 200, 400, 800, 1000 and 1200 mg RNK08954 single agent QD) and Phase 1b dose optimization and expansion cohorts (NSCLC, Pancreatic, and other tumor types). Key endpoints were determining the recommended doses for expansion (RDE), safety, tolerability, antitumor activity (objective response rate (ORR), disease control rate (DCR), duration of response (DoR), progression free survival (PFS)), pharmacokinetics and pharmacodynamics. Patients (pts) enrolled into the study had solid tumors not amenable to standard therapy; 0 or 1 ECOG PS; and KRAS G12D mutation. **Results:** At data cutoff (Jan 20, 2026), 106 pts were enrolled, with 47 pts presenting with NSCLC. The median age was 65 years, and 91.5% of pts had ECOG 1. Prior lines of therapy ranged between 1 and 3, with a median of 14 mo since NSCLC diagnosis. The ORR was 38.5% (15/39; 95% CI: 23.4, 55.4), DCR was 94.9% (37/39; 95% CI: 82.7%, 99.4%), median DoR was not reached (NR) at the time of analysis (Q1, Q3: 4.8, NR) and median PFS will be reported with mature data. ctDNA analysis demonstrated correlation with clinical benefits. RNK08954 demonstrated a near-dose dependent exposure across dose levels. Both 1000 and 1200 mg were chosen for RDE, and the recommended Phase 2 is considered as 1200 mg QD. Overall, treatment was tolerated, with diarrhea (78.7%), nausea (61.7%) and vomiting (55.3%) being the most frequent treatment related events (TRAEs) and were mainly Grade 1. Grade 3 TRAEs occurred in 23.4%, with diarrhea most frequent TRAEs (10.6%). No Grade 3 or higher transaminase elevation (ALT/AST) was observed, only one patient experienced Grade 3 neutropenia.There were no fatal events. Further updated results will be presented at the meeting. **Conclusions:** RNK08954 was well tolerated and displayed promising antitumor activity in pts with KRAS G12D-mutant NSCLC. The study supports further evaluation either as monotherapy or in combination with standard of care and/or novel agents. Clinical trial information: NCT06667544. Research Sponsor: None.

3007 **Oral Abstract Session**

Phase I/IIa study of DN022150, a novel selective noncovalent small molecule KRAS G12D inhibitor in patients with advanced KRAS G12D–mutant solid tumors. First Author: Yiyi Yu, Zhongshan Hospital, Fudan University, Shanghai, China

Background: The KRAS G12D mutation is ranks among the most common RAS mutations across human cancers and is closely linked to poor clinical outcomes. DN022150 is a novel highly selective KRAS G12D inhibitor, that exerts potent antitumor effect by specifically binding to the switch-II pocket of the mutant KRAS G12D protein, this binding mechanism blocks the interaction of GDP and GTP with the mutant protein, thereby abrogating activation of the downstream of the RAS-MAPK signaling pathway. We report preliminary findings from the first-in-human study of DN022150 in patients with advanced KRAS G12D-mutant solid tumors. **Methods:** This Phase I/IIa study evaluates the safety, tolerability, pharmacokinetics (PK), and efficacy of DN022150 in patients with locally advanced or metastatic solid tumors harboring KRAS G12D mutations who have progressed following prior standard therapies. The study includes three sequential parts: dose escalation, dose expansion, and indication exploration. During dose escalation, patients receive fixed doses of DN022150. Based on integrated analysis of safety, tolerability, PK, and efficacy data from escalation phase, approximately 1-3 dose/frequency cohorts will be selected for the subsequent dose-expansion phase. The primary objective is to evaluate the safety, tolerability, and preliminary antitumor activity of DN022150 in patients with KRAS G12D-mutated advanced solid tumors. **Results:** As of January 22, 2026, a total of 56 patients were enrolled. Among them, 83.9% (47/56) had an ECOG PS of 1 and 66.1% (37/56) diagnosed with pancreatic cancer. Approximately 80% had received $\geq$2 prior lines of systemic therapy. Safety analysis included 49 participants (dose levels: 20-650 mg). Notably, no dose-limiting toxicities occurred across all dose levels. Grade $\geq$3 TEAEs were observed in 44.9% (22/49) of patients, with TRAEs in 30.6% (15/49). No grade 4-5 TRAEs were documented. TRAEs led to dose delays in 14.3% (7/49) of patients and treatment interruptions in 16.3% (8/49). The most common grade $\geq$3 TRAEs ($\geq$5%) were neutropenia, anemia, and leukopenia. Tumor assessments were conducted every 8 weeks ($\pm$7 days). Among the 31 evaluable patients, treated at dose levels of 200 mg to 650 mg, an impressive 96.8% (30/31) achieved target lesion reduction at first post-baseline assessment, including 71% (22/31) with $\geq$20% reduction. ORR was 37.5% (3/8) at 450 mg and 31.3% (5/16) at 650 mg, with DCR of 87.5% (7/8) and 93.8% (15/16). **Conclusions:** DN022150 demonstrated favorable safety and tolerability profiles in patients with KRAS G12D-mutated advanced solid tumors, with no dose-limiting toxicities observed and manageable TRAEs. The agent showed potent antitumor activity, confirming its precise targeting of the KRAS G12D mutation. These results position DN022150 as a promising novel therapy for this molecularly defined population. Clinical trial information: CTR20242749. Research Sponsor: None.

3008 Oral Abstract Session

Preliminary efficacy of GFH375 in patients with advanced cholangiocarcinoma or colorectal cancer harboring KRAS G12D mutation. First Author: Lingjun Zhu, Department of Oncology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China

Background: Kirsten rat sarcoma (KRAS) G12D is the most prevalent RAS mutation in human cancers, accounting for 10.6-19.2% and 5.8-10.8% of cases in colorectal cancer (CRC) and cholangiocarcinoma (CCA), respectively. Currently, the later-line therapies for metastatic CCA and CRC remain very limited. The KRAS G12D mutation is associated with poor prognosis and confers resistance to conventional chemotherapy. GFH375, a potent, selective, orally bioavailable KRAS G12D inhibitor, has demonstrated antitumor efficacy in pancreatic cancer and non-small cell lung cancer. Here we report the preliminary efficacy results of GFH375 in patients (pts) with advanced KRAS G12D mutant CCA and CRC. **Methods:** This is a phase I/II study (NCT06500676) evaluating the safety, tolerability, pharmacokinetics and efficacy of GFH375 in pts with advanced solid tumors harboring KRAS G12D mutations. Pts with locally advanced or metastatic CCA and CRC who had failed prior therapies were also enrolled. Tumor assessments were performed every 6 weeks during the first 48 weeks, and every 12 weeks thereafter. All efficacy endpoints, including objective response rate (ORR), disease control rate (DCR) and progression-free survival (PFS) were evaluated according to RECIST v1.1. Circulating tumor DNA (ctDNA) samples were collected at baseline and at the end of treatment for exploratory analyses. **Results:** As of 31 Oct 2025, twenty CCA and 41 CRC pts were treated with GFH375 once daily (400, 600 or 750 mg). Among the CCA pts (median age: 59.5 yrs; 80.0% male), 17 (85.0%) had metastatic disease at baseline, and the median prior lines of therapy were 2 (range: 1-6). ORR was 35.0% (7/20), and DCR was 95.0% (19/20). Nine out of 12 pts with stable disease (SD) had tumor shrinkage. Median PFS was 6.3 months, and median overall survival (OS) was not reached. Among those CRC pts (median age: 56 yrs; 61.0% male), all had metastatic disease at baseline, and the median prior lines of therapy were 3 (range: 1-6). Among 35 pts who had at least one post-treatment tumor assessment, ORR was 11.4% (4/35), and DCR was 77.1% (27/35). Median PFS was 4.1 months and median OS was not reached. Baseline ctDNA results were available in 19 CCA pts and 36 CRC pts. KRAS G12D mutations were detected in 14 (73.7%) CCA pts and 31 (86.1%) CRC pts. The common co-mutated genes (≥15%) in CCA were TP53, BCL2L11 and APC, while in CRC were TP53, APC, RUNX1, SMAD4 and PIK3CA. The safety profile in the 61 pts was similar to that of the whole population as previously reported. The most common treatment-related adverse events (TRAEs) (≥30%) included diarrhea, nausea, vomiting, aspartate aminotransferase increased, anemia and decreased appetite. **Conclusions:** GFH375 monotherapy has demonstrated promising antitumor activities in heavily treated pts with CCA and CRC. GFH375 monotherapy in CCA and in combination with other anti-tumor therapies for CRC is under development. Clinical trial information: NCT06500676. Research Sponsor: GenFleet Therapeutics (Shanghai) Inc.

Integrin $\alpha_v\beta_3$-targeted radionuclide therapy with ^{177}Lu-AB-3PRGD$_2$ in multiple advanced metastatic solid tumors: A prospective, single-arm, single-center, investigator-initiated clinical trial. First Author: Hao Fu, The First Affiliated Hospital of Xiamen University, Xiamen, Fujian, China

Background: Tumor angiogenesis drives progression and metastasis in solid malignancies. Integrin $\alpha_v\beta_3$ is selectively overexpressed on multiple tumor cells and neovasculature with limited normal tissue expression, offering a promising therapeutic target. Our previous dose-escalation study investigated the safety and maximum tolerated dose of the integrin $\alpha_v\beta_3$-targeted radiopharmaceutical ^{177}Lu-AB-3PRGD$_2$. Building on this foundation, the current study aims to evaluate its therapeutic efficacy in patients with various advanced metastatic solid tumors. **Methods:** In this prospective, single-arm, single-center investigator-initiated clinical trial, eligible patients had histologically confirmed advanced metastatic solid tumors with documented progression after exhaustion of standard systemic therapies. Tumor integrin $\alpha_v\beta_3$ expression was confirmed by ^{68}Ga-3PRGD$_2$ PET/CT imaging. Patients received up to four cycles of ^{177}Lu-AB-3PRGD$_2$ at 3.7 GBq per cycle. The primary endpoint was ORR by RECIST 1.1. The secondary endpoints included DCR, PFS, OS, and safety. The sample size was calculated based on the primary endpoint of ORR. Assuming a null ORR of 10% and an alternative ORR of 30%, a one-sided binomial test with a significance level (α) of 0.05 and 80% power required approximately 20 evaluable patients. **Results:** From December 2023 to December 2025, 20 patients were enrolled. Of these, 5 received three treatment cycles and 5 received four cycles. The median age was 62 years (range 38–75) and 30% were female. Tumor types included radioiodine-refractory thyroid cancer (20%), breast cancer (15%), lung cancer (10%), cholangiocarcinoma (10%), renal cancer (10%), and others. At baseline, 65% of patients had ECOG performance status ≥2. Among 13 patients received ≥ 2 cycles of treatment, the ORR was 23% (3/13) and DCR was 92% (12/13), including 3 PR and 9 SD. With a median follow-up of 11.9 months, median PFS was 7.3 months and median OS was 18.5 months. Patients achieving disease control had significantly longer PFS and OS compared to those with progressive disease ($P<$ 0.001). Dosimetry analysis, available for 18 patients (90%), showed a mean tumor absorbed dose of 6.8 ± 5.4 Gy/GBq. Grade 3/4 treatment-related adverse events occurred in 20% of patients (4/20), primarily hematologic toxicities including thrombocytopenia (n = 4), leukopenia (n = 2), and anemia (n = 2). **Conclusions:** Integrin $\alpha_v\beta_3$-targeted radionuclide therapy with ^{177}Lu-AB-3PRGD$_2$ demonstrated promising efficacy in disease control and tumor response, and it was generally well tolerated in patients with advanced metastatic solid tumors. These findings justify further investigation in prospective, multicenter, randomized clinical trials. Clinical trial information: NCT06375564. Research Sponsor: None.

3010 Rapid Oral Abstract Session

Phase Ib results from the phase Ib/II study of [^{177}Lu]Lu-DOTA-TATE in combination with standard of care as a first-line treatment for pts with extensive-stage small cell lung cancer. First Author: Stephen V. Liu, Department of Medical Oncology, Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC

Background: Most pts with newly diagnosed extensive-stage small cell lung cancer (ES-SCLC) relapse after initial response to standard of care (SOC; platinum/etoposide + anti–programmed death-ligand 1 [PD-L1] therapy); novel combination strategies are needed. This Phase Ib/II study (NCT05142696) assessed [^{177}Lu]Lu-DOTA-TATE (^{177}Lu-DOTATATE) – a radioligand therapy with high affinity for somatostatin receptor 2 (SSTR2; a poor prognostic biomarker expressed in ~50% of SCLC tumors) – plus SOC. Here, we report Phase Ib data (cutoff 20 Nov 2025). **Methods:** Phase Ib was a dosage escalation study to determine the recommended dosage (RD) of ^{177}Lu-DOTATATE – alongside carboplatin AUC 5 + etoposide 100 mg/m^2 + anti–programmed cell death protein 1 (PD-1)/PD-L1 therapy (pre/post protocol amendment: tislelizumab 200 mg/atezolizumab 1200 mg, respectively) Q3W in the induction phase, and alongside anti–PD-1/PD-L1 therapy Q3W in the maintenance phase – in pts aged ≥18 y with newly diagnosed SSTR+ (by PET/CT) ES-SCLC. Cohorts of 3–6 pts were enrolled to increasing dosage levels (DLs) of ^{177}Lu-DOTATATE (backfill allowed to ≤10 pts); escalation was guided by dosage-limiting toxicity (DLT) rate (Bayesian Optimal Interval design) and other safety data. The primary endpoint was DLTs (^{177}Lu-DOTATATE–related adverse events within the 42-day DLT period). **Results:** Of 57 pts screened, 29 received treatment (median [range] age 62 [43–73] y; white 89.7%; male 44.8%; ECOG PS 0/1/2 37.9%/58.6%/3.4%; smoking history 100%; bone/brain/liver metastases 51.7%/13.8%/48.3%); 93.1% completed the induction phase (DL1 [3.7 GBq] 9/9; DL2a [5.55 GBq] 11/11; DL3a [7.4 GBq] 7/9). Median treatment duration between first/last dosage and cutoff was 14.2/9.4 months. For ^{177}Lu-DOTATATE, median (range) number of doses was 4.0 (1.0–7.0), duration was 4.1 (1–6) months, and cumulative activity was 22.7 (7.1–44.4) GBq. There were no DLTs in 17 evaluable pts. The table reports safety and preliminary efficacy data. **Conclusions:** The observed safety profile was consistent with expected toxicity; the RD for Phase II was 7.4 GBq. Clinical trial information: NCT05142696. Research Sponsor: Novartis Pharmaceuticals.

3011 Rapid Oral Abstract Session

An open-label, first-in-human study of SKB500 in patients with locally advanced or metastatic solid tumors. First Author: Xueying Zhang, Department of Internal Medicine III, Jilin Provincial Cancer Hospital, Changchun, China

Background: SKB500 is an antibody drug conjugate (ADC) composed of an antibody targeting the B7 homolog 3 (B7-H3), which is overexpressed in many types of solid tumors, conjugated to a topoisomerase I inhibitor payload via a cleavable pyrimidine-tripeptide linker. We hereby report initial results of the FIH study (NCT06736327). **Methods:** This phase 1 study comprised dose-escalation, dose-expansion, and indication-expansion phases to evaluate the safety, tolerability, pharmacokinetics, and efficacy of SKB500. Patients (pts) with unresectable solid tumors refractory to standard treatment will be enrolled and receive SKB500 at doses ranging from 2 to 18 mg/kg every three weeks (Q3W) until disease progression or unacceptable toxicity. The primary efficacy endpoint was objective response rate (ORR) assessed by investigators per RECIST v1.1. **Results:** As of Dec 23, 2025, 150 pts were treated with SKB500 across all dose levels (2-18 mg/kg). No dose-limiting toxicities (DLT) were observed during dose escalation. Based on preliminary data, the recommended phase 2 dose (RP2D) was established as 12 mg/kg. Among 97 pts treated at 12 mg/kg, the median treatment duration was 6.7 weeks. Treatment-related adverse events (TRAEs) occurred in 70 pts (72.2%), with most frequent (≥20%) being anemia (35.1%), nausea (34.0%), and white blood cell count decreased (24.7%). Grade ≥3 TRAEs occurred in 16 pts (16.5%), with most frequent being anemia, lymphocyte count decreased, pneumonia, and asthenia (each 3.1%). Pneumonitis occurred in 2 pts (2.1%; both grade 1). Both pneumonitis and grade ≥ 3 hematologic toxicities demonstrated low occurrence rates. No TRAEs led to treatment discontinuation or death. Among 55 pts treated at 12 mg/kg who had at least 6 weeks of follow-up (≥2 prior lines: 34.5%; prior platinum: 98.2%; prior IO therapy: 76.4%), the ORR was 54.5% (30/55) and the DCR was 92.7% (51/55). In tumor-specific subgroups, the small cell lung cancer (SCLC) cohort (n = 21) achieved an ORR of 71.4% (15/21) and a DCR of 100% (21/21), while the esophageal squamous cell carcinoma (ESCC) cohort (n = 18) showed an ORR of 55.6% (10/18) and a DCR of 88.9% (16/18). **Conclusions:** SKB500 demonstrated a manageable safety profile and promising antitumor activity in patients with treatment-refractory advanced solid tumors, with notable efficacy in SCLC and ESCC cohorts, supporting further clinical development. Clinical trial information: NCT06736327. Research Sponsor: Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd.

First-in-human study of BG-C9074 (B7-H4–targeting ADC) in advanced solid tumors: Dose escalation and safety expansion. First Author: Binghe Xu, Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China

Background: B7-H4, a transmembrane glycoprotein, has limited expression in normal tissue, but is upregulated in a variety of solid tumors. BG-C9074 is an investigational topoisomerase I inhibitor antibody-drug conjugate (ADC) that targets B7-H4. We present results of monotherapy dose escalation and safety expansion from the ongoing phase 1 study. **Methods:** BG-C9074-101 (NCT06233942) is a first-in-human, multicenter study of BG-C9074 as monotherapy and in combination with other anticancer therapies in patients (pts) with advanced solid tumors. Pts with advanced solid tumors, irrespective of B7-H4 expression, received BG-C9074 IV every 3 weeks in escalating doses from 1 to 9 mg/kg. Endpoints included safety, preliminary antitumor activity (per RECIST v1.1) and pharmacokinetics. **Results:** As of Dec 29, 2025, 123 pts with advanced solid tumors received BG-C9074 monotherapy in phase 1a (ovarian [OC], n = 62; HR+/HER2- breast cancer, n = 28; triple negative breast cancer [TNBC], n = 18; cholangiocarcinoma, n = 11; endometrial, n = 3; squamous non-small cell lung cancer, n = 1). Median (range) prior lines were 4 (0-13). 8 pts experienced DLTs (thrombocytopenia [n = 2, 6.5 mg/kg; n = 1, 7 mg/kg], febrile neutropenia [n = 1, 6.5 mg/kg; n = 1, 7 mg/kg], neutropenic infection [n = 1, 7 mg/kg], fatigue [n = 1, 6 mg/kg], nausea [n = 1, 9 mg/kg], and unexplained death [n = 1, 9 mg/kg]). Treatment-related adverse events (TRAEs) occurred in 113 pts (91.9%); grade (gr) ≥3 in 30.1%. The most common TRAEs were nausea (53.7%; gr ≥3, 4.1%), neutrophil count decreased/neutropenia (44.7%; gr ≥3, 18.7%), and fatigue (37.4%; gr ≥3, 2.4%). Hematologic and gastrointestinal toxicities were manageable with dose modifications and/or supportive care. Among 114 efficacy-evaluable pts, confirmed ORR (cORR) was 28.1% (95% CI: 20.1-37.3), including 2 CRs (1 OC, 6.5 mg/kg, 1 TNBC, 5 mg/kg) and 30 PRs (Table); unconfirmed ORR was 33.3% (24.8-42.8; 3 CRs, 35 PRs). Responses were observed across doses and levels of B7-H4 expression, without consistent association of response with B7-H4 expression across tumor types. Median (range) study follow-up was 6.0 (0.3-17.7) months. ADC and free payload concentrations decreased in a biexponential manner with a half-life of ~7 days for ADC. Exposure for ADC and free payload increased approximately dose proportionally. **Conclusions:** BG-C9074 demonstrates a tolerable safety profile in pts with advanced solid tumors. Encouraging antitumor activity was observed in OC and TNBC. Dose expansion and optimization are ongoing. Clinical trial information: NCT06233942. Research Sponsor: BeOne Medicines Ltd.

3014 **Rapid Oral Abstract Session**

First-in-human trial of BH-30643, a novel macrocyclic, non-covalent, mutant-selective OMNI-EGFR inhibitor, in *EGFR*-mutant (*EGFR*m) NSCLC. First Author: Xiuning Le, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Macrocyclic next-generation tyrosine kinase inhibitors (TKIs) have transformed outcomes in ALK- and ROS1-positive NSCLC; such creatively designed medicines are similarly needed to improve outcomes in EGFR-mutant NSCLC. Using a novel, mutant-selective macrocyclic structure, BH-30643 was designed for super-potency against driver EGFRm, largely sparing wildtype (WT) EGFR, and with unique invulnerability to resistance from C797S with or without T790M. Here we report emerging first-in-human dose-escalation data from the SOLARA trial (NCT06706076). **Methods:** Phase 1 dose escalation used a BOIN design with backfill at potentially efficacious doses. Expansion cohorts targeted populations of interest. Patients (pts) had advanced NSCLC with EGFR and/or HER2 mutations detected on local testing (tissue or plasma). Measurable disease was required; asymptomatic untreated brain metastases (BM) were permitted. Objectives included safety, PK, and RECIST response rate (ORR). Plasma NGS was performed at baseline and on treatment. **Results:** As of 01/05/2026, 72 pts enrolled into dose escalation and backfill across 7 dose levels at a total daily dose of 20mg -160mg, median age 62, 44% Asian, 65% with history of BM, median of 3 prior lines of treatment (range 1-12). EGFR mutations included classical (38 pts), exon20ins (14 pts) and other/atypical (18 pts) or HER2 mutations (2 pts). Plasma exposures at doses of 40mg BID and above achieved > 10x coverage over target EC90 and exceeded exposure levels of most contemporary EGFR TKIs. Common TRAE (> 10%) were WT EGFR-associated, including diarrhea (38%), rash (28%), fatigue (15%), stomatitis (13%), and were predominantly grade 1. Bilirubin elevation was seen in 26 pts (36%) related to off-target UGT1A1 inhibition (Gilbert's-like). Grade 3 TRAE were seen in 15 pts (18%), most commonly bilirubin (8/15); DLTs included bilirubin increase and mucositis, occurring at doses ≥ 60mg BID. No pneumonitis was observed. Responses were observed across diverse EGFRm subsets, including in CNS. Including expansion pts, 28 pts enrolled with C797S on their most recent informative molecular testing (6 with concurrent MET+ or KRAS+), with 23 still on therapy. Of 17 with on-treatment scans, partial responses (confirmed or ongoing) were seen in 10 (59%); ORR was comparable with (50%) or without (66%) T790M. Of 9 pts with baseline C797S detected in ctDNA (3 with T790M), 7 had > 99% reduction of C797S VAF on treatment. **Conclusions:** Leveraging a novel macrocyclic scaffold, BH-30643 is the first TKI monotherapy to demonstrate clinical responses against C797S both with or without T790M. High plasma exposures combined with super-potency, CNS activity, and favorable safety offers potential for deep and durable EGFR inhibition. Enrollment into backfill and expansion cohorts is ongoing to better characterize activity in both TKI-naïve and resistant pts. Clinical trial information: NCT06706076. Research Sponsor: BlossomHill Therapeutics.

Genomically personalized radiation dose de-escalation: A phase II basket radiation study in patients with pathogenic mutations in *ATM*. First Author: Amy Xu, Memorial Sloan Kettering, New York, NY

Background: *ATM* (ataxia-telangiectasia mutated) is a key DNA damage response gene, and pathogenic variants are known to cause a rare hereditary syndrome notable for extreme radiosensitivity. Somatic *ATM* inactivation is associated with markedly improved tumor control following RT. We hypothesized that *ATM*-mutant tumors could achieve effective local control with substantially lower RT doses, reducing normal tissue toxicity. This concept of genomically personalized radiation dose de-escalation was tested in a phase II trial. **Methods:** We conducted a single-arm phase II trial of low-dose RT in patients with metastatic solid tumors harboring pathogenic *ATM* mutations. Eligible patients had radiographic progression suitable for palliation and all patients received 4Gy x 2 fractions- 60% reduced compared to conventional 4Gyx5 palliation-delivered to a target lesion. The primary endpoint was 6-month local failure rate (radiographic progression or re-irradiation) and benchmarked against historical local failure control rates of 82% for 4Gyx5 standard palliation, with pre-specified analysis conducted at this initial dose level. Toxicity was graded by CTCAE criteria. **Results:** Twenty-one patients (across 9 histologies; 3 germline *ATM*, 18 somatic) were enrolled. At 6 months, 12 patients were evaluable; 10 of 12 (83.3%) achieved local control with the 4Gyx2 regimen. Notably, this included a 4.4cm angiosarcoma with a complete response by 6 months- an exceptional outcome with such a low dose. Two patients (16.7%) had local failure by 6 months. Both of these tumors retained ATM protein expression by immunohistochemistry and harbored concurrent pathogenic *TP53* mutations. In contrast, molecular analysis confirmed biallelic *ATM* loss in four patients, including the top three responders. No grade ≥2 toxicities or other significant RT-related side effects were observed. **Conclusions:** *ATM*-mutant tumors were effectively controlled with markedly reduced RT dose (4Gyx2), achieving local control in 83% of lesions at 6 months, comparable to historical response rates with standard palliation (4Gyx5), but with minimal toxicity. Additionally, FACETS analysis showed a stronger correlation with treatment response than germline vs. somatic mutation status, suggesting that FACETS analysis could be more informative in determining eligibility criteria for future clinical trials. These preliminary findings establish *ATM* as a novel biomarker for personalized RT dose de-escalation and compel further investigation into ATM as a therapeutic target. Clinical trial information: NCT05010031. Research Sponsor: Imaging and Radiation Sciences Program (IMRAS); U.S. National Institutes of Health.

A phase 1 study of BGB-B2033 (GPC3 x 4-1BB bispecific antibody) monotherapy in patients with selected advanced or metastatic solid tumors: First disclosure of clinical data. First Author: Hong Jae Chon, CHA Bundang Medical Center, Bundang, South Korea

Background: GPC3 is a tumor-specific antigen that is highly expressed in hepatocellular carcinoma (HCC) and squamous non-small cell lung cancer. 4-1BB is a co-stimulatory receptor on activated T cells that promotes proliferation, survival and cytolysis of T cells. BGB-B2033, a novel, IgG-based GPC3 x 4-1BB bispecific antibody with Fc region engineered to prevent FcγR binding and increase half-life, activates T cells while minimizing systemic toxicity. BGB-B2033 is being studied as monotherapy or in combination in patients (pts) with advanced GPC3-expressing solid tumors in a first-in-human phase 1 trial (NCT06427941). Here we report initial results from the monotherapy dose escalation and safety expansion (part A). **Methods:** In part A, eligible pts with ≥1 prior systemic therapy received ascending dose levels of BGB-B2033. The primary objective was safety. Secondary objectives were preliminary antitumor activity (per investigator-assessed RECIST v1.1), pharmacokinetics, and immunogenicity. Dose escalation followed the Bayesian mTPI-2 design. **Results:** As of December 10, 2025, part A enrolled 61 pts; 60 (98.4%) had HCC and 56 (91.8%) were Asian. Median (range) prior lines of therapy were 2.0 (1-6). The median (range) study follow-up was 3.9 (0.3-14.9) months. Treatment-emergent adverse events (TEAEs) were reported in 63.9% of pts across the 8 dose levels; 27 (44.3%) pts had treatment-related (TR)-TEAEs. Six grade ≥3 TR-TEAEs occurred in 5 (8.2%) pts: alanine aminotransferase (ALT) increased, aspartate aminotransferase increased, blood bilirubin increased, drug eruption, lymphopenia and neutrophil count decreased (1.6% each). One dose-limiting toxicity (ALT increased) resolved after dose reduction. Immune-mediated adverse events (imAEs) were reported in 4 (6.6%) pts; all were grades 1-2. One pt reported a grade 1 infusion-related reaction. In the 59 efficacy-evaluable pts with HCC, confirmed ORR was 20.3% (95% CI: 11.0-32.8), with 12 partial responses; 23 pts had stable disease, 23 had progressive disease, and 1 pt was not evaluable. Ten of the 12 responders had ongoing response at data cutoff. A preliminary dose response was observed; at doses above the predicted target efficacious dose, confirmed ORR was 28.9% (11/38). Serum concentration profiles of BGB-B2033 exhibited target-mediated drug disposition at lower dose levels and decreased in a more biexponential manner at higher dose levels. Soluble 4-1BB, a pharmacodynamic marker, showed a greater increase at higher dose levels. **Conclusions:** BGB-B2033 was generally well tolerated, with limited imAEs in this predominantly 2L+ HCC population. Durable responses were observed in pts with advanced HCC, including pts with prior PD-(L)1-based treatment. Triplet dose escalation with tislelizumab and bevacizumab as well as monotherapy dose expansion are ongoing. Clinical trial information: NCT06427941. Research Sponsor: BeOne Medicines Ltd.

3017 **Rapid Oral Abstract Session**

Luvometinib in adults with neurofibromatosis type 1 and symptomatic, inoperable plexiform neurofibromas: A randomized, double-blind, placebo-controlled, phase 3 trial. First Author: Wenbin Li, Department of Neuro-Oncology, Cancer Center, Beijing Tiantan Hospital, Capital Medical University, Beijing, China

Background: Neurofibromatosis type 1 (NF1) related plexiform neurofibromas (PNs) is associated with significant morbidity, including pain, disfigurement and functional impairment. Surgical treatment for PNs may be limited due to tumor size, location and extent. A randomized, double-blind, placebo-controlled, phase 3 trial (NCT05913037) was conducted to evaluate the efficacy and safety of Luvometinib in adults with inoperable NF1 PN causing significant morbidities. **Methods:** Adults (≥18 yrs) with NF1 and symptomatic, inoperable PNs were randomized in a 2:1 to receive oral Luvometinib (8 mg daily) or placebo in 28-day cycles, stratified by baseline (BL) NRS-11 tumor pain score (≥2 or < 2). An interim analysis was performed at 16 months after the last patient randomization. The primary endpoint was confirmed objective response rate (ORR) by Blinded Independent Review Committe (BIRC) per REiNS criteria. Key secondary endpoints included ORR by the investigator (INV), duration of response (DOR), time to response (TTR) by BIRC and INV, pain severity and safety. **Results:** 167 adults were randomized to receive luvometinib (n = 112) or placebo (n = 55). As of the data cutoff on Aug 19, 2025, the median follow-up was 19.7 months(range: 1.4-25.5). The confirmed ORR assessed by BIRC was 43.8% (95% CI, 34.4-53.4) with luvometinib, compared with 10.9% (95% CI, 4.1-22.3) with placebo ($p < 0.0001$). Luvometinib led to a rapid response (median 3.9 months). The median DOR was 15.1 months (95% CI, 14.8-NE), with a 85.2% rate of DOR ≥12 months with luvometinib. A greater proportion of patients with BL overall tumor pain scores ≥2 experienced a reduction in pain score of at least 2 points with luvometinib compared to placebo (81.0% vs. 53.6%). The most common treatment-emergent adverse events (TEAEs) were folliculitis, increased CPK, mouth ulcer, diarrhea. Serious AEs occurred in 14.3% (luvometinib) versus 7.3% (placebo) of pts. TEAEs led to discontinuation was 1.8% in both groups. **Conclusions:** Our study demonstrated that luvometinib achieved a statistically significant ORR per BIRC compared with placebo, with rapid and durable response, significant reductions in pain severity, and an overall manageable safety profile. These findings suggest that luvometinib may emerge as a new standard treatment for patients with NF1 and symptomatic, inoperable PNs. Clinical trial information: NCT05913037. The efficacy and safety of azvudine (FNC) in phase 1 investigator-initiated study in patients with advanced solid tumors. First Author: Xuemei Zhu, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Azvudine has been approved in China for treatment of AIDS and COVID-19. Serial preclinical studies demonstrated remarkable anti-tumor activity, especially in combination with anti-PD-1 therapy. The mechanistic studies have shown that FNC could significantly reduce myeloid-derived suppressor cells (MDSCs) in the tumor microenvironment. This ongoing phase 1 investigator-initiated study aims to further confirm the nonclinical findings of FNC in cancer patients. **Methods:** Patients with advanced solid tumors who had progressed on standard of care (SoC) therapies were eligible in this single-arm, single-center, open-label study with the primary objective of safety and clinical efficacy. All subjects received the SoC of physician's choice in combination with FNC which was administered orally once daily, with dose escalated across six dose levels: 3mg, 4mg, 5 mg, 6 mg, 7 mg, and 8 mg. **Results:** As of 31 Oct, 2025, 25 subjects were enrolled, including 22 subjects with pMMR/MSS CRC, 3 subjects with NSCLC. All CRC subjects received the triple-combination regimen of FNC, penpulimab, and fruquintinib. Among the CRC subjects, the total ORR was 18.2%, DCR was 72.7%, the mPFS was 4.3 months (95%CI: 3.32,6.31) and the mOS was 7.6 months (95% CI: 5.09,NR). Four subjects achieved the radiographic response (PR), 2 subjects from the 6 mg dose group, and one subject each from the 5 mg and 7 mg dose groups. A subgroup analysis based on liver metastasis status was performed for the 15 subjects enrolled in the 5 mg, 6 mg, and 7 mg dose groups. The ORR for the 7 subjects without liver metastases was 57.1%, the DCR was 100%, and the mean treatment duration was 33.6 weeks. In contrast, among the 8 subjects with liver metastases, the ORR was 0%, the DCR was 87.5%, and with a mean treatment duration of 16.7 weeks. No DLTs occurred in the 16 evaluable subjects during the DLT observation period. TEAEs were reported in 96.0% of patients, with a TRAE incidence of 36.0%. Most TRAEs were Grade 1/2, including hepatic dysfunction (12.0%), γ-GTP increased (8.0%), weight decreased (4.0%), diarrhoea (4.0%), insomnia (4.0%), and ALP increased (4.0%). One Grade ≥3 TRAE weight decreased occurred in the 3 mg group. SAEs were reported in 24.0% (6/25) of subjects, with only one case of weight decreased in 3 mg group considered possibly related to FNC. Two subjects (8.0%) discontinued treatment due to TEAEs, one of which was abnormal liver function, possibly related to FNC. No treatment related deaths, dose interruptions, or dose reductions were reported. **Conclusions:** Overall, the combination of FNC with PD-1 and VEGFR inhibitors was safe and well-tolerated, with encouraging clinical activity in advanced/metastatic pMMR/MSS CRC. Clinical trial information: chiCTR2600116125. Research Sponsor: None.

Discovery from single-cell RNA sequencing profiles of 18 CPTAC glioblastoma patients and validation in bulk profiles of 138 TCGA patients and two human-derived cell lines of a whole-transcriptome predictor of overall survival and drug targets by using quantum mechanics–based AI/ML. First Author: Orly Alter, University of Utah and Prism AI Therapeutics, Inc., Salt Lake City, UT

Background: Single-cell, more than bulk, multi-omic data, are small-cohort, noisy, and high-dimensional, and extremely difficult to model. We have developed artificial intelligence and machine learning (AI/ML) to overcome these challenges [doi: 10.1073/pnas.0530258100]. We have shown that our algorithms are uniquely able to discover accurate, precise, actionable, and mechanistically interpretable predictors, applicable to the general population, from the bulk multi-omes of as few as 19 patients [doi: 10.1158/1538-7445.AM2025-CT227]. We have demonstrated that these predictors of overall survival (OS) and drug targets consistently validate across laboratories and sometimes across indications, in federated and imbalanced studies and over time, and outperform all others where they exist [doi: 10.1063/1.5099268, 10.1200/JCO.2024.42.16_suppl.10043]. Here, we demonstrate our AI/ML in single-cell data. **Methods:** We used our algorithms to derive models from the single-cell RNA sequencing profiles of 18 glioblastoma (GBM) Clinical Proteomic Tumor Analysis Consortium (CPTAC) patients, and tested them in the bulk profiles of 138 patients in the Cancer Genome Atlas (TCGA). CPTAC and TCGA both profiled the core primary tumor of each patient, but CPTAC also sampled the peritumoral brain tissue. The two cohorts are indistinguishable in terms of their gender, age, and OS distributions, but they significantly differ in terms of race. **Results:** A whole-transcriptome model was discovered that is correlated with OS among the 18 CPTAC patients, with a Kaplan-Meier median OS difference of 30 months between the two groups of predictor-stratified patients, and a Cox hazard ratio of 4.6 and a concordance index of 87% (log-rank and Wald P-values $< 5.0\times10$-2). When tested in the TCGA cohort, the model was a similarly significant predictor of OS. In both cohorts, despite the differences in profiling protocols and cohort demographics, the predictor outperformed the best standard-of-care indicator of OS in GBM, i.e., age. Consistent with a previous whole-genome predictor, which was derived from bulk DNA profiles, and validated in a clinical trial [doi: 10.1063/1.5142559], shorter OS was associated with overexpression of such anterior/posterior pattern specification genes as the Notch ligand *DLL3*. We experimentally validated, in two human-derived cell lines, that its putative activator, *METTL2A*, is required for GBM cells' proliferation and viability [doi: 10.1158/1538-7445.AM2025-3686]. **Conclusions:** Our algorithms can discover predictors of patients' OS and drug targets, in real-world small-cohort, noisy, and high-dimensional — single-cell — in addition to bulk multi-omic data, and the predictors experimentally validate. Research Sponsor: NIH/National Cancer Institute (NCI) Physical Sciences in Oncology Project, "Multi-Tensor Decompositions for Personalized Cancer Diagnostics and Prognostics," U01 CA-202144; NSF/American Institute of Mathematics (AIM) Quantum Research Community Project, "AIM Q"; The Musella Foundation in partnership with StacheStrong; Utah Science, Technology, and Research (USTAR) Initiative.

Quantum mechanics-based multi-tensor AI/ML as predictor of patients' overall survival, gene targets, and drug responses from their glioblastoma tumors' whole genomes. First Author: Orly Alter, University of Utah and Prism AI Therapeutics, Inc., Salt Lake City, UT

Background: The drug failure rate has increased to ~95%, despite the growth in targeted therapies. As clinical trials demonstrated, a targeted gene alone does not predict whether patients have longer life expectancy in response to the drug. As studies with model organisms showed, the effect of the drug, and the mechanisms underlying it, depend on the entire multi-ome. But multi-omic data are small-cohort, noisy, and high-dimensional, i.e., extremely difficult to model. **Methods:** We have developed our artificial intelligence and machine learning (AI/ML) to overcome these challenges [doi: 10.1073/pnas.0530258100, 10.1158/1538-7445.AM2025-CT227]. We demonstrated our algorithms in the unsupervised modeling of, e.g., whole genomes of 85 astrocytoma patients. Mechanistic interpretation showed that the modeling blindly removed batch effects, separated normal demographic variations, and discovered a disease-specific genome-wide pattern of DNA copy-number alterations. This pattern was used to derive an actionable predictor of patients' overall survival (OS) and gene targets to sensitize their tumors. We computationally validated both the predictor and the modeling in federated studies of mutually-exclusive sets of 59–251 patients. The modeling repeatedly discovered a representation of the predictor in every study, across astrocytoma grades II, III, and IV, i.e., glioblastoma (GBM), patients. We experimentally validated the predictor in a clinical trial of 79 GBM patients, initially retrospectively, and, in a four-year follow up, also prospectively [doi: 10.1063/1.5142559, 10.1145/3624062.3624078, 10.1200/JCO.2024.42.16_suppl.e14028]. In all the cohorts, the predictor, with 75–95% concordance with OS, was more accurate than all standard-of-care indicators. With 100% reproducibility among Complete Genomics, Illumina, and Ultima whole-genome sequencing, and > 99% when including Affymetrix and Agilent DNA microarrays, the predictor was also the most precise. **Results:** Here, we describe functional genomic experimental validation of both a predicted gene target and the predicted tumors' responses to the targeting. Guide RNAs were designed and a lentiviral CRISPR-Cas9 all-in-one vector was utilized to knock out the modeling-predicted target *METTL2A*. Knockout validation at the protein level was performed using Western blot. Knockout in the patient-derived GBM cell lines U-87 MG and U-118 MG resulted in significantly attenuated cell viability and proliferation. The level of attenuation was significantly different between the cell lines, consistent with their whole genome-based predicted responses. **Conclusions:** Our quantum mechanics-based multi-tensor AI/ML solved the 75-year-old problem of correctly predicting — patients' OS, drug responses, and gene targets — from their GBM tumors' whole genomes. Research Sponsor: NIH/National Cancer Institute (NCI) Physical Sciences in Oncology Project, "Multi-Tensor Decompositions for Personalized Cancer Diagnostics and Prognostics," U01 CA-202144; NSF/American Institute of Mathematics (AIM) Quantum Research Community Project, "AIM Q"; The Musella Foundation in partnership with StacheStrong; Utah Science, Technology, and Research (USTAR) Initiative.

Development and clinical utility of an H&E-based tumor origin prediction model. First Author: Qiyuan Hu, Tempus AI, Inc., Chicago, IL

Background: Tumor of unknown primary origin remains a critical unmet need in oncology, as histologic and anatomic diagnoses are essential for ensuring effective and timely therapies. We previously developed the Tempus Tumor Origin (TO) Laboratory Developed Test (LDT), an RNA sequencing-based machine learning algorithm that discriminates between clinically relevant cancer subtypes. However, RNA-sequencing data is not always available, with a failure rate that can be $>$ 20% in the literature. In this study, we develop and assess the accuracy of a hematoxylin and eosin (H&E)-based machine learning algorithm to predict tumor origin. We also explore combining predictions from H&E and RNA models to improve accuracy further. **Methods:** We curated a cohort of 93,770 H&E whole slide images (WSIs) of tumor biopsies and surgical resections across 67 cancer subtypes from 73,634 patients. The cohort was split into 60/20/20 for training, validation, and testing, stratified by cancer subtypes and clinical covariates. We extracted tile embeddings from WSIs using a foundation model, H-optimus-0, and trained an attention-based multiple instance learning model to predict cancer subtype labels derived from clinically abstracted documents. Using a subset of 54,878 samples that also have predictions from the RNA-based Tempus TO algorithm, we trained and evaluated a multilayer perceptron multimodal model that takes the prediction scores from the H&E model and the RNA model as input. **Results:** On 7,092 test set samples that had both modalities available, the H&E, RNA, and multimodal models achieved top-1 accuracies of 0.85, 0.91, and 0.92 and top-3 accuracies of 0.94, 0.97, and 0.97, respectively. Among subtypes with at least 30 samples in the test set, the multimodal model statistically significantly outperformed the RNA model on five subtypes and underperformed on two. In addition, the H&E model had a top-1 accuracy of 0.77 and a top-3 accuracy of 0.90 on 3,028 samples in the test set that failed RNA sequencing due to quantity insufficient (QNS). Table 1 presents H&E model performance on the RNA QNS samples by diagnosis subtypes. **Conclusions:** We developed a high-performing H&E-based algorithm to predict tumor origin. With shorter turnaround time and wider availability, the H&E model can potentially deliver accurate tumor origin predictions faster and, critically, in cases where RNA-seq is unsuccessful or unavailable. Furthermore, leveraging both H&E and RNA in a multimodal model may improve the performance of future tumor origin algorithms. Research Sponsor: None.

H&E model performance on RNA QNS test set samples in the five most prevalent diagnosis subtypes and other subtypes combined.

Diagnosis subtype	N	Top-1 accuracy (%)	Top-3 accuracy (%)
Lung adenocarcinoma	497	84	94
Prostatic adenocarcinoma	387	92	95
Breast carcinoma	348	83	95
Colorectal adenocarcinoma	327	85	93
Pancreatic adenocarcinoma	272	78	94

Prospective prediction of alisertib-induced Aurora-A kinase resistance mutations in patients with metastatic ER+ breast cancer using an innovative artificial intelligence approach. First Author: Andrew Takchi, Mayo Clinic Rochester, Rochester, MN

Background: Pharmacological blockade of Aurora-A mitotic kinase (AURKA) oncogenic pathway represents a promising therapeutic strategy to inhibit breast cancer plasticity and progression. However, treatment with the selective AURKA inhibitor alisertib is followed by acquired on-target mutations in a subset of patients that are linked to alisertib resistance and tumor progression. Current resistance mechanisms are typically identified retrospectively after therapeutic failure. We evaluated whether Dynaptive, a structure- and evolution-aware artificial intelligence (AI) platform, could prospectively predict treatment-induced AURKA resistance mutations prior to experimental observation. **Methods:** We identified acquired on-target mutations in patients from the alisertib Phase-II clinical trial. These mutations were cross-matched against Dynaptive predictions that had been generated independently of any experimental resistance data. Dynaptive integrates protein conformational ensembles and evolutionary sequence constraints to predict mutational hotspots and assess their functional and drug-binding impact. Identified mutations were evaluated against large-scale population datasets to determine natural occurrence. **Results:** Several AURKA mutations observed in patients that showed resistance to alisertib were prospectively predicted by Dynaptive despite being entirely absent from prior population datasets. These mutations were not observed previously in either healthy or cancer cohorts described in the public domain. Significantly, the most frequently occurring AURKA resistance mutation occurred at a residue ranked second among predicted mutational hotspots and were predicted to reduce alisertib binding affinity by $\geq$10-fold. Across all variants, absence from population datasets and emergence only following treatment support a treatment-induced resistance mechanism. **Conclusions:** A structure-aware AI platform prospectively identified clinically relevant, treatment-induced AURKA resistance mutations prior to experimental detection. These findings demonstrate the feasibility of predictive modeling to anticipate resistance mechanisms and support the development of next-generation AURKA inhibitors optimized to overcome mutations-driven resistance and to improve therapeutic efficacy, safety and durability. Research Sponsor: None.

Light-activated EGFR antibody–drug conjugate: Analysis of selectivity and translational profile for first-in-human evaluation. First Author: Shirlyn Xiao, Shanghai Biophy Biological Pharmaceutical Co., Ltd., Shanghai, China

Background: Conventional antibody–drug conjugates (ADCs) are limited by systemic toxicity and narrow therapeutic windows. Cetuximab-I21-2 is a first-in-class, EGFR-targeted ADC conjugated to a Heloporfin-derived photosensitizer engineered for activation exclusively at the tumor site using red-light irradiation. This approach enables biologically targeted delivery with externally controlled cytotoxic activation, designed to improve the therapeutic index and support safe translation into first-in-human studies. **Methods:** In vitro cytotoxicity was evaluated across EGFR-high, intermediate, and low tumor cell lines (A431, HCC827, Huh7, NCI-N87, MIA-PaCa-2) with or without red-light activation (1–5 J/cm²). Cellular ROS generation, mitochondrial membrane potential disruption, and photodynamic injury were assessed by live-cell imaging. In vivo activity was tested in A431 xenograft-bearing B-NDG mice following a single intravenous dose of Cetuximab-I21-2 (35.3 mg/kg) and localized tumor irradiation at 100 or 200 J. Safety evaluation included body-weight trends and clinical observations. **Results:** Cetuximab-I21-2 showed negligible dark toxicity up to several μg/mL, confirming that the payload remains inactive without illumination. Upon irradiation, the ADC demonstrated potent, energy-dependent cytotoxicity (IC50: 0.05 μg/mL in A431 and 0.14 μg/mL in HCC827 at 5 J/cm²), with reduced effects in EGFR-low models, supporting a target- and activation-dependent mechanism. Illumination triggered rapid singlet-oxygen and ROS production and immediate mitochondrial depolarization. In vivo, Cetuximab-I21-2 achieved irradiation-dependent tumor suppression, reaching 22.2% inhibition at 200 J, and produced histologic photodynamic injury localized to the tumor. Treatment was well tolerated: animals exhibited only transient ($<$10%) weight loss and no systemic toxicity. **Conclusions:** Cetuximab-I21-2 demonstrates a strong translational profile with selective activation, robust preclinical antitumor activity, and a favorable safety margin. The spatial control offered by light activation may enable dose-sparing strategies and reduce systemic adverse events typically associated with ADCs. These findings support advancement toward IND-enabling studies, including optimization of clinical illumination parameters, device–drug integration, and early feasibility planning for first-in-human evaluation in EGFR-expressing solid tumors. Research Sponsor: Shanghai Biophy Biological Pharmaceutical Co., Ltd.

3025 **Poster Session**

First-in-human study of ALK201, a FGFR2b-targeting antibody-drug conjugate (ADC) for patients (pts) with advanced solid tumors. First Author: Dan-yun Ruan, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: ALK201 is a novel ADC comprising of an anti-FGFR2b humanized monoclonal antibody conjugated to topoisomerase I inhibitor Exatecan via a cleavable and highly hydrophilic linker. ALK201 exhibited potent anti-tumor activities in preclinical studies with a tolerable safety profile. Here we report the preliminary results of ALK201 monotherapy for pts with advanced solid tumors from the first-in-human phase I/II trial (NCT06656390). **Methods:** This is an ongoing, multicenter, open-label study being conducted in the US, China, and Australia, which consists of two parts, dose-escalation (Part A) and dose-expansion (Part B). The Part A employs the Bayesian optimal interval (BOIN) with backfilling (BF) design to determine the MTD and recommended doses for Part B. In Part A, pts with advanced solid tumors refractory to standard therapies were treated with ALK201 at 1.5-9.6 mg/kg Q3W. Part B was dose expansion at effective doses identified in Part A. The primary endpoint was safety. Secondary endpoints included efficacy and pharmacokinetics (PK). **Results:** As of December 31, 2025, 38 pts with advanced solid tumors were enrolled in Part A and dosed at 1.5 mg/kg (n=4), 3.0 mg/kg (n=3), 4.8 mg/kg (n=5) ,7.2 mg/kg (n=12), 8.4 mg/kg (n=5) and 9.6 mg/kg (n=9). The median age was 58 years (range 25-74). All pts progressed after receiving a median of 3 prior lines of standard anti-cancer therapy (range 1-8). 28 (73.7%) were Asian and 10 (26.3%) were White. No dose-limiting toxicities (DLTs) have been observed at doses up to 9.6 mg/kg. MTD was not reached. Treatment-related adverse events (TRAEs) occurred in 78.9% pts. The most common TRAEs (incidence $\geq$10%) were nausea (44.7%), anemia (21.1%), vomiting (21.1%), decreased appetite (13.2%), white blood cell count decreased (13.2%), neutrophil count decreased (10.5%), platelet count decreased (10.5%), AST increased (10.5%), hypoalbuminemia (10.5%) and fatigue (10.5%). Grade $\geq$3 TRAEs occurred in 23.7% pts and were exclusively reversible hematologic toxicities. Treatment related ocular adverse events limited to grade 1 in 4 pts (10.5%) with minimal clinical impact. Among 25 pts who were evaluable for response, 6 achieved a partial response (PR), 11 achieved stable disease (SD) in best of response. The objective response rate (ORR) and disease control rate (DCR) were 24% (95% CI: 9.4, 45.1) and 68% (95% CI: 46.5, 85.1), respectively. The ORR and DCR in $\geq$ 7.2mg/kg groups were 35.7% (5/14) and 100% (14/14), respectively. PK analysis showed a dose-dependent ADC and total antibody exposure at doses of 1.5-9.6 mg/kg. ALK201 elimination half-life was approximately 6-11 days. **Conclusions:** ALK201 demonstrated a favorable safety profile in pts with pretreated advanced solid tumors. Promising anti-cancer activity was observed at doses of 7.2 mg/kg and above, warranting further investigation in those effective dose levels. Clinical trial information: NCT06656390. Research Sponsor: Shanghai Allink Biotherapeutics.

Trastuzumab deruxtecan (T-DXd) for pretreated patients in China with HER2 IHC 3+ solid tumors: DESTINY-PanTumor03 Part 1 primary analysis. First Author: Yanqiao Zhang, Department of Gastrointestinal Medical Oncology, Harbin Medical University Cancer Hospital, Harbin, China

Background: Treatment options in China are limited for patients with late-line, HER2-expressing advanced solid tumors. In Part 1 of DESTINY-PanTumor02, T-DXd showed clinically meaningful antitumor activity in HER2-expressing advanced solid tumors, with the greatest benefit observed in HER2 IHC 3+ tumors. Based in part on these findings, T-DXd has been approved in multiple countries worldwide, including the US, as treatment for patients with unresectable or metastatic HER2-positive (IHC 3+) solid tumors who have received prior treatment and/or have no satisfactory alternative therapies. Following the results from DESTINY-PanTumor02, DESTINY-PanTumor03 is evaluating T-DXd in patients in China with HER2-expressing advanced solid tumors. The primary analysis of Part 1 of DESTINY-PanTumor03 is presented here. **Methods:** DESTINY-PanTumor03 is an open-label, Phase 2 study (NCT06271837). Part 1 is evaluating T-DXd (5.4 mg/kg IV Q3W) in patients in China with HER2 IHC 3+ (by central testing), locally advanced, unresectable, or metastatic solid tumors (excluding breast and gastric cancers) after ≥1 prior systemic treatment for advanced disease or without treatment options. The primary endpoint is confirmed objective response rate (ORR) by independent central review (ICR) per RECIST 1.1. Secondary endpoints include ORR by investigator assessment (INV) per RECIST 1.1; duration of response (DOR), disease control rate (DCR), and progression-free survival (PFS) by INV and ICR per RECIST 1.1; overall survival (OS); and safety. **Results:** At primary analysis data cutoff (November 28, 2025), 50 patients with biliary tract (n = 11), colorectal (n = 6), cervical (n = 10), endometrial (n = 7), ovarian (n = 5), non-small cell lung (n = 7), or other cancers (n = 4) had received T-DXd. Median follow-up duration was 9.9 (range 1.1–18.3) months. Median number of prior treatment regimens was 2 (range 1–10). By ICR, ORR (95% CI) was 58.0% (43.2, 71.8), median DOR (95% CI) was 15.4 (12.5, not evaluable [NE]) months, DCR (95% CI) at Week 6 was 88.0% (75.7, 95.5), and median PFS (95% CI) was 15.7 (7.2, NE) months. By INV, ORR (95% CI) was 56.0% (41.3, 70.0). Median OS was not reached. Grade ≥3 drug-related adverse events occurred in 31 (62.0%) patients, and adjudicated drug-related interstitial lung disease / pneumonitis occurred in 4 (8.0%) patients (Grade 2 n = 3 [6.0%], Grade 3 n = 1 [2.0%]). **Conclusions:** T-DXd demonstrated durable and clinically meaningful antitumor activity in pretreated patients in China with HER2 IHC 3+ advanced solid tumors. Safety was generally consistent with the established T-DXd profile. Results from DESTINY-PanTumor03 Part 1 support T-DXd as a tumor-agnostic treatment for patients in China with HER2 IHC 3+ solid tumors. Clinical trial information: NCT06271837. Research Sponsor: AstraZeneca.

Extrapulmonary small cell carcinoma treated with conventional or tumor-targeted topoisomerase I inhibition plus ATR blockade: Clinical outcomes and molecular correlates. First Author: Chirayu Mohindroo, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Extrapulmonary Small Cell Carcinoma (EPSCC) is a rare (0.1–0.4% of all cancers), aggressive neuroendocrine cancer with poor outcomes (Median PFS 2-4 months), no established second-line standard, and limited prospective data. We evaluated ATR inhibition with berzosertib combined with topoisomerase I (TOP1) inhibition with topotecan or sacituzumab govitecan (SG) and explored molecular correlates of response. **Methods:** Given the rare nature of EPSCC, patients were pooled from 3 prospective phase II trials evaluating topotecan or SG with berzosertib (NCT03896503, NCT02487095, NCT04826341) without intent for direct regimen comparison. Eligible patients had platinum-refractory EPSCC and received treatment at recommended phase II doses. Endpoints included efficacy and safety, with exploratory molecular correlates including somatic mutations, copy number alterations, circulating tumor DNA, tumor RNA sequencing, and pharmacogenomic analyses. **Results:** Of the 41 patients enrolled, 34 were evaluable (topotecan+berzosertib, n=20; SG+berzosertib, n=14). ORR based on RECIST was 10% (95% CI, 2.8–30.1) with topotecan+berzosertib and 21.4% (95% CI, 7.6–47.6) with SG+berzosertib; disease-control rates were 45% and 86%, respectively. Durable clinical benefit was observed in subsets of patients, with PFS ≥6.8 months and OS up to 19.7 months in the SG cohort, and OS >18 months in patients treated with topotecan+berzosertib. Patients with prolonged PFS represented multiple primary sites, including bladder, prostate and laryngeal. Grade 3–4 hematologic adverse events were more frequent with topotecan+berzosertib, whereas gastrointestinal toxicity and alopecia were more common with SG+berzosertib; no unexpected safety signals were observed. In the SG cohort, UGT1A1 intermediate and poor metabolizers experienced higher rates (90%) of grade 3–4 toxicities than normal metabolizers (10%). Early ctDNA declines correlated with radiographic response, while rising ctDNA preceded progression; baseline ctDNA correlated with tumor burden (r = 0.83; P = 0.006). Transcriptomic analyses demonstrated enrichment of E2F-driven and neuroendocrine lineage programs in responders (NES = 1.64–1.67; P < 0.001). **Conclusions:** In relapsed or refractory EPSCC targeting tumor replication stress through combined ATR and TOP1 pathway inhibition yielded clinically meaningful activity. Tumor-targeted TOP1 delivery with SG plus berzosertib achieved disease-control rate and a manageable safety profile. UGT1A1 phenotype was associated with toxicity in the SG cohort, supporting the relevance of pharmacogenomic-guided risk stratification. Correlative analyses identified E2F-driven transcriptional programs, neuroendocrine lineage signatures and early ctDNA suppression as promising biomarkers for future trials. Clinical trial information: NCT03896503, NCT02487095, NCT04826341. Research Sponsor: None.

First-in-human phase I/II study of MRG006A, a first-in-class Glypican-3 (GPC3)–targeted antibody-drug conjugate (ADC), in patients (pts) with advanced hepatocellular carcinoma (HCC). First Author: Hong Zhao, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, Beijing, China

Background: Pts with advanced HCC face limited treatment options beyond immunotherapy and anti-angiogenic agents. GPC3, a surface antigen overexpressed in HCC and associated with poor prognosis, represents a promising therapeutic target due to its tumor-specific expression. MRG006A, a potential first-in-class GPC3-targeted ADC, demonstrated potent pre-clinical anti-tumor activity. Here we report the preliminary safety and efficacy of MRG006A in advanced HCC with intermediate/high GPC3 expression from a phase I/II trial. **Methods:** MRG006A-001 (NCT07093970) is an ongoing first-in-human, open-label, multicenter phase I/II study. The phase I study comprises dose escalation (Ia) and dose optimization/expansion (Ib) stages. The dose-escalation employed an accelerated titration plus 3+3 design. Eligible pts who had failed standard treatment received MRG006A intravenously at 1.6-6.4 mg/kg every three weeks (Q3W). GPC3 expression was only required for dose expansion cohorts. The primary endpoints were safety and tolerability. Secondary endpoints included objective response rate (ORR), disease control rate (DCR), duration of response (DOR), progression-free survival (PFS), clinical benefit rate (CBR), etc. **Results:** As of Dec 19, 2025, the maximum administered dose was established as 6.4 mg/kg Q3W, with ≥ G3 treatment-related adverse event (TRAE) of platelet count decreased reported in all six pts at this dose level and dose-limiting toxicity (G4 platelet count decreased) observed in one patient. During dose escalation, tumor response was observed at 3.2 mg/kg and 4.8 mg/kg. Accordingly, dose optimization in phase Ib proceeded with three levels (3.2, 4.0, and 4.8 mg/kg Q3W). Twenty-six HCC pts with intermediate or high GPC3 expression were enrolled across three cohorts; 61.5% had BCLC stage C disease; median 2 (range 1-4) prior lines of therapy, and 25 (96.2%) had received immune checkpoint inhibitors and anti-angiogenic agents. Among 25 efficacy evaluable pts, ORR, DCR and CBR were 23.1%, 68.0% and 32.0%, respectively. In pts with high GPC3 expression (n=12), ORR, DCR and CBR increased to 33.3%, 75.0% and 50.0%, respectively; median PFS and DOR were 7.0 and 4.2 months (median follow-up 5.7 months). Most pts (24 [92.3%]) experienced TRAE of any Grade. TRAEs of ≥ G3 were reported in 11 (42.3%) pts . The most common TRAEs were platelet count decreased (88.5%), blood bilirubin increased (50.0%), AST increased (46.2%), white blood cell count decreased (38.5%), and nausea (30.8%). No treatment-related permanent discontinuations or deaths occurred. **Conclusions:** MRG006A demonstrated manageable safety and promising antitumor activity in heavily pretreated pts with GPC3-expressing advanced HCC. Our findings support the therapeutic potential of GPC3-directed ADC and merits further clinical investigations. Clinical trial information: NCT07093970. Research Sponsor: None.

Consideration of adjusted ideal body weight dosing in BG-C9074 (B7-H4–targeting ADC) from pharmacokinetics, efficacy, and safety perspectives. First Author: Hugh Giovinazzo, BeOne Medicines Ltd, San Carlos, CA

Background: B7-H4 is a transmembrane glycoprotein that is upregulated in a variety of solid tumors. BG-C9074 is an investigational topoisomerase I inhibitor antibody-drug conjugate (ADC) that targets B7-H4. We present results of the pharmacokinetic (PK) and exposure-response (ER) analyses supporting the implementation of adjusted ideal body weight (AiBW)-based dosing in the ongoing phase 1 study. **Methods:** BG-C9074-101 (NCT06233942) is a first-in-human, multicenter study designed to assess BG-C9074 as monotherapy and in combination with other anticancer therapies in patients (pts) with advanced solid tumors. Total body weight (TBW) and AiBW-based dosing were evaluated at 1-7 mg/kg and 6.5-9 mg/kg, respectively, administered intravenously every 3 weeks. PK samples were collected to measure serum ADC and plasma free P1021 payload analytes at Cycle 1 and steady state (Cycle 5). A population PK model, incorporating both ADC and payload, was developed and used to evaluate safety and efficacy ER relationships. **Results:** As of October 30, 2025, PK, safety, and efficacy data were available for 107 pts with advanced solid tumors. TBW dosing of BG-C9074 led to a maximum tolerated dose < 7 mg/kg. The ADC and free payload exposures increased with BW for TBW dosing, while ADC clearance moderately increased with BW leading to higher exposure in high BW patients (Table 1). Higher ADC exposure was associated with an increased incidence of Grade ≥3 treatment-related adverse events (TRAEs), predominantly neutropenia. Early dose modifications and use of granulocyte colony-stimulating factor were more frequent at higher doses and exposures. Increased and sustained tumor shrinkage observed in pts with ovarian cancer (OC) with higher ADC exposure. AiBW enabled a higher tolerable dose at 8 mg/kg, by normalizing ADC and payload exposure across all bodyweight ranges. **Conclusions:** AiBW dosing effectively reduced PK variability compared with TBW dosing, providing more consistent exposure across BW. Higher ADC exposure was associated with increased efficacy, but also with a higher incidence of manageable TRAEs. AiBW optimizes the risk-benefit profiles across BW. Clinical trial information: NCT06233942. Research Sponsor: BeOne Medicines Ltd.

Phase I study of BL-M05D1, a novel Claudin18.2-directed antibody-drug conjugate (ADC), in patients with locally advanced or metastatic Claudin18.2–expressing solid tumors. First Author: Siyuan Cheng, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Department of Gastrointestinal Oncology, Peking University Cancer Hospital & Institute, Beijing, China

Background: BL-M05D1 is a novel Claudin18.2-directed ADC with a potent topoisomerase I inhibitor Ed-04. Results for safety and efficacy data from a phase I study on BL-M05D1 in patients (pts) with locally advanced or metastatic (LA/M) Claudin18.2-expressing solid tumors are presented. **Methods:** Pts who had LA/M solid tumors enrolled in dose escalation and dose expansion phase, and treated with BL-M05D1 at 0.66, 2.0, 3.0, 4.0 or 5.0mg/kg on Day 1 every 3 weeks (D1 Q3W). Gastric cancer/gastroesophageal junction cancer (GC/GEJ), biliary tract cancer (BTC), and pancreatic cancer (PanC) patients with Claudin18.2-expressing enrolled in dose expansion phase were treated at 2.0, 3.0 or 4.0mg/kg D1 Q3W. **Results:** As of Nov 30, 2025, a total of 245 pts were enrolled (87 GC/GEJ, 53 BTC, 104 PanC) and 1 other). The most frequent grade≥3 TRAEs were all hematological, including thrombocytopenia (33.9%), neutropenia (32.7%), leukopenia (31.8%) and anemia (14.3%); non-hematologic TRAEs were relatively low. One pt at 5.0mg/kg group experienced grade 3 febrile neutropenia as a DLT. No treatment-related deaths or ILD were reported. In PanC, BL-M05D1 has demonstrated a promising efficacy with an ORR of 35.7% and mPFS of 5.6 mo at 4.0mg/kg in CLDN18.2-positive pts; in the second line pts, ORR was 50.0% with a mPFS of 5.7 mo. Furthermore, BL-M05D1 has shown promising efficacies in CLDN18.2-positive GC and BTC with an ORR of 39.2% and 37.9%, and mPFS of 5.4 mo and 5.9 mo, respectively, at 4.0mg/kg. Efficacy results are summarized below. **Conclusions:** BL-M05D1 has demonstrated a promising antitumor activity with a tolerable safety profile in pts with pretreated Claudin18.2-positive PanC, GC, and BTC. 4.0mg/kg D1 Q3W was chosen as RP2D. The data support further development of BL-M05D1 in Claudin18.2-positive PanC, GC, and BTC. Phase III studies are in preparation. Clinical trial information: NCT06349811. Research Sponsor: Baili-Bio (Chengdu) Pharmaceutical Co., Ltd.

HER2-independent antitumor and pharmacodynamic responses to trastuzumab deruxtecan in patients with advanced solid tumors. First Author: Sarah Shin, Developmental Therapeutics Clinic/Early Clinical Trials Development Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Trastuzumab deruxtecan (T-DXd) is a HER2-directed antibody conjugated to topoisomerase 1 inhibitor, deruxtecan, payload that is an effective treatment strategy across several tumor types and various HER2 expressions. The relative contributions of each of the underlying mechanisms driving the broad clinical activity require further elucidation for the ongoing rational development of this promising agent. To this end, our pilot study (NCT04294628) evaluates the pharmacodynamics (PD) of T-DXd in patients (pts) with solid tumors displaying a variety of HER2 expression levels. **Methods:** This multicenter pilot study enrolled pts with HER2-expressing advanced solid tumors as defined by HER2 immunohistochemistry (IHC) score of 1+ or greater or *ERBB2* amplifications (amp) or mutations (mut). Baseline HER2 expression was evaluated by Ventana PATHWAY immunohistochemical (IHC) analysis. T-DXd was administered at 5.4 mg/kg intravenously once every 3 weeks, in 21-day cycles (C), with mandatory tumor biopsies collected at baseline, post-dose C1, and pre-dose C3. Blood samples for biomarker analyses were collected throughout the study. PD biomarkers for topoisomerase 1 (TOP1) target engagement, consequent DNA damage repair (DDR), and tumor immune microenvironment changes were analyzed. Overall response was also evaluated. **Results:** Sixty-one pts received T-DXd. Eligibility HER2 (eHER2) status was determined from pt records: 21 IHC 1+, 22 IHC 2+, 7 IHC 3+, 8 *ERBB2* amp, 3 *ERBB2* mut. Of the 41 pts with baseline biopsies centrally assessed for HER2 (bHER2) by IHC, 13 had bHER2 scores discordant with eHER2, including 8 patients who were eHER2 1-2+ but were bHER2 null. No new safety signals were observed. One pt had a complete response (cervical, bHER2 3+), 14 pts had confirmed partial responses (PR), including 3 who were bHER2 null (2 ovarian, 1 uterine), and 5 pts had unconfirmed PR (uPR). Of the 21 paired biopsies assessable for PD response, 15 demonstrated TOP1 target modulation and 14 of those 15 also demonstrated DDR induction. Substantial tumor infiltration and activation of CD8+ T cells at baseline and/or following T-DXd administration occurred in several patients and were particularly prevalent in those with response. In the one responding patient where lesion-specific analyses were possible, we observed significant diameter reduction (3.9 cm to 1.9 cm) and PD responses in a bHER2 null lesion. **Conclusions:** Clinical responses and target modulation were observed in pts irrespective of bHER2 expression. Lesion-specific analyses provide evidence of antitumor activity and target engagement even in a bHER2-null lesion. Genomic analyses to identify additional molecular determinants of response or resistance to T-DXd are ongoing. This project was funded in part by the National Cancer Institute, National Institutes of Health, under Contract No. 75N91019D00024. Clinical trial information: NCT04294628. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health.

3032 Poster Session

First-in-human phase 1 study of TQB6411, an EGFR/c-Met bispecific antibody-drug conjugate (ADC), in patients with advanced solid tumors. First Author: Shengxiang Ren, Shanghai Pulmonary Hospital, School of Medicine, Tongji University, Shanghai, Shanghai, China

Background: EGFR and c-Met overexpression are common across various solid tumors. TQB6411 is a novel ADC binding to both EGFR and c-Met with a valency of 1:2 to enhance the affinity to c-Met. Here we report the preliminary results of this first-in-human phase 1 study of TQB6411(NCT07043751). **Methods:** Patients (pts) with advanced malignant tumor who had failed or were intolerant to standard treatment were eligible. TQB6411 was administered intravenously once every 3 weeks. An accelerated titration design was used for the initial dose level (0.8 mg/kg), followed by a conventional 3+3 dose escalation design for the remaining dose levels. The primary endpoints were dose-limiting toxicity (DLT), recommended phase II dose and safety. **Results:** As of December 31, 2025, 26 pts were enrolled and received research treatment (median age [range], 60[33–75] years; 46.2% female). The most common diagnosis was non-small cell lung cancer (NSCLC, 21 pts), followed by esophageal cancer (EC, 3 pts) and colorectal cancer (CC, 2 pts). All pts had received at least one previous line of systemic treatment. Dose group assignments were as follows: 1 in 0.8mg/kg, 3 in 2.4mg/kg, 13 in 4mg/kg, 6 in 5.3mg/kg, and 3 in 6.6mg/kg. By the data cutoff date of January 9, 2026, the dose had been escalated to 6.6mg/kg, with no DLT occurring. The median treatment duration was 3 cycles (rang:1-9). In 22 pts who were followed up for at least 21 days, 19 (86.4%) experienced at least 1 treatment-related adverse event (TRAE). The most common TRAEs included asthenia (54.5%), infusion reaction (50.0%, decreasing to 38.9% in the ≥4 mg/kg dose group after prophylaxis modification), myalgia (27.3%), alopecia (22.7%), and neutrophil count decreased (22.7%). No interstitial lung disease occurred. Only 4 cases of grade 3 AEs (two of neutrophil count decreased, one of allergic shock, one of white blood cell count decreased) were observed in 3 pts and were all attributed to TQB6411. No ≥ grade 4 AEs occurred. In the ≥4 mg/kg dose group, 8 pts received at least one imaging assessment, 4 achieved a partial response (PR), giving an objective response rate of 50.0%. The disease control rate was 100%. The details of efficacy results are shown in the table below. **Conclusions:** In this ongoing phase 1 study. TQB6411 showed an impressive safety profile, with a lower incidence of higher-grade TRAEs (especially lower haematological toxicities), and encouraging efficacy, with tumor responses could be observed even in the relatively lower dose group. Clinical trial information: NCT07043751. Research Sponsor: None.

Clinical outcomes in phase 1 study of EBC-129, a first-in-class, anti–N256-glycosylated CEACAM5 and CEACAM6 antibody-drug conjugate (ADC), in patients with gastroesophageal adenocarcinomas. First Author: Wei-Peng Yong, National University Cancer Institute Singapore (NCIS), Singapore, Singapore

Background: Gastro-oesophageal adenocarcinoma (GEA) is an aggressive malignancy with limited treatment options. EBC-129 is a first in class MMAE-linked ADC against both, N256-glycosylated CEACAM5 and 6. Previously reported dose escalation data identified 1.8 and 2.2 mg/kg Q3W as the RP2Ds. Here we report pooled safety and efficacy data of GEA patients enrolled in dose escalation (DEs) and expansion (DEx) cohorts of the Phase 1 study (NCT05701527). **Methods:** This study consisted of DEs and DEx cohorts. Previously treated patients with histologically confirmed, locally advanced or metastatic GEA with centrally confirmed immunohistochemistry (IHC) positivity at ≥20% at 2^+ and/or 3^+ on archival samples were enrolled. Objectives were to evaluate safety, efficacy, PK of EBC-129, administered every 3 weeks. **Results:** A total of 21 GEA patients were enrolled (4 in DEs and 17 in DEx). Pre-screening data shows that 57% and 77% are positive in IHC at cut-offs of ≥20% at $2/3^+$ and ≥1% at 3^+, respectively. Patients received 1.2 (n=1), 1.8 (n=9), 2.0 (n=1) or 2.2 (n=10) mg/kg EBC-129 Q3W. 81% were male; mean age 59.0 years; median 3 (range 1-9) lines of previous treatments with 62% prior taxane treated. At data cut-off (9th Jan 2026), 3 patients are continuing treatment, 12 patients had radiological progression, 3 had clinical progression, and 3 patients withdrew from treatment. Among the 17 evaluable patients, the ORR, DCR and median PFS are outlined in the table below. ORR of 50% was seen in patients with an IHC ≥50%. 65% of patients had any tumour shrinkage overall. Infusion related reactions (IRRs) were seen in 43% of patients most being Grade 1/2 and resolved or reduced with premedication; except for 1 patient who had Grade 3 IRR. The other ≥3 Grade TRAEs (CTCAE v5) included neutropenia (52.4%), anaemia (14.3%), WBC count decreased (9.5%), diarrhoea (9.5%); and amylase increase, vomiting, anorexia, nausea in 1 patient each (4.8%). 4 patients (19.0%) experienced peripheral neuropathy (3 grade 1, 1 grade 2). Other than the 1 patient with Grade 3 IRR, no other drug-related discontinuations occurred in this cohort. Higher antigen expression levels correlated with better response. **Conclusions:** EBC-129 shows promising clinical activity in heavily treated GEA patients with a manageable tolerability profile. Further evaluation in 2L GEA is planned. Clinical trial information: NCT05701527. Research Sponsor: National Research Foundation.

Efficacy results from EBC-129-01, GEA cohort.

Dose	IHC status*	ORR^	DCR	mPFS (wks)
1.8 mg/kg	≥20% (n=7)	28.5%	85.7%	18.1
1.8 mg/kg	≥50% (n=4)	50%	100%	29.2
2.2 mg/kg	≥20% (n=8)	25.0%	75.0%	10.1

Real-world effectiveness of sacituzumab govitecan (SG) versus trastuzumab deruxtecan (T-DXd) in HER2-negative (HER2-) metastatic breast cancer (MBC) in China: A propensity-score–matched study. First Author: Biyun Wang, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: SG and T-DXd are both antibody-drug conjugates (ADC) approved in China for HER2- MBC patients. However, direct real-world comparisons between these two therapies in HER2- MBC patients in China remain limited. This study aimed to evaluate and compare clinical outcomes of SG and T-DXd in Chinese patients with HER2- MBC in real-world practice. **Methods:** This retrospective study included 306 HER2- MBC patients, with 151 treated with SG and 155 treated with T-DXd. Separate propensity score matching (PSM) was performed for the triple-negative (TN) and hormone receptor-positive (HoR+) cohorts, respectively. Matching variables for both cohorts included age, HER2 expression, prior ADC use, number and site of metastases (liver, brain), and prior lines of therapy. For TN cohort only, DFI, prior taxane and PD-1/PD-L1 inhibitor use were additionally matched (caliper = 0.1). Clinical outcomes included real-world progression-free survival (rwPFS), overall survival (OS), objective response rate (ORR) and disease control rate (DCR). **Results:** Median follow-up was 13.4 mo (SG-TN), 12.0 mo (SG-HoR+), 12.4 mo (T-DXd-TN), and 12.0 mo (T-DXd-HoR+). After PSM, 33 TN patients and 28 HoR+HER2- patients were matched in each treatment group. Baseline clinical characteristics were well-balanced. In TN patients, rwPFS was comparable between SG and T-DXd (5.0 vs 5.7 mo, HR=0.63, *P*=0.138). The comparable effectiveness of SG and T-DXd was also observed in both HER2-null (*P*=0.498) and HER2-low (*P*=0.250) subgroup. Meanwhile, SG showed a trend toward improved rwOS (NR vs 13.1 mo, HR=1.75, *P*=0.216). However, T-DXd demonstrated significantly higher ORR (18.2% vs 45.5%, *P*=0.017) and DCR (45.5% vs 75.8%, *P*=0.012) compared to SG. In HoR+HER2- patients, T-DXd showed significantly longer rwPFS compared to SG (9.8 vs 5.5 mo, HR=0.41, *P*=0.010), especially among those with HER2-low disease (8.4 vs 5.3 mo, HR=0.36, *P*=0.007); OS data were immature. ORR (14.3% vs 39.3%, *P*=0.035) and DCR (42.9% vs 85.7%, *P*<0.001) favored T-DXd, as well. Subgroup analyses indicated that T-DXd in those with DFI >12 months prolonged rwPFS than SG (10.2 vs 3.5 mo, HR=0.46, *P*=0.036). In HoR+ patients, the median rwPFS was significantly longer in T-DXd group than SG group in the majority of subgroups. **Conclusions:** In this real-world PSM analysis, T-DXd showed improved rwPFS compared with SG in HoR+HER2- MBC patients, while both regimens had generally comparable effectiveness in TN patients. These findings suggest that treatment selection may be influenced by hormone receptor status and the duration of DFI. Further prospective studies are warranted to validate these observations. 3035 **Poster Session**

BC3195, a novel ADC targeting cadherin-3 (CDH3): Preliminary results of a phase I study in patients with advanced solid malignancies (study BC3195-102). First Author: Madison Conces, Department of Oncology, University Hospitals Seidman Cancer Center, Case Western Reserve University, Cleveland, OH

Background: Cadherin-3 (CDH3), a calcium-dependent adhesion glycoprotein, is overexpressed on lung, breast, ovarian, colorectal, pancreatic, head-neck and other malignancies, but expression on nonmalignant tissue is negligible. CDH3 is essential for cancer cell proliferative signaling and is associated with aggressiveness, invasiveness and poor prognosis. BC3195 is an antibody-drug conjugate (ADC) comprised of an antibody targeting CDH3, a cleavable linker and a monomethyl auristatin E (MMAE) payload. **Methods:** Two phase Ia/Ib studies of BC3195, whose objectives are to evaluate the safety, pharmacokinetics (PK) and preliminary antitumor activity of the ADC, are enrolling patients (pts) with advanced solid malignancies in the US (BC3195-102) and China (BC3195-101). In both studies, BC3195 is administered as a 1-hour (h) IV infusion every 3 weeks. In BC3195-102, dose escalation uses a BOIN design with pre-selected dose levels (DLs) of 1.8 and 2.4 mg/kg and an algorithm to explore lower or intermediate DLs based on safety. **Results:** As of data cut-off (Dec 30, 2025), 16 pts have been enrolled at DLs of 1.2 (3 pts), 1.5 (3 pts), 1.8 (9 pts), and 2.4 mg/kg (1 pt). Fourteen (87.5%) pts had received ≥3 prior treatment. Fatigue (81.3%) and stomatitis (62.5%) were the main adverse events (AEs). Three pts (18.8%) had Grade ≥3 AEs, two of which were Grade 3 stomatitis in the first week post-treatment of Cycle 1 at the 1.8 mg/kg DL of Cohort 1. The dose of BC3195 was subsequently de-escalated to 1.2 mg/kg and then re-escalated to 2.4 mg/kg along with preventative measures, which included ice chip mouth rinses, dexamethasone mouthwash, and B vitamins in the peri-treatment period, and topical steroids for any skin rash. There was no further stomatitis of Grade 3 severity after implementation of these measures; 1 pt had a Grade 3 rash in Cycle 2 at 1.5 mg/kg that responded rapidly to oral steroids. Neither ocular nor neurotoxicity have been noted. Of 16 pts evaluable for tumor response (RECISTv1.1), 3 partial responses occurred in heavily pretreated pts with HER+ breast cancer, prostate cancer, and fibrosarcoma, all of whom were treated at the 1.8 mg/kg DL. Preliminary PK results (1.2-1.8 mg/kg) include med T_{max} values of 1 h for both ADC and total antibody (TA), whereas med T_{max} values for free MMAE range from 65 to 89 h. At 1.8 mg/kg, mean $t_{1/2}$ values are 58 h, 92 h, and 95 h for the ADC, TA and MMAE, respectively. ADC exposure has been highest at 1.8 mg/kg, with mean C_{max} and AUC_{last} values of 31.8 μg/mL and 1297 μg*h/mL, respectively. **Conclusions:** BC3195 has a manageable safety profile, favorable PK characteristics and demonstrated preliminary antitumor activity in several types of heavily pretreated advanced solid malignancies. Based on shared safety data, enrolment in both BC3195-102 (US) and BC3195-101 (China), which is in dose expansion, is converging on the 2.1 mg/kg DL (NCT06548672). Clinical trial information: NCT06548672. Research Sponsor: Biocity Biopharmaceutics Co. Ltd.

3036 **Poster Session**

XNW27011, a Claudin 18.2(CLDN18.2) targeted antibody-drug conjugate (ADC), in patients with CLDN18.2-positive gastric/gastroesophageal junction adenocarcinoma (G/GEJA): A phase 2 study. First Author: Linlin Wang, Affiliated Hospital of Shandong First Medical University, Jinan, China

Background: The prognosis of G/GEJA remains poor, especially in late line patients (pts). mPFS for G/GEJA pts who received ≥ 2 prior lines of standard therapy is 1.6 - 2.6 months (mos). XNW27011 is a novel antibody-drug conjugate (ADC) targeting CLDN18.2, a promising therapeutic target that is aberrantly expressed in patients with G/GEJA. **Methods:** This phase 2 study aims to evaluate the efficacy and safety of XNW27011. Adult pt with advanced solid tumors who has failed standard therapy or is intolerable to available standard therapy/without available standard therapy, and with CLDN18.2 expression in ≥5% tumor cells (TC) with IHC staining ≥2+ (IHC≥2+, TC≥5%, EPR19202) were enrolled, including G/GEJA pts. All patients had measurable disease (RECIST v1.1) and ECOG 0-1. Patients received XNW27011 at 2.4-4.8 mg/kg Q3W. Endpoints included ORR for efficacy, TRAE events for safety and PK parameters. **Results:** As of Dec 29, 2025, a total of 86 eligible G/GEJA pts were enrolled at 2.4-4.8 mg/kg. IHC≥2+, TC≥20% was chosen as the CLDN18.2 expression criteria for further development of XNW27011. Here, we report the results in G/GEJA pts with CLDN18.2 expression of IHC≥2+, TC≥20%. Safety: 71 enrolled pts had CLDN18.2 expression of IHC≥2+, TC≥20%. The median age was 57.0 years, 87.3% of the pts had received ≥2 lines of systemic therapy, 85.9% of the pts had received immune checkpoint inhibitors. The common TRAEs (≥20%) included anemia, nausea, white blood cell count decreased, decreased appetite, neutrophil count decreased, vomiting, weight loss, hypoalbuminemia, asthenia, platelet count decreased, lymphocyte count decreased and hypokalemia. Efficacy: At 3.0 mg/kg, 26 patients were evaluable for efficacy, with 23 and 3 pts had received ≥2 and 1 prior lines of systemic therapy, respectively. The median follow-up(mFU) was 11.3 mos, cORR and cDCR were 65.4% and 84.6%, respectively. mPFS was 5.7 mos and mOS was 11.7 mos. Among the 23 pts who had ≥2 prior lines of therapy, the mPFS was 6.8 mos and mOS was 11.9 mos, with the mFU of 11.5 mos. Notably, one patient previously treated with CLDN18.2-targeted therapy still demonstrated durable clinical benefit, with PFS of 11.3 mos and still remains on treatment as of data cutoff date. Pharmacokinetics: At doses from 0.6 - 6.0 mg/kg in pts with solid tumors including G/GEJA, XNW27011 exposure (C_{max} and $AUC_{0-\infty}$) increased in an approximately dose proportional manner with a half-life of 5~7 days. Across all dose levels, circulating blood payload concentrations were low with 3.3% ADA positive rate. **Conclusions:** XNW27011 demonstrated promising anti-tumor activity and a manageable safety profile in CLDN18.2-positive G/GEJA. A pivotal phase 3 study evaluating XNW27011 as a ≥3 line therapy in G/GEJA pts is currently ongoing. Clinical trial information: NCT06792435. Research Sponsor: Evopoint Biosciences Co., Ltd.

3037 **Poster Session**

First-in-human study of DM002, an anti-MUC1/HER3 bispecific antibody-drug conjugate, in patients with advanced solid tumors. First Author: Xian Jun Yu, Fudan University Shanghai Cancer Center, Shanghai, China

Background: DM002 is a bispecific ADC (BsADC) conjugated to BLD1102, a linker/payload system composed of a linker and a DNA topoisomerase I inhibitor (BCPT02), targeting MUC1 and HER3 with an average DAR value of 8. MUC1 and HER3 are highly co-expressed in several types of solid tumors, for which DM002 has demonstrated robust anti-tumor activity in PDX/CDX models. **Methods:** This is a First-in-human dose-escalation study (NCT06751329). Patients (pts) with advanced solid tumors received DM002 by IV administration from 1 to 6.0 mg/kg Q3W. The classical "3+3" design was utilized to evaluate safety, tolerability and preliminary efficacy. Tumor response was evaluated by the Investigators based on RECIST v 1.1. A Safety Monitoring Committee (SMC) was established to determine the dose levels, dose regimen, and the maximum tolerated dose (MTD)/ recommended dose for expansion (RDE). **Results:** As of 28 Dec 2025, a total of 29 pts from China, United states of America and Australia were enrolled and received ≥1 dose of DM002 across 5 dose cohorts. Median age was 61 years (range 45-80). Baseline ECOG scores were 0 (n=8), 1 (n=21) with all pts progressed after an average of 2.5 (range 1-5) prior lines of available standard therapy. There were three dose-limiting toxicities observed in 2 patients at 6.0 mg/kg. The MTD is 4.5mg/kg. Nineteen pts (65.5%) experienced treatment-related adverse events (TRAEs), mainly manifested as hematological toxicity and gastrointestinal reactions. the most common TRAEs (≥15%) including: nausea (37.9%), neutropenia (37.9%), thrombocytopenia (34.5%), anemia (31%), vomiting (27.6%), leukopenia (20.7%), hyponatremia (20.7%), diarrhea (17.2%), alanine aminotransferase increased (17.2%), hypoalbuminemia (17.2%). Most TRAEs were Grade 1-2 and Grade ≥3 TRAEs reported in 12 pts (9 neutropenia, 5 leukopenia, 4 thrombocytopenia, 3 anemia, 2 lymphocytopenia, hyponatremia and febrile neutropenia, 1 aspartate aminotransferase increased, blood bilirubin increased, monocyte count decreased, myelosuppression, hypocalcemia, malaise and infection). No ILD was observed. Among 15 pts having imaging tumor assessment by RECIST v1.1, there were 3 PRs, including 1 pt with prostate cancer and 1pt with ovarian cancer at 3.0 mg/kg, and 1 pt with pancreatic cancer at 4.5 mg/kg, and 8 pts with stable disease (SD). In the 3.0/4.5/6.0 mg/kg dose groups, a total of 8 pancreatic pts underwent imaging tumor assessment, with 1 pt achieving PR, and 5 pts achieving stable disease (SD). **Conclusions:** DM002 is safe and tolerable up to 4.5 mg/kg dose level. In pancreatic cancer, prostate cancer and ovarian cancer, DM002 has demonstrated an encouraging efficacy with a manageable safety profile. The putative RDEs are 3.0 and 3.5 mg/kg which will be further evaluated in phase II trials. Clinical trial information: NCT06751329. Research Sponsor: None.

3038 Poster Session

A phase 1b/2 study of JK06, a 5T4-targeted antibody-drug conjugate (ADC), in patients with unresectable locally advanced or metastatic cancer. First Author: Omar Saavedra, New Experimental Therapeutics (NEXT), Hospital Universitario Quirónsalud, Barcelona, Spain

Background: 5T4, a Type I transmembrane glycoprotein, is over expressed in a broad spectrum of solid tumors. It modulates the CXCR4 & WNT signaling pathways contributing to epithelial to mesenchymal transition contributing to metastatic progression & correlates with poor clinical outcomes among a range of cancers, such as NSCLC, CRC & ovarian. JK06 is a tetravalent, biparatopic DAR2 MMAE ADC targeting 5T4, providing picomolar affinity & enhanced internalization to compensate for generally lower 5T4 expression levels & poor intrinsic internalization kinetics. **Methods:** Pts with advanced relapsed/refractory solid tumors, unselected for 5T4 expression, receive IV JK06 monotherapy once every 3 wks. Dose escalation has been completed, and the study is currently enrolling multiple tumor-specific cohort expansions with randomization across two doses of JK06 to identify an RP2D in NSCLC & breast cancer. Fresh & archival tumor biopsies are being collected for retrospective correlation of 5T4 expression to efficacy & safety. Responses are assessed every 9 wks per RECIST v1.1. Exploratory evaluations of changes in quality of life after JK06 treatment are included in cohort expansions. **Results:** To date, 80 refractory metastatic solid tumor pts (n = 39 in dose esc; n = 41 in cohort expansions) have been treated, median age of 60 yrs, >70% treated with ≥ 3 prior lines of therapy, including >75% of treated pts with prior taxane exposure. Treatment has been well-tolerated with predominantly low-grade treatment-related adverse events (TRAEs) (Gr 1 & 2), such as fatigue (35%), alopecia (18%), decreased appetite (18%), dry eye (10%) & peripheral sensory neuropathy (PSN) (9%). Among 70 pts have sustained JK06-related Gr 3 adverse events (AEs): fatigue, malaise, gait disturbance, keratitis, vomiting, corneal ulcer, & PSN, that resolved, with two continuing treatment with dose reduction; no Gr 4 JK06-related AEs have been observed to date. Four pts underwent dose reductions, and five additional pts were discontinued due to TRAEs. Among 19 response-evaluable NSCLC pts to date, a 32% ORR has been observed, with 1 confirmed complete response (cCR), 4 confirmed partial responses (cPR) (one with CNS response) & 1 with unconfirmed partial responses (uPR), with the longest continuing therapy for 51 wks. Responses have been observed in adenomatous, squamous & EGFR mutant NSCLC pts. One of seven evaluable breast cancer pts (14% ORR) achieved a cPR and remained on treatment for >27 wks. **Conclusions:** To date, JK06 demonstrates promising emerging clinical activity in refractory NSCLC & breast cancer at multiple dose levels while being well tolerated without significant drug-related toxicities. Updated safety & clinical activity data from both dose escalation & expansion cohorts, including the initial assessment of dose randomization, will be presented. Clinical trial information: NCT06667960. Research Sponsor: None.

3039 Poster Session

Efficacy and safety of XNW27011, a Claudin-18.2 targeted (CLDN18.2) ADC, in advanced pancreatic ductal adenocarcinoma: A phase 2 study. First Author: Linlin Wang, Affiliated Hospital of Shandong First Medical University, Jinan, China

Background: Pancreatic ductal adenocarcinoma (PDAC) is an aggressive malignancy with a historically poor prognosis, the median overall survival (mOS) for PDAC patients (pts) who received ≥ 1 prior lines of standard treatments is only 6.2 to 7.4 months(mos). XNW27011 is a novel and potent Topoisomerase inhibitor (TOP1i)-based ADC targeting CLDN18.2. In preclinical studies, XNW27011 demonstrated antitumor activities in PDAC, supporting its progression into clinical development. Here, we report results of XNW27011 in pts with PDAC. **Methods:** The objectives of this phase 2 study were to evaluate the efficacy and safety of XNW27011 in PDAC, and to optimize doses for subsequent confirmatory trials. Pts with PDAC expressing CLDN18.2 (defined as ≥5% tumor cells with ≥2+ IHC staining) who had received prior systemic therapy were treated with XNW27011 at doses from 2.4 - 4.8 mg/kg, Q3W. The primary endpoint was ORR, secondary endpoints included TRAEs for safety, DCR, PFS, OS, and PK parameters. **Results:** As of Dec 29, 2025, a total of 48 pts had been enrolled with majority of them being enrolled in 3.0 mg/kg group. Among the 48 pts, the ECOG PS was 0 or 1, the median age was 59.0 years. 18 pts (37.5%) had received 1 prior line of systemic therapy. 22 pts (45.8%) had been treated with TOP1i. Efficacy: A total of 30 PDAC pts in the 3.0 mg/kg dose group were evaluable for efficacy. The ORR and DCR was 26.7% and 83.3%, respectively. mPFS and mOS was 4.1 and 10.0 mos, respectively. Among the 13 pts who had received only one prior line of therapy, the ORR was 46.2% and the DCR was 100.0%, mPFS was 4.4 mos, OS was not mature yet. However, the current mOS was 10.1 mos with the median follow-up of 8.1 mos. Detailed efficacy data are presented in the table. Among the pts who were previously treated with TOP1i, the median follow-up was 7.9 mos, the mPFS and mOS were 5.2 and 10.0 mos, respectively. Safety: Among the 48 PDAC pts, the incidence of treatment-related adverse events (TRAEs) was100.0%. The incidence of Grade ≥3 TRAEs and serious TRAEs were 77.1% and 58.3%, respectively. 35.4% and 6.3% of the TRAEs led to dose reduction and discontinuation, respectively. The most common TRAEs included nausea (77.1%), vomiting (64.6%), decreased appetite (64.6%) and anemia (62.5%). Pharmacokinetics: At doses of 0.6-6.0 mg/kg in patients with solid tumors including PDAC, the XNW27011 exposure (C_{max} and $AUC_{0-\infty}$) increased in an approximately dose proportional manner with a half-life of 5~7 days. Across all dose levels, circulating payload blood concentrations were low with 3.3% ADA positive rate. **Conclusions:** XNW27011 showed a manageable safety profile and encouraging survival outcome in pts with PDAC expressing CLDN 18.2, supporting its further clinical development as a promising therapeutic option for patients with PDAC expressing CLDN 18.2. Clinical trial information: NCT06792435. Research Sponsor: Evopoint Biosciences Co., Ltd.

3040 Poster Session

Safety, efficacy, and pharmacokinetics of XNW28012, a tissue factor antibody-drug conjugate (ADC) with topoisomerase 1 inhibitor (TOP1i) payload, in patients with advanced solid tumors: Results from a phase I/II study. First Author: Miaoyan Wei, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Tissue factor (TF) is overexpressed in a broad range of solid tumors including pancreatic ductal adenocarcinoma (PDAC). XNW28012 is the first TF ADC with a novel TOP1i payload. Here we report the safety and PK of XNW28012 in patients (pts) with solid tumors, and the efficacy in PDAC from a Phase I/II study. **Methods:** Eligible pts who failed standard therapy received XNW28012 Q3W. TF expression was not required for enrollment. The primary endpoints for dose escalation and expansion were safety and ORR, respectively. BOIN design was used for dose escalation. Eligible pts with PDAC and other solid tumors were enrolled at 2.0 and 2.4 mg/kg for dose expansion. **Results:** As of Nov. 21, 2025, 313 pts were enrolled (escalation: 16; expansion: 297), with median age of 56.3 yrs; 77.0% of ECOG 1; and 56.9% received ≥2 lines of prior systemic therapy. TEAEs in ≥20% pts were anemia (62.0%), stomatitis (60.1%), nausea (49.5%), WBC count decreased (47.0%), appetite decreased (43.1%), neutrophil count decreased (39.9%), vomiting (39.6%), asthenia (35.5%), weight decreased (30.7%), conjunctivitis (29.4%), rash (28.1%), hypokalemia (23.3%), hyponatremia (21.4%), and hypoalbuminemia (21.1%). ≥Grade 3 TEAEs in ≥5% pts were stomatitis (17.6%), neutrophil count decreased (14.4%), WBC count decreased (12.8%), anemia (11.5%), and lymphocyte count decreased (8.3%). Dose interruption, reduction and discontinuation due to TEAE occurred in 60.7%, 22.0%, and 3.8% of the pts, respectively. Grade 3 conjunctivitis was reported in 2.9% pts across the doses. Most common bleeding AE was epistaxis (12.1%), all grade 1/2. 1 pt at 3.6 mg/kg experienced DLT (grade 4 neutropenia, grade 3 stomatitis). 16 pts were enrolled in dose escalation from 0.6 to 3.6 mg/kg. ORR and DCR were 46.7% and 100%, respectively in 15 evaluable pts including PDAC, ovarian cancer, cervical cancer, and head and neck squamous cell carcinoma. In dose expansion, 45 and 48 PDAC pts were efficacy evaluable at 2.0 and 2.4 mg/kg, with a median follow up of 4.4 m and 6.0 m, respectively. Efficacy data in PDAC pts in dose expansion were summarized in the Table. PK data showed dose proportionality and very low payload exposure in the system indicating stable linker. **Conclusions:** XNW28012 demonstrated a manageable safety profile in heavily treated advanced solid tumor pts and promising anti-tumor activity in PDAC patients. The data support further development of XNW28012 in a broad range of solid tumors including PDAC. Clinical trial information: NCT06799637. Research Sponsor: Evopoint Biosciences Co., Ltd.

3041 Poster Session

Non-invasive MRD monitoring and profiling of clonal evolution by ctDNA in patients with advanced cancers treated within molecular tumor boards. First Author: Lavanya Ranganathan, German Cancer Consortium (DKTK), Partner Site Freiburg, a partnership between DKFZ and Medical Center - University of Freiburg, Freiburg, Germany

Background: Profiling of targetable genetic alterations within molecular tumor boards (MTB) guides for personalized treatment selection in patients with advanced cancers. During therapy, response is typically assessed by CT scans or MRI, which often have suboptimal sensitivity and specificity. Circulating tumor DNA (ctDNA) from blood plasma has emerged as a promising biomarker for noninvasive profiling of tumor mutational landscapes and disease monitoring. Here, we applied a pan-cancer next-generation sequencing (NGS) technology to assess the role of ctDNA for comprehensive tumor genotyping, early response prediction, and characterization clonal heterogeneity in patients receiving MTB recommended therapies. **Methods:** We developed and applied a custom targeted NGS approach (ExTARGET), which covers 266 genes across a 540 kb genomic region, to 157 plasma samples obtained at distinct milestones from 57 patients with diverse solid cancers. Plasma samples from healthy individuals (*n*= 24) were used to determine the specificity of our technology. **Results:** We identified variants in 96% of baseline plasma samples by ctDNA profiling, with a median of 7 mutations per patient (range: 1-41). Most frequently mutated genes included *KRAS* (35%), *BRAF* (24%), *ERBB2* (22%) and *TP53* (22%). Targetable tumor variants that led to treatment recommendations within the MTB were found non-invasively in 69% of patients. Longitudinal monitoring of baseline ctDNA variants in on-treatment samples, obtained early during therapy (*n*= 21), revealed that ctDNA dynamics were predictive of disease progression and preceded radiological/clinical progression in 8/19 (42%) patients. All patients with increasing ctDNA levels early during treatment showed radiologic disease progression in subsequent CT scans. On the other hand, an early decrease of ctDNA levels was associated with durable disease control in most patients and significantly favorable progression-free survival (*p*= 0.008; HR = 0.1, 95%CI: 0.02-0.6). Next, we explored temporal clonal heterogeneity in plasma samples collected from 16 patients with disease progression following MTB-recommended therapies. We observed substantial clonal evolution over time, with all samples harboring at least one emerging variant. Among these emerging alterations, 19% were classified as 'oncogenic' and 5% were identified as potentially targetable. **Conclusions:** We here developed an NGS-based technology for ctDNA profiling in heavily pretreated patients receiving MTB-recommended therapies. Non-invasive genotyping from plasma robustly identifies targetable aberrations and allows comprehensive tumor genotyping. Monitoring of ctDNA during treatment and at disease progression facilitates early prediction of treatment response and profiling of temporal clonal heterogeneity that could enable subsequent treatment selection. Research Sponsor: German Cancer Consortium (DKTK).

Performance of a tissue-free, molecular residual disease assay in colorectal, breast, and lung cancers from circulating tumor DNA. First Author: Princy Parsana, Natera, Inc., Austin, TX

Background: The Latitude test is a methylation-based, tissue-free molecular residual disease (MRD) test. In this study, we describe the improved performance of the assay in colorectal cancer (CRC) and its performance in an expanded set of indications including breast and lung cancer. **Methods:** The methylation-based, tissue-free ctDNA assay uses next-generation sequencing to query differentially methylated genomic regions in patients with CRC, breast, and lung cancer compared to cancer-free individuals in order to classify plasma samples as MRD positive (MRD+) or MRD negative (MRD-). Performance was evaluated in patients with cancer: CRC (N = 214), breast (N = 153), and lung (N = 148) with known ctDNA-positive results from Signatera (tumor-informed ctDNA testing) across a range of variant allele frequency (VAF) ranges, and cancer-free individuals (training set N = 531, validation set N = 200). Performance metrics, such as percent positive agreement (PPA) and specificity, were evaluated using cross validation in the cancer and cancer-free cohorts, respectively. **Results:** Among 214 CRC patients (VAF range: 0.003%-4.5%), PPA was 95.94% and specificity among all 200 cancer-free individuals was 99.50%. Among 153 breast cancer patients (VAF range: 0.002%-7.8%), PPA was 91.81%, which was maintained across subtypes, including HR+ (94.75%, N = 40), HER2+ (94.45%, N = 20), and triple-negative (87.94%, N = 29). Among the 164 cancer-free females, specificity of the breast tissue-free assay was 98.18%. Among 148 lung cancer patients (VAF range: 0.003%-5.8%), PPA was 92.63%, maintained across subtypes, including non-small cell lung cancer (92.54%, N = 112) and small cell lung cancer (95.23%, N = 25). Among all 200 cancer-free individuals, specificity of the lung tissue-free assay was 99.50%. **Conclusions:** These data demonstrate a high concordance between the Latitude tissue-free MRD assay and a clinically validated tumor-informed ctDNA assay across CRC, breast, and lung cancers, supporting the use of methylation-based biomarkers for informing prognosis and patient management. Research Sponsor: None.

Extracellular matrix-derived liquid biopsy for predicting response in patients with biliary tract cancer treated with nivolumab with or without ipilimumab combined with stereotactic body radiotherapy: Insights from the CheckPAC trial. First Author: Martin Birkmose Rasmussen, Nordic Bioscience, Copenhagen, Denmark

Background: Biliary tract cancer (BTC) is a rare malignancy with limited treatment options and poor prognosis. Although combined chemotherapy and immune checkpoint inhibitors are first-line treatment for advanced BTC, durable response is uncommon. Current immunotherapy biomarkers, such as PD-L1 expression, have limited utility and treatment response biomarkers are urgently needed. BTC is characterized by a fibrotic extracellular matrix, where widespread tumor fibrosis has been linked to immunosuppression and treatment resistance. In this study, we used Nordic ProteinFingerPrint Technology to evaluate the pharmacodynamic and predictive value of the FDA supported fibrosis biomarker NordicPRO-C3 (type III collagen pro-peptide) and the T-cell infiltration biomarker NordicC4G (granzyme B degraded type IV collagen) in patients with metastatic BTC treated with nivolumab with or without ipilimumab plus stereotactic body radiotherapy (SBRT). **Methods:** PRO-C3 (NordicPRO-C3) and C4G (NordicC4G) were measured at baseline and 60 days after treatment initiation in serum from 61 patients with BTC from the CheckPAC trial (NCT02866383). Patients received SBRT combined with nivolumab (n = 19) or nivolumab/ipilimumab (n = 42). The primary endpoint was clinical benefit rate (CBR; CR+PR+SD vs. PD) assessed by RECIST 1.1. Biomarker levels at baseline and biomarker changes during therapy were evaluated relative to response using Fisher's exact test; overall survival (OS) was assessed using uni- and multivariate Cox regression. **Results:** CBR was 0% in patients with high baseline PRO-C3 (243 ng/mL) versus 31% in patients with low PRO-C3 ($p < 0.05$). High PRO-C3 was associated with poor OS after adjusting for CA19-9, performance status, and modified Glasgow Prognostic Score (HR = 3.1, 95% CI 1.5-6.6, p = 0.004). Longitudinally, C4G increased significantly at day 60 in patients with clinical benefit ($p < 0.001$). CBR was 44% in patients with increased C4G versus 0% in those with decreased C4G (p = 0.007), and increased C4G was associated with improved OS (p = 0.01). All patients with clinical benefit had both increased C4G and low PRO-C3 at day 60. Among patients without clinical benefit, patients with increased C4G and low PRO-C3 and showed a trend towards improved OS (Median OS 8.3 months vs. 3.6 months, p = 0.08). **Conclusions:** High pre-treatment tumor fibrosis, quantified by elevated serum PRO-C3, is associated with poor response and OS in patients with BTC treated with SBRT plus immunotherapy. Changes in PRO-C3 and the T-cell infiltration biomarker C4G reflect pharmacodynamic changes, with increased C4G linked to improved outcome, particularly in patients with low PRO-C3. Together, these biomarkers may help to predict treatment response and guide clinical decision-making in BTC. Research Sponsor: None.

Prognostic impact of MRD positivity at ultra-sensitive ctDNA levels using a WGS-based personalized assay: A pan-cancer analysis from MONSTAR-SCREEN-3. First Author: Tadayoshi Hashimoto, National Cancer Center Hospital East, Kashiwa, Japan

Background: While circulating tumor DNA (ctDNA) demonstrates promise as a molecular residual disease (MRD) biomarker, its clinical implementation has been primarily limited to tumors with favorable ctDNA shedding characteristics. The MONSTAR-SCREEN-3 evaluates a whole-genome sequencing (WGS)-based MRD assay to assess MRD positivity at ultra-sensitive level beyond conventional WES-based MRD, including traditionally low-shedding tumors. **Methods:** MONSTAR-SCREEN-3 is a prospective multicenter study targeting 1,100 patients with solid tumors undergoing curative-intent treatment. Personalized panels were constructed using Precise MRD (Myriad Genetics), incorporating up to 1,000 tumor-specific alterations identified through WGS of matched tumor tissue. Serial plasma samples were collected at baseline, post-neoadjuvant treatment (NAT) (when applicable), 1-month (1M) post-surgery, every 3 months in year 1, and every 6 months thereafter up to 2 years. Assay performance was evaluated across multiple cancer types for ctDNA detection and recurrence monitoring. **Results:** Between May 2024 and November 2025, 1,088 patients across over 20 cancer types were enrolled, including colorectal (n=250), breast (n=156), cervical (n=95), gastric (n=88), and pancreatic (n=69) cancers. Treatment strategies included upfront surgery (n=704), NAT (n=296), and definitive chemoradiotherapy (n=96). Median follow-up was 5.3 months (range, 0–18.1). Baseline ctDNA detection was achieved in 96.2% (684/711), with 16.4% at ultra-sensitive levels (tumor fraction $<$100 parts per million [ppm]). Post-operative MRD positivity was 26.4% (163/617) at 1M and 23.8% (120/504) at 3M, with 46.0% and 41.7% detected at ultra-sensitive levels, respectively. Among 91 patients who received NAT and underwent pathological assessment, post-NAT MRD status demonstrated a sensitivity of 74.3% (55/74) and a specificity of 100% (17/17) for predicting pathological complete response ($P<0.01$). Among patients with available survival data, post-1M MRD positivity was associated with significantly worse disease-free survival (DFS) compared with MRD negativity (HR, 16.9; 95% CI, 8.2–34.8; $P < 0.001$). Furthermore, post-1M MRD positivity at levels below 100 ppm was associated with significantly inferior DFS compared with MRD negativity (HR, 8.2; 95% CI, 3.4–19.4; $P < 0.001$), whereas post-1M MRD positivity at levels $\geq$100 ppm was associated with significantly worse DFS compared with MRD positivity below 100 ppm (HR, 3.4; 95% CI, 1.7–6.7; $P < 0.001$). **Conclusions:** The WGS-based MRD assay demonstrated high baseline detection sensitivity and robust ultra-sensitive detection across diverse cancer types. Our findings show that post-1M MRD positivity below 100 ppm at ultra-sensitive level is prognostic for recurrence risk. Updated molecular and clinical outcome data will be presented. Comprehensive genomic profiling of matched ctDNA and tissue from patients with four common cancers enrolled to the NCI-MATCH trial. First Author: Rini Pauly, Molecular Characterization Laboratory, Frederick National Laboratory for Cancer Research, Frederick, MD

Background: In the NCI-MATCH trial (NCT02465060), tumor tissue from 5,954 patients with advanced cancers underwent next-generation sequencing using the Oncomine Comprehensive Assay v2 (OCAv2) to determine eligibility. Most tumors lacked a qualifying mutation of interest (MOI) for assignment. Plasma from 1,301 patients with common cancers – [colorectal (COADREAD), breast (BREAST), non–small cell lung (NSCLC), and prostate (PRAD) (OncoTree codes are shown in parentheses)] was analyzed to characterize circulating tumor DNA (ctDNA) and assess its utility for detecting clinically relevant MOIs. **Methods:** Cell-free DNA was extracted from plasma collected in Streck tubes at enrollment. ctDNA profiling was performed using the NCI ctDNA Research v2 assay (523 genes) on the Illumina NovaSeq 6000. Matched tumor tissue was analyzed using OCAv2 (143 genes). Positive percent agreement (PPA) was calculated using tissue as the reference. Blood-based microsatellite instability (bMSI) was assessed across ~2,400 loci, with bMSI-high (bMSI-H) defined as sum Jensen-Shannon Distance (sumJSD) $\geq$0.2. Blood-based tumor mutation burden (bTMB) was defined as total SNVs and indels per Mb. **Results:** Of 1,301 patients, 1,148 (88%) yielded evaluable ctDNA results (COADREAD, n=487; BREAST, n=367; NSCLC, n=220; PRAD, n=74). Overall PPA with matched tissue was 90.3%. Discordant samples had significantly lower median tumor fraction by maximum somatic allele frequency (MSAF; 0.39%) than concordant samples (12.04%). Median MSAF by histology was 14% (COADREAD), 7% (BREAST), 8% (NSCLC), and 5% (PRAD). Clinically relevant fusions detected exclusively in ctDNA included *RET* (1% NSCLC), *EML4::ALK* (2% NSCLC), *FGFR2* (1% COADREAD; 2% BREAST), and *NTRK1* ($<$1% COADREAD and BREAST), corresponding to actionable NCI-MATCH arms [*FGFR2/3* - arm K (erdafitinib), *ALK* - arm F (crizotinib), *NTRK* - arm Z1E (larotrectinib)]. Actionable ctDNA-only mutations in PRAD included *ATM* and MLH1. Twenty-eight cases were bMSI-H (MSAF $\geq$0.02; sumJSD $\geq$0.2), of which 13 were mismatch repair-deficient by tissue testing (MLH1/MSH2 nuclear stain-negative). bMSI-H was most frequent in COADREAD (7%). Ten cases (seven COADREAD, two NSCLC, one PRAD) were MMR-proficient by tissue but bMSI-H by ctDNA. Twenty-four cases had high bTMB ($\geq$20 mut/Mb; MSAF $\geq$0.02), all of which were also bMSI-H. **Conclusions:** ctDNA - tissue concordance NCI-MATCH in these four cancer histologies was high (90.3%), supporting liquid biopsy as a practical alternative when tissue is unavailable. Detection of ctDNA-only alterations highlights tumor heterogeneity in advanced cancers and identifies additional therapeutic opportunities. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health.

Incremental clinical yield of serial large NGS panel liquid biopsies in routine care: Analysis of the STING study. First Author: Camille Mazza, Institut de Cancérologie Godinot, Reims, France

Background: Plasma ctDNA profiling is increasingly repeated over the disease course to capture tumor evolution and newly targetable alterations. However, the incremental clinical yield of serial ctDNA profiling in routine practice remains incompletely characterized. **Methods:** This analysis was conducted within the prospective STING study (ClinicalTrials.gov identifier: NCT04932525), a program that aims to identify actionable molecular targets in patients with advanced solid tumors. Eligible patients were adults with advanced solid tumors and provided written informed consent for molecular analyses. Circulating tumor DNA (ctDNA) profiling was performed using an FDA-approved hybrid-capture next-generation sequencing assay, enabling to analyze over 300 genes, and assessment of tumor mutational burden (TMB) and microsatellite instability (MSI) from plasma samples. All molecular results were reviewed during a weekly institutional Molecular Tumor Board to assess clinical relevance and therapeutic implications. For the present study, patients with ≥2 FMI liquid biopsies were included. The earliest ctDNA test was defined as baseline (BL1), and the second earliest as BL2. Actionable alterations were classified according to the ESMO Scale for Clinical Actionability of Molecular Targets (ESCAT). The primary objective was to determine the proportion of patients in whom repeat ctDNA testing identified new actionable alterations not detected at BL1, and their ESCAT tier distribution. **Results:** Among 1,565 patients (3,494 liquid biopsies), the median number of tests per patient was 2 (range 2–6). The most common tumors were lung (26.4%), breast (13.1%), prostate (10.9%), colorectal (CRC) (8.0%), pancreas (6.7%), and thyroid (4.1%). The median BL1→BL2 interval was 313.5 days (range 2–2,279). At BL1, 470 patients (30.0%) harbored ≥1 actionable alteration (ESCAT I–III); excluding TMB-high, 23.9%. Repeat testing identified ≥1 *new* actionable alteration in 316 patients (20.2%); excluding TMB-high, 10.7%. Notably, 227 patients (14.5%) converted from no actionable alteration at BL1 to ≥1 actionable alteration on later testing (8.1% excluding TMB-high). Newly detected actionable alterations were distributed as ESCAT II (54.3%), ESCAT I (26.1%), and ESCAT III (19.7%); 93 patients (5.9%) gained at least one new ESCAT I alteration. The yield of new actionable alterations varied by tumor type (~29% CRC, 25.9% breast, 23.5% lung, 14.6% prostate). **Conclusions:** In a large real-world cohort, serial ctDNA testing provided clinically meaningful incremental detection of actionable alterations in ~1 in 5 patients, including new ESCAT I findings in ~6%. These data support serial ctDNA profiling to capture evolving tumor genomics and expand therapeutic opportunities. Prospective studies should define optimal timing and confirm downstream clinical impact. Research Sponsor: None.

Cell-free DNA (cfDNA) methylation-based multi-cancer early detection (MCED) assay to enable subtyping of lung cancer, breast cancer, and non-Hodgkin lymphoma (NHL). First Author: Kezhong Chen, Thoracic Oncology Institute and Department of Thoracic Surgery, Peking University People's Hospital, Beijing, China

Background: Given that distinct pathological and molecular subtypes of most cancers correspond to different treatment strategies, accurate cancer subtyping is clinically critical. Currently, pathological and molecular subtyping relies primarily on tissue biopsy—a procedure that is not always clinically feasible. Additionally, tumor heterogeneity may compromise the accuracy of subtyping via this approach. Prior studies have shown that cfDNA methylation-based detection is tissue-independent and outperforms mutation-based assays in cancer subtyping. Here, we employed a previously developed targeted methylation MCED assay to further classify the subtypes of lung cancer, breast cancer, and NHL. **Methods:** Pretreatment blood samples from lung cancer, breast cancer, and NHL patients enrolled in a MCED study were analyzed via the targeted methylation assay. Only samples with detected circulating tumor DNA (ctDNA) were included. The training cohort comprised lung cancer (n=529: 227 adenocarcinomas, 191 squamous cell carcinomas, 111 small cell carcinomas), breast cancer (n=359: 92 triple-negative breast cancers [TNBC], 267 non-TNBC cases), and NHL (n=157: 145 B-cell lymphomas, 12 T-/NK-cell lymphomas). The validation cohort included lung cancer (n=194: 87 adenocarcinomas, 82 squamous cell carcinomas, 25 small cell carcinomas), breast cancer (n=87: 26 TNBC, 61 non-TNBC cases), and NHL (n=60: 48 B-cell lymphomas, 12 T-/NK-cell lymphomas). cfDNA methylation profiles were analyzed to further classify the subtypes of these three malignancies. **Results:** In the validation cohort, the lung cancer classification model exhibited high overall accuracy 91.8% (178/194), with subtype-specific accuracies of 94.3% (82/87) for adenocarcinoma, 89.0% (73/82) for squamous cell carcinoma, and 92.0% (23/25) for small cell carcinoma. The breast cancer model achieved an overall accuracy of 80.5% (70/87), including 65.4% (17/26) for TNBC and 86.9% (53/61) for non-TNBC. For NHL, the model yielded an overall accuracy of 96.7% (58/60), with 97.9% (47/48) for B-cell lymphoma and 91.7% (11/12) for T-/NK-cell lymphoma. **Conclusions:** The cfDNA methylation-based MCED assay facilitates accurate subtype prediction for common malignancies without the need for invasive tissue biopsy procedures. This assay achieves high accuracy in lung cancer and NHL, whereas relatively lower accuracy is observed for breast cancer, particularly TNBC, owing to its reliance on molecular subtyping. Future studies will validate this assay in larger cohorts and extend its utility to a broader spectrum of cancer types. Research Sponsor: Shanghai Xiaohe Medical Laboratory Co. Ltd.

Correlation of presurgical circulating tumor DNA (ctDNA) levels with pathologic (p) stage and lymph node (LN) burden in localized colon cancer. First Author: Masahito Kotaka, Sano Hospital Gastrointestinal Cancer Center, Kobe, Japan

Background: Accurate preoperative staging is vital for tailoring neoadjuvant therapy (NAT) in localized colon cancer. However, clinical staging often diverges from pathological findings due to limitations of imaging modalities in assessing pathologic LN (pLN) involvement and inter-observer variability. This study evaluated the association between presurgical ctDNA levels, microsatellite instability (MSI) status, and pLN burden across pStages I–III in colon cancer. **Methods:** This retrospective study included patients (pts) with pStage I-III colon cancer from the GALAXY study with available presurgical ctDNA levels (mean tumor molecules/mL; MTM/mL) assessed by a personalized tumor-informed assay (Signatera, Natera, Inc). Key exclusions included receipt of NAT, inconsistent pLN classification, pN1c disease, and missing MSI status. Conditional inference tree modeling was used to hierarchically evaluate clinicopathologic and molecular risk factors for their association with presurgical ctDNA levels. **Results:** Of the 3,473 pts (14.4%, 43.1% and 42.5% with pStage I, II and III, respectively) included, 90.2% had microsatellite stable (MSS) tumors. The conditional inference tree partitioned the cohort into five subgroups of distinct presurgical ctDNA level distributions defined by pStage, pLN burden, and MSI status, and demonstrated the pStage to be the strongest determinant of presurgical ctDNA levels. pStage I pts had uniformly low MTM/mL. In contrast, pStage II–III pts had higher and more variable MTM/mL levels, which were stratified by pLN burden and further differentiated by MSI status within each nodal category. Presurgical ctDNA levels were significantly higher in pLN-positive vs pLN-negative pts (median 2.52 vs 1.23 MTM/mL, $p < 0.0001$) and in pStage IIB-III vs pStage I-IIA pts (median 2.64 vs 1 MTM/mL, $p < 0.0001$). While presurgical ctDNA levels did not differ significantly based on MSI status alone, within both MSS and MSI-H subgroups, they were significantly higher in pLN-positive pts vs pLN-negative pts (MSI-H: median 4.40 vs 1.19 MTM/mL; MSS: median 2.41 vs 1.25 MTM/mL). Similar results were observed when grouped based on pStage I/II vs III. Specifically among pLN-positive pts, presurgical ctDNA levels increased with higher pLN burden (MSI-H: median 15.13 vs 3.75 MTM/mL for ≥4 vs 1-3 LN, p=0.049; MSS: median 3.70 vs 1.96 MTM/mL for ≥4 vs 1-3 LN, $p<0.0001$). **Conclusions:** Presurgical ctDNA levels reflect a hierarchical interplay of pathologic stage, lymph node burden, and MSI status rather than any single clinicopathologic factor. High presurgical ctDNA levels reliably correlated with pStage and pLN positivity in localized colon cancer, supporting the development of models incorporating presurgical ctDNA quantification to better select pts for NAT and their evaluation in prospective trials. Clinical trial information: 000039205. Research Sponsor: None.

Clinical utility of liquid *KRAS*-mutation screening in advanced pancreatic cancer patients referred for early-phase trials. First Author: Erick F. Saldanha, Divison of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada

Background: Approximately 90% of pancreatic ductal adenocarcinomas (PDAC) harbor a KRAS mutation. Clinical trials targeting oncogenic *KRAS* mutations, including mutant-specific, pan-KRAS/-RAS inhibitors, have shown promising activity. As tissue next-generation sequencing (NGS) is a multi-step process that can affect turnaround time (TAT), a liquid biopsy (LB) approach is of interest. We investigated the clinical utility of LB testing for common *KRAS* variants to facilitate matching pts with PDAC to early phase trials. **Methods:** In this single-center, prospective enrollment/retrospective analysis study, we included pts with locally advanced (LA) or metastatic PDAC seen at Princess Margaret Cancer Centre (PM) phase I clinical trials and gastrointestinal (GI) cancer clinics between Jan 2025 - Jan 2026. Medical records were reviewed to collect clinicopathologic characteristics and treatment data. Plasma ddPCR assessed 4 *KRAS* codon 12 variants (G12C/D/R/V) at the CAP-CLIA-accredited Advanced Molecular Diagnostics Laboratory at PM. TATs for KRAS ddPCR vs tissue NGS were compared using the Wilcoxon signed-rank test. **Results:** Of 98 pts with LA/metastatic PDAC, the median age was 67 years, 59% were male, and 67 pts were ECOG 1 (88%). 84 pts had disease stage IV (86%), 43 (44%) pts were chemotherapy-naïve, and 33 (34%) pts had 1 prior L of therapy. Median number of metastatic sites was 2 (range [r] 1-5), and median CA19-9 was 343 (IQR 35-1767). *KRAS* G12 mts were detected by ddPCR in 38% (37/98) of pts: G12D (46%), G12V (46%), G12R (5%), G12C (2.7%). The median ddPCR VAF was 4.8% (r: 0.4 - 42.2), median TAT of 5 days (r: 1 - 8). Among pts with *KRAS* detected by ddPCR, 4 (11%) were enrolled in phase I trials targeting *KRAS*. Tissue NGS was performed in 40 pts (41%), KRAS was detected in 90% (36 pts), with a median VAF of 45% (r: 5-90), and median TAT of 54 days (r: 10-92; $p<0.0001$ compared to ddPCR TAT). Reported *KRAS* variants: G12D (50%), G12V (19.4%), G12R (19.4%), Q61H (8.3%), G12C (2.8%). Co-mts in TP53 were seen in 22/36 pts (61%). Concordance between ddPCR and tumor NGS metrics are shown in Table 1. Median NGS VAF of concordant vs discordant cases: 48% vs 21% (p=0.047). **Conclusions:** Plasma-based *KRAS* screening using ddPCR was significantly faster than tissue NGS in advanced PDAC. A liquid-first strategy can accelerate matching pts to RAS-targeted trials, but intense competition for trial allocations limits access to these agents. ddPCR has excellent specificity and PPV across *KRAS* variants but limited sensitivity, thus serves as a rapid rule-in assay. Tissue NGS remains relevant, especially in ddPCR negative pts, and to assess co-mutations. Research Sponsor: None.

N=36 pts	ddPCR(+/-)	NGS (+/-)	Sens	Spec	PPV	NPV	Concordance	Discordance
G12C	1 / 35	1 / 35	100%	100%	100%	100%	100%	0%
G12D	11 / 25	18 / 18	61%	100%	100%	72%	81%	19%
G12R	1 / 35	7 / 29	14%	100%	100%	83%	84%	16%
G12V	5 / 31	6 / 30	83%	100%	100%	97%	97%	3%

ctDNA kinetics throughout first-line AI and palbociclib using a tumor-informed structural variant-based ctDNA assay: Retrospective analysis of PADA-1 samples. First Author: Luc Cabel, Institut Curie, Paris and Saint-Cloud, France

Background: With standard assays (Limit of Detection [LoD95] at or >100 PPM), most patients with ER+/HER2- mBC show ctDNA "clearance" within a few weeks after initiating first- line AI+CDK4/6i, with ctDNA becoming detectable again only at or shortly before progression. To gain a more comprehensive view of ctDNA kinetics in response to therapy, we analyzed serial plasma samples from PADA-1 using a tumor-informed assay with a 100-1,000-fold higher sensitivity (LoD95 <10PPM). **Methods:** PADA-1 allowed the collection of plasma at baseline and every two months during first-line AI+palbociclib (PAL). A total of 489 serial plasma samples from 45 patients in PADA-1 were analyzed using an ultrasensitive structural variant-based ctDNA assay. WGS was performed on tumor material from archival primary or metastatic biopsies, and personalized multiplex dPCR assays tracking up to 16 somatic structural variants were used for ctDNA monitoring. **Results:** At baseline, before AI+PAL start, ctDNA was detected in N=40/41 evaluable patients (98%). ctDNA remained detectable in 381/489 (78%) samples during therapy. ctDNA was persistently detectable and quantifiable (i.e. detected at all timepoints) throughout first-line therapy in most initially positive patients (24/40, 60%). With this ultra-sensitive assay, we report, for the first time, that ctDNA follows a recurrent kinetic pattern: (1) a steep decrease during the first 6 months of treatment, (2) a nadir reached at 6–12 months, and (3) a continuous increase until radiological disease progression (or discontinuation of follow-up). In some patients (15/40, 38%), ctDNA became undetectable at some point during therapy despite the high sensitivity of the assay, with sustained ctDNA clearance associated with no risk of impending tumor progression. **Conclusions:** Serial analyses with a highly sensitive ctDNA test uncover the molecular trajectory of tumor response to first line AI+PAL. The presence of an early ctDNA nadir, followed with a later slow and continuous increase of ctDNA, prior to radiological progression, highlights the dynamic nature of ER+ HER2- mBC response to therapy. This approach can complement imaging-based disease monitoring, extends the clinical utility of ctDNA monitoring beyond individual mutations, and opens new perspectives of therapeutic interventions and treatment adaptation. Clinical trial information: NCT03079011. Research Sponsor: Pfizer; SAGA Diagnostics.

Tumor-of-origin prediction using methylation signals from plasma cell-free DNA (cfDNA): Real-world experience in Asia and the Middle East (AME). First Author: Ankur Bahl, Fortis Memorial Research Institute Gurugram, Gurugram, India

Background: Accurate identification of tumor tissue of origin (TOO) is essential for guiding treatment decisions in advanced cancers; however, tissue biopsies may be limited by accessibility, sample adequacy, or diagnostic delays. Plasma cfDNA-based methylation profiling provides a non-invasive approach for TOO determination and has demonstrated high agreement with clinicopathologic diagnoses in prior studies. However, real-world data from AME remains limited. We evaluated the real-world performance of a methylation-based TOO classifier using plasma cfDNA in this population. **Methods:** We retrospectively analyzed plasma cfDNA samples from patients with advanced solid tumors tested across AME using the Guardant360 Liquid assay through December 2025. The assay interrogates epigenomic signals from >19,000 methylated regions. The TOO classifier assigns a ranked cancer signal of origin (CSO) based on tumor-specific methylation patterns, reporting a primary CSO prediction and, when confidence is intermediate, a secondary CSO prediction. CSO confidence is quantified algorithmically based on methylation signal strength and classification certainty. Only samples with medium (50–80%) or high (>80%) confidence predictions were included. All tests were ordered as part of routine clinical care, and available clinicopathologic diagnoses (CPD) served as the reference standard. **Results:** Among 1,782 cfDNA-profiled samples, 1,230 (69%) yielded a CSO prediction with medium or high confidence. The primary CSO prediction matched CPD in 85% of cases overall, increasing to 91% when secondary CSO predictions were included. Tumor-type–specific accuracy varied, with the highest performance observed for colorectal, breast, and prostate cancers (94% each). Agreement with CPD was lower for gastroesophageal (72%) and kidney cancers (68%). Among 114 cancer of unknown primary (CUP) cases, a suspected clinical diagnosis was available for 48. Medium- or high-confidence CSO predictions were generated in 42 (87%). CSO predictions aligned with subsequent clinicopathologic consensus or confirmatory biopsy in 35 (83%), spanning 13 tumor types, most commonly lung cancer (24%). Therapy response evaluation was available for 12 patients, with partial response in 9 (75%) and stable disease in 3 (25%). **Conclusions:** In this real-world AME cohort, the TOO classifier identified probable tumor tissue of origin in most advanced cancer patients. CSO predictions showed high agreement with CPD across multiple tumor types. This approach demonstrated potential value in resolving CUP cases, with the predicted origin confirmed in 83% of evaluable patients. These findings support the clinical feasibility of methylation-based tumor-of-origin testing in AME and warrant further studies to evaluate its impact on clinical decision-making. Research Sponsor: Guardant Health Pte. Ltd., Singapore.

Tissue-free minimal residual disease evaluation and clinical utility in early breast cancer: A real-world study. First Author: Tanmayi Pai, Winship Cancer Institute of Emory University, Atlanta, GA

Background: Minimal residual disease (MRD) detected using circulating tumor DNA (ctDNA) is associated with increased breast cancer (BC) relapse risk in patients (pts) with early BC after curative-intent surgery. However, the clinical utility of ctDNA-based MRD testing for post-surgical surveillance and risk stratification remains incompletely defined. We used real-world data to evaluate the performance of Guardant Reveal, a tissue-free epigenomic assay for MRD detection, and the clinical significance of a positive MRD test (+MRD) in pts with resected early BC. **Methods:** Data of pts with resected stage I-IIIA BC in the Guardant InfinityAI Data Library who underwent Guardant Reveal testing between February 2023 and September 2025 was analyzed. Pts with ≥1 post-surgical MRD were included if they had either no distant metastatic BC recurrence with ≥1 year of follow up after the last MRD test or a documented distant metastatic BC postoperatively; pts with a new non-breast primary malignancy were excluded. Sensitivity was assessed by site of distant metastasis and interval from MRD test to recurrence; nodal recurrences were excluded due to claims data limitations. Specificity was assessed using all tests from pts without recurrence and ≥1 year of follow up after the last post-treatment MRD test. Claims data were used to infer treatment changes following +MRD. **Results:** A total of 822 pts was analyzed. 114 pts with real-world clinico-genomics data were evaluable for sensitivity and 708 for specificity. One-year sensitivity for distant metastatic recurrence was 71%, and was highest for bone-only (97%, 35/36 cases) or lung (89%, 8/9 cases) recurrences and lowest for brain-only recurrences (33%, 1/4 cases). Sensitivity within 12 months of recurrence was higher in hormone receptor-positive (HR+)/HER2-negative BC (79%) and stage IIIA BC (81%) and for multiple-organ versus single-organ metastasis (83% versus 69%). Sample-level specificity was 94%. Following +MRD, 41 pts did not initiate or switch systemic therapy; 29 had distant BC recurrence, including 24 within 90 days after +MRD. Twenty pts switched therapy within 90 days of +MRD; 19 recurred, including 17 within 90 days after +MRD. Among 10 pts with post-recurrence MRD testing, only 3 had +MRD. **Conclusions:** In a real-world cohort of pts with resected early-stage BC, a tissue-free epigenomic ctDNA MRD assay demonstrated high specificity and clinically meaningful sensitivity for distant metastatic recurrence, particularly for bone-only and lung metastases and in pts with HR+ BC. These findings support ctDNA-based MRD testing as a noninvasive tool for postsurgical surveillance and risk stratification in early BC. Research Sponsor: None.

Early ctDNA dynamics assessed by a personalized whole-genome sequencing-based assay as a predictor of outcomes with immune checkpoint blockade in advanced melanoma. First Author: Mora Guardamagna, Department of Cancer Medicine, Gustave Roussy Cancer Campus, Villejuif, France

Background: Circulating tumor DNA (ctDNA) is an emerging biomarker for assessing treatment outcomes and monitoring disease recurrence in melanoma. However, evidence supporting its clinical utility at very early on-treatment timepoints remains limited. We evaluated whether ctDNA dynamics relative to a single cycle of immune checkpoint blockade (ICB) are associated with treatment outcomes in patients (pts) with advanced melanoma. **Methods:** In this prospective, single-center cohort, pts with unresectable stage III or IV melanoma were enrolled. Treatment included anti-PD1 monotherapy (n=22, 40%) or anti-PD1+anti-CTLA-4 therapy (n=33, 60.0%). ctDNA analysis was performed using a personalized, tumor-informed assay (Signatera Genome, Natera, Inc.) designed from WGS of matched tumor and normal pairs. ctDNA (reported in mean tumor molecules per mL, MTM/mL) was subsequently tracked in the pts' longitudinal blood samples, which were collected at baseline (T0) and prior to cycle 2 (T1; 3-4 weeks after ICB initiation). ctDNA dynamics were categorized as favorable (ctDNA clearance at T1 or >10-fold decrease from T0 to T1) or unfavorable (rising ctDNA or <10-fold decrease from T0 to T1). Associations between these categories and progression-free survival (PFS) and overall survival (OS) were assessed using Kaplan-Meier estimates and Cox proportional hazards models. **Results:** A total of 55 pts with unresectable stage III (n=12, 21.8%) or stage IV (n=43, 78.2%) melanoma were included. Median follow-up was 36.43 months (mo) (range, 31.47-41.39). ctDNA-positivity was 83.6% (46/55) at baseline and 80.0% (44/55) at T1. Table 1 summarizes survival outcomes per ctDNA profile. Pts with an unfavorable profile (UP) of ctDNA dynamics experienced worse PFS and OS in contrast to those with a favorable profile (FP). Median PFS was 2.1 mo in the UP group versus 28.8 mo in the FP group; median OS was 19.3 vs 37.8 mo, respectively. All pts (n=21, 100%) with progressive disease had an UP, including 52.3% (11/21) with rising ctDNA and 47.7% (10/21) with <10-fold decrease. Median ctDNA levels at T1 were also higher in pts without objective response compared with responders (56.69 vs 0.38 MTM/mL; p<0.001). **Conclusions:** ctDNA dynamics assessed by a personalized WGS-based assay after a single cycle of ICB were strongly associated with response and survival outcomes in advanced melanoma. These findings support the evaluation of treatment-adaptation strategies based on early ctDNA dynamics in pts receiving immunotherapy. Research Sponsor: None.

ctDNA profile	median PFS (mo)	6-mo PFS	12-mo PFS	PFS HR (95%CI) p-value	median OS (mo)	6-mo OS	12-mo OS	OS HR (95%CI) p-value

A population tumor kinetics analysis for early-cycle ctDNA-guided therapy decisions in DLBCL. First Author: Kunhee Kim, University of Connecticut School of Medicine, Hartford, CT

Background: Early circulating tumor DNA (ctDNA) kinetics may be instrumental in identifying patients with DLBCL who can safely discontinue therapy after three cycles, as well as those who are less likely to benefit from completing the full six cycles. However, the optimal timing for ctDNA measurement, added value of early cycle data, and influence of assay sensitivity remain uncertain. Through population tumor kinetics (pop-TK) modeling of Pola-R-CHP (Pomeroy et al., Blood Cancer Discovery, 2025), we evaluated how adding data from cycles 1 and 2 enhances risk stratification beyond the assessment conducted after cycle 3. **Methods:** A 5-drug pop-TK model calibrated to Pola-R-CHP single-agent sensitivity distributions and clinical outcomes simulated tumor cell populations and patient-level parameters. Predicted residual disease after each cycle was mapped to ctDNA titers under assays of varying detection thresholds, representing conventional ctDNA, high-sensitivity ctDNA, and PET. We evaluated (1) ctDNA negativity at cycle three only, (2) adding cycles 1 and 2 for prediction, and (3) using cycles 1 and 2 to identify non-responders. For detection thresholds, representative values were selected to reflect overall trends. **Results:** Among ctDNA-negative patients at cycle 3 (n=557), stopping therapy at cycle 3 led to a recurrence rate of 0.172, while completing six cycles eliminated all recurrences. Adding ctDNA from cycles 1 and 2 separated cycle 3-negative patients into a high-risk group with much higher recurrence (90/121; 0.744) and a low-risk group with very low relapse risk (6/436; 0.014). Across assay sensitivities, high-sensitivity ctDNA reduced recurrence after cycle 3 cessation to 0.093 (43/464), whereas PET-level sensitivity showed a higher recurrence rate (0.288; 171/593), and adding data from cycles 1 and 2 consistently improved sensitivity. Early-cycle ctDNA (C1, C2) stratified patients into a high-risk non-responder group (5-year PFS 0.009), who can benefit from transferring treatment plans, and a low-risk group with favorable outcomes (5-year PFS 0.961). **Conclusions:** Pop-TK modeling suggests that although most patients with cycle 3 ctDNA negativity do not relapse when treatment is continued through cycle 6, some patients may still experience relapse that might not have occurred if treatment had been completed through cycle 6. Adding early cycles produces a large low-risk subgroup, supporting safer de-escalation, while still identifying patients who will consistently relapse if therapy is stopped early. Higher assay sensitivity reduces false negatives, but early-cycle ctDNA remains very informative. Furthermore, early cycle ctDNA enables identification of non-responding patients before completion of therapy. These findings support the addition of early cycle ctDNA into response-adapted de-escalation and early treatment switching in trials for DLBCL treated with Pola-R-CHP. Research Sponsor: None.

Multi-omics discovery and clinical validation of COL1A2 alternative splicing isoforms as liquid biopsy markers for metastasis surveillance in osteosarcoma. First Author: Junqiang Yin, Department of Musculoskeletal Oncology Center, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Osteosarcoma (OS) is characterized by early metastatic dissemination, yet the lack of sensitive and tumor-specific tools for real-time surveillance remains a major barrier to improving patient outcomes. **Methods:** We performed an integrative multi-omics analysis of 424 OS patients, incorporating whole-exome sequencing, bulk RNA sequencing, short-read single-cell RNA sequencing, and single-cell long-read transcriptomics to resolve isoform-level AS alterations at single-cell resolution. Candidate isoforms were evaluated across plasma and peripheral blood datasets from 346 healthy controls to assess tumor specificity. Translational utility was tested in a prospective clinical trial (ChiCTR2400079438), comparing COL1A2 isoform–based circulating tumor cells (CTCs) detection with conventional VIM/TWIST1-based CTC assays and tumor-informed circulating tumor DNA (ctDNA) profiling. **Results:** OS exhibited widespread alternative splicing dysregulation across both tumor and stromal compartments, with extensive isoform remodeling revealed by single-cell long-read transcriptomics. Two metastasis-associated COL1A2 isoforms were detected in 98% of OS tumor cells but were entirely absent in healthy controls, demonstrating high tumor specificity. COL1A2 isoform–based CTCs detection significantly outperformed VIM- or TWIST1-based assays for predicting metastasis (AUC 0.833 vs. 0.531, $P < 0.01$) and achieved accuracy comparable to circulating tumor DNA (ctDNA) assays (AUC 0.833 vs. 0.861, P = 0.78). Notably, COL1A2 isoform–based CTCs detected metastatic progression 5.11 months earlier than conventional imaging, approximately two months earlier than ctDNA. Longitudinal analyses further revealed frequent loss of primary tumor–derived mutations during metastatic evolution, limiting the sensitivity of tumor-informed ctDNA assays, whereas COL1A2 isoform–based CTC detection remained robust. **Conclusions:** Collectively, this study provides the first systematic comparison of CTCs- and ctDNA-based surveillance strategies in OS and establishes COL1A2 isoform-based CTCs detection as a sensitive, specific, and mutation-agnostic liquid biopsy strategy. Clinical trial information: ChiCTR2400079438. Research Sponsor: None.

Integrating tumor mutation profiles, preoperative circulating tumor DNA (ctDNA), and clinical features to a predicting model for early peritoneal recurrence in stage II-III gastric cancer following curative gastrectomy. First Author: Quang Thong Dang, Department of Gastrointestinal Surgery, University Medical Center, University of Medicine and Pharmacy at Ho Chi Minh City, Ho Chi Minh, Viet Nam

Background: Peritoneal recurrence is the common failure pattern after curative gastrectomy and is most consequential within the first 2 years. Early risk identification can alter treatment strategy. Conventional clinicopathologic models are inadequate for individualized early detection. Tumor-informed circulating tumor DNA (ctDNA) enables detection of minimal residual disease (MRD) and may help refine risk stratification. **Methods:** We conducted a prospective cohort study of 134 patients with stage II–III gastric adenocarcinoma undergoing curative-intent gastrectomy (MRD cohort). Clinicopathologic variables, tumor mutation profiles, and ctDNA metrics were integrated to train and internally validate machine-learning models using logistic regression, random forest, and XGBoost for the primary endpoint of peritoneal recurrence within 12 months and 24 months after surgery. External validation was performed using the Yang et al. dataset. **Results:** Among 134 MRD patients with complete molecular and clinical data, 19 (14.2%) and 35 (26.1%) developed peritoneal recurrence within 12 months and 24 months, respectively. ctDNA positivity and higher max variant allele frequency (max VAF) were strong predictors of early peritoneal relapse, with additional contributions from pathologic stage and preoperative CEA, PI3K–AKT or EMT pathway genes. Across algorithms, ctDNA-integrated models consistently outperformed clinical-only baselines, with XGBoost showing the best overall discrimination on cross-validation. Findings generalized on external validation with the Yang et al. dataset, supporting model transportability. **Conclusions:** Integrating tumor-informed ctDNA with clinical and genomic features enables actionable prediction of early peritoneal recurrence after curative gastrectomy. This tool can trigger strategy modification of either stricter follow-up, adjuvant therapy intensification, or consideration of neoadjuvant approaches, in selected high-risk patients. Multicenter validation and prospective utility studies are warranted. Clinical trial information: NCT05029869. Research Sponsor: None.

A prospective study of tumor-informed ctDNA minimal residual disease detection in bone and soft tissue sarcomas. First Author: Junqiang Yin, Department of Musculoskeletal Oncology Center, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: The high recurrence and metastasis rates lead to poor survival of patients with sarcoma. Conventional imaging often detects relapse at a relatively late stage. In our previous study, circulating tumor DNA (ctDNA)-based minimal residual disease (MRD) detection demonstrated strong prognostic value in osteosarcoma, enabling earlier detection of recurrence compared with radiographic surveillance. However, whether this approach is applicable to soft tissue sarcomas and the broader sarcoma population remains unclear. **Methods:** Between August 2020 and March 2024, patients with sarcoma were prospectively enrolled at a single center. Tumor-informed MRD assays were designed using whole-exome sequencing of paired tumor–normal samples. Longitudinal postoperative plasma samples were collected for ctDNA analysis. Survival outcomes were assessed using Kaplan–Meier analysis with log-rank tests. Multivariable Cox proportional hazards regression was performed adjusting for age, sex, tumor necrosis score, and histologic subtype (osteosarcoma vs non-osteosarcoma). **Results:** A total of 121 patients were included, comprising 74 bone-origin sarcomas (72 osteosarcomas) and 47 soft tissue sarcomas; 77 patients were male and 44 were female. With a median follow-up of 21.7 months, postoperative ctDNA positivity was strongly associated with inferior survival. Median relapse-free survival was 6 months in ctDNA-positive patients versus 43 months in ctDNA-negative patients ($P < 0.001$). This prognostic separation remained significant across early ($\leq$1 month), intermediate (1–6 months), and late ($>$6 months) postoperative time windows. In multivariable Cox analysis, postoperative ctDNA status remained an independent prognostic factor (HR = 5.20, 95% CI: 2.07–13.08; $P < 0.001$). In 19 patients, ctDNA positivity preceded radiographic evidence of recurrence, with a mean lead time of approximately 3 months. Notably, 56 patients with persistently negative postoperative ctDNA experienced no recurrence or metastasis during follow-up. **Conclusions:** Tumor-informed ctDNA-based MRD detection is applicable to a broad range of sarcoma subtypes and provides robust prognostic information following surgery. These findings support the role of ctDNA as an early biomarker for disease recurrence in sarcoma. Clinical trial information: ChiCTR2400083045. Research Sponsor: None.

Leveraging a hybrid tumor-informed and tumor-agnostic ctDNA assay for optimal ctDNA-MRD detection: A real-world study in Southeast Asia. First Author: Anh Nguyen, Medical Genetics Institute, Ho Chi Minh, Viet Nam

Background: While tumor-informed ctDNA assays are the gold standard for minimal residual disease (MRD) detection, their utility is frequently limited by suboptimal tissue quality and quantity. This study evaluated a hybrid strategy combining personalized tumor-informed mutations and a tumor-agnostic hotspot panel to improve ctDNA-MRD detection in a real-world patient cohort. **Methods:** We retrospectively analyzed 1015 blood samples of 577 patients diagnosed with stage I-IV lung (n=222), colorectal (n=172), and breast (n=143) cancers. The hybrid assay (K-4CARE, Gene Solutions) integrated patient-specific variants with a cancer-specific tumor-agnostic hotspot panel (K-4CARE, Gene Solutions). ctDNA status was correlated with clinical outcomes in 200 early-stage patients (median follow-up $>$6 months) and 59 metastatic-stage patients. **Results:** The hybrid approach significantly outperformed the tumor-informed method, increasing pre-treatment ctDNA detection rates by 33.3–48.8% in cases with suboptimal tissue quality. In the early stage, post-operative ctDNA was detected in 93.5% (29/31) of the patients having recurrence, with the median lead time of 8.4 months; while 97.6% (165/169) of those with no recurrence had negative results. ctDNA positivity was an independent prognostic factor ($p<0.001$) that increased recurrence risk in lung (HR=145.4; 95% CI: 37.4-564.5), colorectal (HR=173.6; 95% CI: 19.7-$>$300.0), and breast (HR=147.8; 95% CI: 26.3-$>$500.0) cancers. In the metastatic stage, at 12 weeks after therapy initiation, 85.3% (29/34) of the molecular responders, who had ctDNA cleared or reduced by $>$50% of baseline VAF level, achieved clinical partial response or stable disease; while 88.0% (22/25) of the molecular non-responders had confirmed progressive disease. Notably, the tumor-agnostic hotspot panel helped identify new and resistance mutations, including EGFR T790M in lung (20.0%), ESR1 Y537N (7.1%), ESR1 Y538G (3.6%), ESR1 P535H (1.8%) in breast (12.5%), and KRAS G12D in colorectal (25.0%) cancers. **Conclusions:** This hybrid approach improved sensitivity to detect ctDNA-MRD, and the capability to identify emergent resistance mutations provides expanded clinical utility for longitudinal monitoring. Research Sponsor: Gene Solutions JSC, Ho Chi Minh city, Vietnam.

Cell-free DNA fragmentomics as an enabler of tumor-of-origin classification using a commercial targeted cfDNA panel. First Author: Kyle Helzer, Department of Human Oncology, University of Wisconsin-Madison, Madison, WI

Background: Analysis of cell-free DNA (cfDNA) fragmentation patterns ("fragmentomics") has emerged as a powerful approach for cancer detection and classification, but most prior studies rely on whole-genome or research-grade sequencing. The feasibility and performance of fragmentomics using commercial targeted cfDNA next-generation sequencing (NGS) panels used in routine clinical care remain unclear. We evaluated whether fragmentomics metrics derived from the Tempus xF targeted cancer exon panel could accurately classify tumor type. **Methods:** We analyzed cfDNA sequencing data from 1,950 patients across 10 cancer types sequenced on the Tempus xF clinical NGS panel (105 genes), split a priori into training (n=1,455) and validation (n=495) cohorts. Exon-level fragmentomics features were extracted, including fragment size distributions, Shannon entropy, normalized read depth, proportions of short fragments, fragment size bins, motif diversity, and chromatin-context–specific entropy metrics. Elastic-net regression models were trained to classify tumor type using 10-fold cross-validation, with area under the receiver-operating characteristic curve (AUROC) as the primary endpoint. Model performance was independently evaluated in the validation cohort, including stratification by circulating tumor DNA (ctDNA) fraction. **Results:** In cross-validation of the training cohort, a combined fragmentomics model achieved a median AUROC of 0.790 across cancer types. In independent validation, the combined model maintained robust performance with a median AUROC of 0.794. Prostate, breast, and ovarian cancers demonstrated the highest discrimination (validation AUROCs up to 0.952 and 0.936 for prostate and breast cancer, respectively). Performance improved substantially in samples with higher tumor burden: among validation samples with ctDNA fraction $\geq$10% (85.2% of cases), the median AUROC increased to 0.815 compared with 0.719 in low ctDNA samples. **Conclusions:** Fragmentomics analysis applied to an existing commercial targeted cfDNA panel enables accurate tumor-of-origin classification without additional sequencing or assays. These findings demonstrate a scalable strategy to extend the diagnostic capabilities of routine clinical cfDNA testing and support the integration of fragmentomics into real-world liquid biopsy workflows, particularly in patients with sufficient ctDNA fraction. Research Sponsor: None.

Ultrasensitive tumor-informed ctDNA MRD detection to identify metastatic relapse and as predictor of recurrence-free survival following resection of early-stage NSCLC. First Author: Fernando Pikabea Díaz, Division of Medical Oncology, Princess Margaret Cancer Centre/University Health Network, Toronto, ON, Canada

Background: After curative-intent resection of non-small cell lung cancer (NSCLC), patients remain at risk for metastatic relapse and development of second primary malignancies. Circulating tumor DNA (ctDNA) molecular residual disease (MRD) detection has prognostic value, but sensitivity in early-stage disease has been limited. We evaluated an ultrasensitive tumor-informed whole-genome sequencing (WGS) assay that leverages phased variants (PVs) for longitudinal MRD detection in a cohort from the ctDNA Lung DETECT study (NCT05254782). **Methods:** Patients with clinical stage I NSCLC treated with upfront surgery were enrolled at Princess Margaret Cancer Centre/University Health Network. Resected tumor tissue underwent WGS to generate personalized tumor-informed assays tracking up to 5000 somatic variants, including prioritized PVs prioritized (CLARITY, Foresight Diagnostics). Plasma samples (pre-operative, 3-6 weeks post-operative landmark, 6 months, 12 months, and at recurrence) were analyzed retrospectively with labs blinded to outcomes. Endpoints were MRD detection, recurrence free survival (RFS), MRD clearance patterns. **Results:** Of 128 clinical stage I patients with banked samples, 121 (95%) had sufficient tumor for WGS. Pathologic stage distribution AJCC 8th Ed. was stage 0/I/II/III/IV (n=1/86/22/1). Among 121 patients, 16 (13%) experienced distant recurrence and 15 (12%) developed second primary malignancies: lung, breast, ovarian, prostate and sarcoma. MRD detection at pre-operative (HR 5.6, p=0.002) and post-operative landmark (HR 4.2, p=0.002) was significantly associated with RFS. MRD+ at 12 months post-resection demonstrated stronger prognostic value, as 97% (91/94) MRD-negative patients remained recurrence free compared to 15% (2/13) MRD+ patients (HR 48.3, $p<0.0001$). We assessed MRD clearance between post-op landmark and later samples in patients who received adjuvant therapy. In total, 34 received adjuvant therapy; of these, 10 were MRD+ post-operatively with at least 1 subsequent sample. MRD clearance during or after adjuvant therapy was significantly associated with improved RFS (p=0.019). Patients with MRD clearance at any time after adjuvant therapy had 0% recurrence (0/4), while 83% (5/6) patients who failed to clear MRD despite adjuvant therapy had recurrence. In recurrence, MRD was detected in 94% (15/16) prior to or at recurrence. Only 1 MRD-negative patient recurred, $>$2 years after the last assessed sample. **Conclusions:** Ultrasensitive tumor-informed ctDNA MRD detection identifies patients at high risk for metastatic relapse following NSCLC resection, including pathologic Stage I, and may provide substantial lead time over conventional imaging. Clearance of post-surgical MRD with adjuvant therapy may inform post-resection surveillance and future studies of adjuvant therapy. Clinical trial information: NCT05254782. Research Sponsor: Princess Margaret Cancer Foundation; Ontario Institute for Cancer Research.

cfDNA sequencing as a cutting-edge technology to identify pathogenic germline variants from 8353 patients with advanced tumors at the Gustave Roussy Institute. First Author: Hela Sassi, Medical Biology and Pathology Department, Paris-Saclay University, Gustave Roussy, Villejuif, France

Background: Large cfDNA panels used for somatic profiling can incidentally reveal pathogenic variants of potential germline origin, with implications for patient management and hereditary cancer risk assessment. **Methods:** Between December 18th, 2020 and July 22nd, 2025, a weekly molecular tumor board reviewed cfDNA sequencing data from 8353 patients with advanced solid tumors treated at Gustave Roussy using the FoundationOne Liquid CDx panel, within the prospective STING trial (NCT04932525). We evaluated the yield, clinical relevance, and confirmatory outcomes of an MTB-governed workflow to flag putative germline pathogenic variants (PGPVs) from routine cfDNA profiling in advanced cancers. Across the 324 covered genes, we selected a list of 31 known hereditary cancer genes and 7 emerging candidates. Patients without prior germline confirmation were referred for genetic counseling and confirmatory testing on an independent sample. Turnaround times were compared with the conventional germline pathway. **Results:** Among 8,353 patients (mean age 62 years), 445 (5.3%) carried 471 PGPVs, including 23 patients with more than 2 variants. The most frequently implicated genes were *BRCA2* (n=101), *MUTYH* (n=81) and *BRCA1* (n=62). Overall, 54.6% of PGPVs were incidental findings (257/471); among incidental findings, 51.0% were clinically actionable (131/257), corresponding to 27.8% of all PGPVs (131/471). Germline status was confirmed in 172 patients (86 known prior to cfDNA profiling and 86 confirmed following cfDNA-guided referrals, including 60 incidental findings of which 52 were actionable; 14 variants (11 patients) were not confirmed and 6 were pending. For variants first flagged through cfDNA, the mean interval from liquid biopsy prescription to confirmatory germline report was 2 months, compared with 6 months through the conventional pathway. In evaluable paired cases, cfDNA showed high diagnostic performance for identifying germline findings (sensitivity 98.3%, specificity 97.4%). **Conclusions:** In an advanced pan-cancer real-world cohort, an MTB-governed cfDNA workflow identified PGPVs in 5% of patients, with over half representing incidental findings and 28% of all PGPVs being actionable. cfDNA profiling can accelerate referral and confirmation of hereditary cancer risk when coupled with expert interpretation and confirmatory germline testing, while acknowledging limitations for certain alterations. Research Sponsor: None.

***ESR1* mutation longitudinal dynamics in RWD cohort of HR+/HER2− metastatic breast cancer patients treated with standard-of-care hormonal therapy.** First Author: Malvika Pillai, Tempus AI, Chicago, IL

Background: *ESR1* mutations (*ESR1*m) are known drivers of resistance to aromatase inhibitors. While *ESR1*m has been linked to worse survival outcomes, clonal complexity over time has not been well-evaluated in a real-world context. Here we characterized longitudinal dynamics of *ESR1*m, including rare point mutation emergence and polyclonality in hormone receptor-positive/HER2-negative metastatic breast cancer (HR+/HER2- mBC) patients (pts) treated with aromatase inhibitor (AI) plus CDK4/6 inhibitor (CDK4/6i). **Methods:** We identified a cohort for longitudinal analysis from the Tempus real-world database (RWD). Eligible pts had HR+/HER2- mBC (diagnosed before 01/2023), received AI+CDK4/6i therapy in mBC, and had comprehensive genomic profiling from tissue/liquid biopsy (Tempus xT/Tempus xF) within 2 yrs of treatment, with ≥1 on-treatment xF tests. We analyzed *ESR1* clonal dynamics, starting from first *ESR1*m detection in a subset of pts who had multiple xF tests. Polyclonality was also assessed, defined as presence of at least 2 distinct *ESR1*m in a sample. **Results:** Of 301 HR+/HER2- mBC pts on AI+CDK4/6i therapy, 102 (33.9%) developed an *ESR1*m. In the *ESR1*m group, 72 pts (70.6%) had 2+ on-treatment liquid biopsies (Tempus xF/xF+), comprising the final cohort for observation. At *ESR1*m detection, 64.8% pts had a single detectable *ESR1*m, most commonly D538G (31.9%) and Y537S (12.5%). In contrast, 34.7% had polyclonal mutations (19.7% with 2 distinct mutations; 15.3% with 3+). Recurrent detection of D538G (52.8%), Y537S (20.8%), and Y537N (16.7%) was noted in repeat xF testing. Detection of additional *ESR1*m (26.4%) over time confirmed known common mutations such as Y537N (8.3%), D538G (5.6%), and Y537S (5.6%). However, longitudinal testing also found rare mutations such as V422del and H524L. Mutational dynamics shifts were also revealed by longitudinal testing. In 36.1% pts, a previously detected *ESR1*m was no longer found, often in those who initiated a SERD. D538G (5.6%) and Y537N (4.2%) were the most commonly lost mutations. Recurrent and new *ESR1*m detection occurred in pts who continued AI+CDK4/6i (44.4%). Many pts showed a combination of these dynamics. **Conclusions:** Multimodal RWD analyses demonstrate valuable clinical insights on *ESR1*m patterns detected from longitudinal molecular surveillance testing in HR+/HER2- mBC pts treated with AI+CDK4/6i. We observed shifting dynamics in *ESR1*m burden, including detection of rare mutations and polyclonality. These findings show the value of monitoring *ESR1*m longitudinally over disease course and prompt further research into clinical impacts of clonal dynamics. Research Sponsor: None.

Quantitative assessment of tumor shedding using AI-derived radiographic tumor burden and quantified liquid biopsy in advanced gastrointestinal cancers. First Author: Abdul Qahar K. Yasinzai, University of Florida/UF Health Cancer Institute, Gainesville, FL

Background: Radiographic imaging remains the clinical standard for assessing cancer treatment response; however, it lacks sensitivity to detect early biological shifts and spatially heterogeneous tumor behavior. Methylated circulating tumor DNA (mctDNA) provides a complementary molecular measure of disease burden, yet the quantitative relationship between radiographic tumor burden and DNA shedding remains poorly characterized. In this cohort study, we evaluated whether early changes in shed rate predict progression-free survival (PFS) and overall survival (OS) in patients with advanced gastrointestinal (GI) cancers. **Methods:** Patients with advanced GI malignancies receiving systemic therapies underwent paired longitudinal radiographic and liquid biopsy assessments. Radiographic tumor burden was quantified (OSCAR AI platform). Tumor contours were independently blinded reviewed by two radiologists. Up to 15 target lesions per organ were selected, and the total tumor burden was calculated analogous to longitudinal RECIST assessment. Tumor Methylation Score (TMS) from the Northstar Response assay quantified mctDNA. Tumor shed rate (TSR) was defined as the ratio of TMS to the AI-derived radiographic tumor volume and calculated at baseline and at the first on-treatment landmark using the closest-paired CT scan and blood drawn within 120 days. Fold-change in TSR from baseline was compared with PFS and OS. Undetectable tumor volume cases were excluded. **Results:** Forty patients were evaluable, with both baseline and landmark timepoints available within the 120-day window. TSR ranged from a min of 0 methylated molecules per mm^3 (m4) to a max of 1.0 m4 with a median of 0.06 m4. TSR significantly differed between tumor types (p=0.013, ANOVA), with CRC having the highest median shed rate (0.13 m4) and EGA and pancreatic having the lowest median shed rates (0 m4). TMS was significantly associated with tumor volume at baseline (Rsq=0.15,p=0.01, Deming) and on-treatment (Rsq=0.6, p<0.001, Deming). An increased TSR was associated with OS (HR=5.8, 95% CI 1.7-19.2, <0.01) and PFS (HR=3.5, 1.4-8.6, <0.01). **Conclusions:** TSR represents a novel, multidimensional integration of AI-driven volumetrics and liquid biopsy. Our findings suggest that an increasing shed rate is a predictor of PFS and OS, potentially serving as a lead-time indicator of tumor-host homeostatic decompensation. Future analysis will determine if TSR captures critical transitions in tumor biology that precede and perhaps drive radiographically detectable progression. Breast cancer screening is heating up: A novel thermophysics-based AI modality for screening subjects with BIRADS 4 or 5 mammograms. First Author: Nedal Darwish, Rochester General Health System, Rochester, NY

Background: Although mammography is an effective cancer detection modality, limited specificity at population scale leads to unnecessary biopsies, highlighting a need for adjunctive approaches. Cancer exhibits increased metabolic activity, leading to temperature differentials when compared with benign tissue. In this study, ultra-high sensitivity infrared imaging (IRI) was utilized with a novel thermophysics-based AI neural network to leverage temperature differentials for cancer screening. **Methods:** This prospective validation pilot study enrolled 14 patients with BI-RADS 4 or 5 breast lesions on diagnostic imaging prior to biopsy. IRI and optical images were acquired using an infrared imaging device at angular intervals, encoding the breast surface. Thermal and optical data were processed using a 3D reconstruction algorithm to generate breast surface thermal-spatial point-clouds, encoding temperature values at corresponding locations. Tumor presence or absence was predicted using an AI physics-informed neural network (PINN) that solves inverse bioheat transfer equations to identify heat sources associated with increased metabolic activity and blood perfusion. The PINN result was then compared to diagnostic mammography and to histologic findings on pathology. **Results:** 14 patients aged 42-83 years were included in a prespecified salient interim analysis approved by the study committee to assess feasibility. Histologic outcomes ranging from normal breast tissue to benign and premalignant/malignant conditions as outlined in Table 1. The PINN accurately predicted the presence and location of all premalignant/malignant lesions, including all incidences of IDC (n=3), DCIS (n=3), and ADH (n=2). Histologically benign lesions (n=6) were not detected by the PINN as a heat source. The mean size error for the PINN was 1.3 cm compared to size on pathology. **Conclusions:** Infrared imaging combined with a thermophysics-based AI neural network was able to localize and detect premalignant/malignant breast lesions with 100% sensitivity and specificity. Our findings suggest that IRI adjunctive screening may have the potential to both accurately detect breast cancer and minimize unnecessary biopsies. Research Sponsor: None.

Comparison of PINN assessment with histological outcome.

Number of Patients	Breast Tissue Type	PINN Assessment	PINN Diameter (cm)	Histologic Assessment	Histologic Diameter (cm)
2	SF	+	1.2, 2.2	ADH	2.1,3.0
3	SF	+	1.1, 1.4, 1.4	DCIS	2.1, 2.0, 2.8
3	SF	+	1.0, 1.2, 1.6	IDC	0.5, 3.0, 5.0
1	SF	–		Fibrosis	
1	SF	–		Cystic Fluid	
1	SF	–		Fibrocystic	
1	SF	–		Fibroadenoma	
1	SF	–		Duct Ectasia	
1	HD	–		Normal Breast	

Breast tissue density classifications: scattered fibro-glandular (SF), heterogeneously dense (HD). Histology subtypes: invasive ductal carcinoma (IDC), ductal carcinoma in situ (DCIS), atypical ductal hyperplasia (ADH). PINN=physics-informed neural network.

^{68}Ga-NODAGA-SNA014 whole-body PET imaging to detect Claudin18.2–positive pancreatic cancer lesions. First Author: Jihui Hao, Department of Pancreatic Cancer, Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin Medical University, Tianjin, China

Background: ^{68}Ga-labeled nanobody (^{68}Ga-NODAGA-SNA014) is a PET radiotracer based on a single-domain antibody. We conducted a first-in-human (FIH) evaluation of ^{68}Ga-NODAGA-SNA014 to characterize in vivo biodistribution, metabolism, radiation dosimetry, and safety, and to explore its ability to noninvasively quantify Claudin-18.2 (CLDN18.2) expression in patients with gastrointestinal cancers. **Methods:** ^{68}Ga-NODAGA-SNA014 was synthesized and first assessed preclinically in human pancreatic cancer cell lines and xenograft mouse models to evaluate affinity, specificity, and pharmacokinetics. We then performed a translational pilot study in 15 patients with pancreatic cancer imaged on a total-body (panoramic) PET/CT system. Whole-body biodistribution, organ dosimetry, and the association between lesion uptake and CLDN18.2 expression were analyzed and compared with ^{18}F-FDG, where available. **Results:** ^{68}Ga-NODAGA-SNA014 was produced reliably with favorable radiochemical characteristics. In preclinical studies, the tracer exhibited rapid blood clearance, high affinity for CLDN18.2, and specific uptake in CLDN18.2-positive cells and xenografts. In patients, physiologic uptake was highest in the stomach and kidneys, with mild uptake in the pancreas. Lesion uptake varied by CLDN18.2 expression level, and ^{68}Ga-NODAGA-SNA014 demonstrated more precise differentiation of CLDN18.2-high versus CLDN18.2-low lesions than ^{18}F-FDG. **Conclusions:** PET uptake (SUV) of ^{68}Ga-NODAGA-SNA014 correlated with CLDN18.2 expression, supporting its potential as a noninvasive companion diagnostic to guide and optimize CLDN18.2-targeted therapies. Comprehensive profiling and clinical utility of CSF-derived cell-free DNA/RNA for evaluation of solid and hematologic malignancies affecting the central nervous system. First Author: Ryan Gimple, Washington University in Saint Louis School of Medicine, St. Louis, MO

Background: Diagnosis and risk stratification of brain lesions is challenging when tissue biopsy is contraindicated due to anatomic or clinical factors. Cerebrospinal fluid (CSF)–based liquid biopsy using cell-free DNA (cfDNA) and RNA (cfRNA) offers a minimally invasive approach to detect neoplastic disease and inform management. We evaluated the clinical utility of a commercially available cfDNA/cfRNA next-generation sequencing assay applied to CSF specimens from patients with CNS lesions of uncertain etiology. **Methods:** Between 2023 and 2025, cfDNA, cfRNA, and CSF cell pellet RNA profiling using next generation sequencing (NGS) was performed on CSF samples from 1,559 patients, including 1,209 evaluated for suspected primary or secondary solid CNS malignancies and 350 evaluated for CNS involvement by hematologic malignancies. The assay interrogated single-nucleotide variants, insertions/deletions, copy number alterations, gene fusions, lymphocyte clonality, and tumor mutational burden. The depth of sequencing was between 25,000x and 30,000x for cfDNA. For quality control purposes, more than 80 million reads were required for accepting RNA results, while the required percentage of spliced RNA reads was above 20%. Clinical utility and actionability was further assessed in a single-institution cohort of 90 patients by correlating cfDNA/cfRNA results with cytology, flow cytometry, tissue biopsy, and clinical decision-making. **Results:** Among patients evaluated for solid malignancies in the entire cohort, the most common alterations involved TP53, KMT2C, PIK3CA, EGFR, and DNMT3A, while hematologic cases frequently harbored PIM1, TP53, MYD88, CD79B, TET2, and DNMT3A alterations. In the institutional cohort (median age 57 years), neoplastic cfDNA was detected in 40/90 samples, with recurrent alterations mirroring those of the larger panel. cfDNA profiling demonstrated 100% sensitivity for neoplastic DNA detection compared with current standard-of-care cytology and flow cytometry and identified neoplastic DNA in 37% of cytology-negative and 42% of flow-negative cases. Concordance with contemporaneous tissue biopsy yielded a positive predictive value of 89%, with a sensitivity of 68%, reflecting reduced detection in intraparenchymal lesions with limited CSF exposure. cfDNA results directly influenced treatment decisions in patients evaluated for new intracranial malignancy and for CNS metastasis or recurrence. **Conclusions:** CSF cfDNA/cfRNA profiling significantly enhanced diagnostic yield in CNS lesions of uncertain etiology, particularly when conventional cytology is negative, or biopsy is infeasible, while also providing actionable molecular information to guide therapy. Application of long-read sequencing to resolve cryptic genomic instability across cancer types. First Author: Josh Vo, Michigan Center for Translational Pathology, Department of Pathology, University of Michigan, Ann Arbor, MI

Background: Computational mutational signatures can identify tumors with homologous recombination deficiency (HRD), mismatch repair deficiency (MMRD), and focal tandem duplication (FTD) phenotypes, nominating patients for PARP inhibitors or immune checkpoint blockade. However, many signature-positive cases lack identifiable causative alterations by conventional sequencing, forcing patients toward empiric therapy or clinical trial enrollment without molecular confirmation. We evaluated whether long-read nanopore sequencing could provide definitive molecular diagnoses to guide evidence-based treatment selection. **Methods:** We analyzed 768 patients with advanced prostate (n=505), breast (n=246), and ovarian (n=17) cancers enrolled in the MiOncoSeq precision oncology program. Computational signature analysis identified cases with HRD, MMRD, or FTD phenotypes. Cases unresolved by standard short-read sequencing underwent long-read nanopore sequencing with integrated structural variant detection, methylation profiling, and haplotype phasing. **Results:** Signature analysis identified 164 cases (21.3%) with genomic instability phenotypes. Short-read sequencing resolved 118/164 cases (71.9%), leaving 46 patients without molecular confirmation. Long-read sequencing achieved mechanistic resolution in 32/46 cases (69.6%), with complete resolution of MMRD (5/5, 100%) and FTD (7/7, 100%). Secondary signature analysis reclassified 11/14 unresolved HRD cases as non-classical, likely reflecting alternative DNA repair defects or replication stress, refining diagnostic yield to 86.9% (20/23) for credible HRD. Cryptic mechanisms included promoter hypermethylation (*BRCA1*, *MLH1*, *RAD51C*), balanced structural rearrangements (*CDK12*, *PMS2*), and deep intronic splice variants (*PALB2, BARD1*). Long-read sequencing also uncovered 3 previously undetected pathogenic germline variants (*BARD1*, *BRIP1*, *PALB2*) with direct implications for hereditary cancer risk assessment and family screening. Combined analysis identified actionable findings enabling targeted therapy selection in 19.5% of patients. **Conclusions:** Long-read sequencing provides definitive molecular diagnoses for patients with signature-positive tumors, enables evidence-based therapy selection over empiric treatment, and uncovers cryptic germline variants informing hereditary cancer risk. Research Sponsor: National Cancer Institute.

CLERAD-PROBE: Dosimetric analysis of I-124 PET–guided remnant radioiodine ablation in differentiated thyroid carcinoma. First Author: Kerstin Michalski, Department of Nuclear Medicine, University Hospital Wuerzburg, Wuerzburg, Germany

Background: The role of adjuvant radioiodine therapy (RIT) in differentiated thyroid carcinoma (DTC) remains controversial due to a lack of long-term data from randomized controlled trials. Consequently, international guidelines diverge; while some advocate broad application, others prioritize a restrictive, risk-adapted approach. The CLERAD-PROBE trial aims to bridge this gap by comparing both strategies regarding blood dose — as an established surrogate for secondary malignancy risk — and oncological outcomes. **Methods:** CLERAD-PROBE is a prospective, randomized, bicentric study (NCT01704586) in adult DTC patients, excluding those with unifocal papillary microcarcinomas $\leq$ 10 mm limited to the thyroid. Following thyroidectomy, patients in Arm 1 underwent I-124 PET for staging and dosimetry. Adjuvant RIT was administered if one or multiple of the following risk factors were present: incomplete surgical resection, tumor size $>$4cm or extrathyroidal extent, lymph node metastases and age $\geq$ 45 years, distant metastases, and/or iodine-avid lesions on I-124 PET. In Arm 2, adjuvant RIT was generally performed. Follow-up was performed every 4–6 months using thyroglobulin measurements and cervical ultrasound. The primary endpoint was the mean blood dose after complete remission or 18 months. Secondary endpoints included progression- and recurrence-free survival at 3 and 10 years. **Results:** The primary endpoint was evaluable in 315 patients, enrolled from May 2015 to May 2021 (148 in Arm 1, 167 in Arm 2). Study arms were matched with regards to histology, age, and tumor/nodal stage, though Arm 1 had significantly fewer men (22% vs. 34%, p = 0.02). I-124 PET identified lymph node metastases in 49 patients and distant metastases in 13 patients. RIT was performed in 68 of 148 (46%) patients in Arm 1. Of these, 13 patients with low-risk carcinoma underwent RIT because of new metastases found on I-124 PET. The mean absorbed blood doses (252 mGy vs 447 mGy, range: 4 - 3217 mGy vs. 48 - 2520 mGy; $p < 0.001$) and administered I-131-activities (2.3 GBq vs. 4.9 GBq; range: 0 – 18.6 GBq vs. 1.0 – 26.2 GBq; $p < 0.001$) were lower in Arm 1. **Conclusions:** I-124 PET identifies persistent, iodine-avid disease in patients who would not routinely receive adjuvant RIT pursuant to ATA Guidelines, while enabling individualized selection in the others to minimize secondary malignancy risk. The impact on long term oncological outcomes has yet to be determined. Three years follow-up analyses evaluating recurrence rates and overall oncological safety are currently in progress and will be presented at the congress. Clinical trial information: NCT01704586. Research Sponsor: German Cancer Aid; 110751.

iPREDICT: Phase II study of CD8 PET in patients with immunoresponsive solid tumors—Imaging characteristics and correlation with RECIST response. First Author: Kim Allyson Margolin, Providence Saint John's Cancer Institute, Santa Monica, CA

Background: CD8 T cells mediate antitumor effects of immune checkpoint blockade (ICB); their histologically-determined abundance prior to or during therapy (Rx) appears to correlate with ICB response in melanoma (MEL) and other solid tumors. We performed this Phase IIb study to assess CD8 targeted PET imaging with ^{89}Zr-crefmirlimab berdoxam prior to and during ICB Rx to study its potential as a marker for Rx selection, enhancement or even replacement of existing tumor measurement systems, and correlation of clinical outcomes. **Methods:** 70 patients (pts) with MEL or Merkel cell cancer (MCC) (27), renal cell cancer (RCC) (35) or lung cancer (NSCLC) (8) who were eligible for first or second-line single- or double-agent ICB or ICB plus an oral kinase inhibitor (TKI) were enrolled. ^{89}Zr-crefmirlimab berdoxam (1 mCi,1.5 mg protein), was administered intravenously $\leq$2 weeks prior to cycle 1 of ICB Rx, followed by a PET/CT scan 24 (+/-3) hours later (baseline, BL). The 2nd tracer injection and associated PET/CT scan occurred 4-6 weeks after ICB Rx initiation, prior to cycle 3 (on treatment, OT). Standard of Care imaging and RECIST 1.1 were used to assess response to Rx. **Results:** All 70 pts were evaluable for safety analysis; none experienced an SAE related to imaging agent. 65 pts (21 MEL, 2 MCC, 34 RCC and 8 NSCLC) were included in the primary endpoint analysis of correlating CD8 PET scans with best confirmed overall response (BOR) by RECIST 1.1. MEL and MCC pts received single (6/23) or double ICB (17/23), RCC pts received single ICB with/without TKI (21/34) or dual ICB (13/34), and all NSLCL pts received single ICB. In the RCC cohort, multiple CD8 PET metrics showed statistically significant association with either individual BOR or Binary Response at BL, OT or as delta, including: Tumor Standard Uptake Value (SUV), Lymph Node (LN) SUV, relative percentage of CD8 negative or positive lesions and normal organ SUV. Normalization to reference organs improved the correlation with BOR for the combined cohorts and for the MEL/MCC cohort. Depending on clinical objectives, different classification rules to predict BOR were applied, prioritizing specificity for non-responders and sensitivity for responders (Table). These results were cohort-dependent, as each cohort exhibited a distinct distribution of SUVs. **Conclusions:** PET imaging can quantitate CD8 T cells with sufficient specificity and sensitivity to support further study in selection of pts for Rx regimens and assessing early response to therapy. Clinical trial information: NCT05013099. Research Sponsor: Imaginab.

Prediction of BOR by CD8 PET.

Cohort	Response	Parameter	Timepoint	AUC	95% CI	Sensitivity	Specificity

Cell-free DNA methylation profile–based fusion epigenotyping to enhance *ALK* fusion detection in NSCLC patients. First Author: Laura Tung, Guardant Health, Palo Alto, CA

Background: Short read lengths in next-generation sequencing and targeted panel probe design pose challenges to fusion detection by impairing the resolution of complex genomic rearrangements and the accurate mapping of intronic breakpoints. To address these limitations, we developed a cell-free DNA (cfDNA) methylation-based fusion epigenotyping method that leverages fusion-associated tumor epigenetic signatures to complement genomic-based methods and increase the fusion detection sensitivity of our liquid biopsy. We validated *EML4-ALK* fusion detection by this algorithm in non-small cell lung cancer (NSCLC) using paired clinical tumor tissue and cfDNA samples. **Methods:** We trained a binary classifier to discriminate *EML4-ALK* fusion-positive from fusion-negative NSCLC using cfDNA methylation signal and genomic molecule support. To validate the epigenotyping classifier, an independent cohort of 577 clinical NSCLC samples was selected with paired tumor tissue and Guardant360 Liquid (Guardant Health, Palo Alto, CA) cfDNA for each patient (with epigenomic tumor fraction $>$ 0.03%). The cohort included 94 tissue-confirmed fusion-positive samples (78 cfDNA genomic positives and 16 cfDNA genomic false negatives) with *EML4-ALK* detected in tumor tissue, and 483 tissue-confirmed fusion-negative samples (*ALK* fusion negative in both tissue and paired cfDNA). The epigenotyping classifier predictions in cfDNA were evaluated against tissue-based orthogonal truth. **Results:** Among tissue-confirmed fusion-positive samples, tissue-liquid assessment showed a high positive percent agreement (PPA) / sensitivity of 89.36% (84/94), as well as 100% concordance with genomic caller positives (78/78). The rate of rescued fusions by the epigenotyping classifier from genomic false negative liquid cases was 38% (6/16). Among tissue-confirmed fusion-negative samples, tissue-liquid assessment showed a high negative percent agreement (NPA) / specificity of 99.38% (480/483). The false positive rate (FPR) of high confidence calls (probability exceeding a 99.7% specificity threshold or with partial genomic evidence) was 0.0% (0/483). **Conclusions:** cfDNA methylation-based fusion epigenotyping substantially increased detection of actionable *ALK* fusions while maintaining high specificity, as demonstrated by tissue-liquid concordance. The results of this approach showed the clinical value of giving NSCLC patients an increased likelihood to receive more effective, less toxic ALK inhibitor therapy, while the minimized FPR helps ensure appropriately matched treatment decisions. Research Sponsor: Guardant Health.

Multicenter clinical study of [^{18}F]AlF-HER2-BCH PET/CT as a molecular pathology tool for linear quantification of HER2 expression levels in breast cancer. First Author: Xiaoyi Guo, NMPA Key Laboratory for Research and Evaluation of Radiopharmaceuticals, Department of Nuclear Medicine, Peking University Cancer Hospital & Institute, Beijing, Beijing, China

Background: Determining the human epidermal growth factor receptor 2 (HER2) status is essential in metastatic breast cancer (MBC) management. To establish the clinical validity of [^{18}F]AlF-HER2-BCH PET/CT (HER2-PET), we assessed the diagnostic accuracy of qualitative and quantitative HER2-PET assessment to predict HER2 expression by immunohistochemistry (IHC), including HER2-negative and -low breast cancer. **Methods:** This prospective multicenter trial enrolled treatment-naïve patients with newly diagnosed, non-rapidly progressive breast cancer across all molecular subtypes. Paired HER2 PET and [^{18}F]FDG PET/CT (FDG-PET) scans were acquired within a standardized 7-day. Tumor uptake was quantified using maximum standardized uptake value (SUVmax) and target-to-background ratios (TBR), and analyzed via general linear mixed models. **Results:** Between 2020 to June 2025, 240 patients were analyzed. Comparative analysis revealed superior diagnostic performance of whole-body HER2-PET versus FDG-PET for malignant lesion detection: sensitivity (97.6% vs 89.9%), specificity (83.9% vs 77.4%%), and overall accuracy (96.4% vs 88.9%). Quantitative HER2-PET analysis revealed significantly different SUVmax values across HER2 expression categories (median [IQR]: HER2-positive 13.1 [9.2-20.7] vs HER2-low 7.3 [5.1-8.9] vs HER2-negative 3.2 [2.7-4.5]; P$<$0.001), demonstrating strong correlation with IHC/FISH-defined HER2 status. In contrast, FDG-PET uptake showed no association with HER2 status (P=0.5). Among 10 discordant cases between HER2-PET and standard IHC/FISH: eight (80%) represented confirmed biological heterogeneity, with differing HER2 status across metastatic sites; two (20%) IHC 1+ cases exhibited PET-positive/FISH-amplified patterns, suggesting potential IHC false-negative results. **Conclusions:** [^{18}F]AlF-HER2-BCH PET/CT provides comprehensive HER2 profiling beyond single-biopsy IHC, offering new therapeutic insights for HER2-low/negative metastatic breast cancer through whole-body molecular visualization. Clinical trial information: NCT04547309. Research Sponsor: None.

Diagnostic performance of Al^{18}F-HER2-BCH PET/CT and ^{18}F-FDG PET/CT, in the detection of primary and metastatic lesions in the evaluable imaging core population (N participant=240, N Biopsy-proven lesion=359).

FAPI-CUP: A prospective cohort study of patients with cancer of unknown primary (CUP) to evaluate a novel radiotracer, fibroblast activated protein (FAPI), targeting cancer-associated fibroblasts for primary site detection. First Author: Tharani Sivakumaran, Department of Medical Oncology, Peter MacCallum Cancer Centre and Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, Australia

Background: Cancer of unknown primary (CUP) represents a heterogeneous group of metastatic tumours for which standardised diagnostic work-up fails to identify the site of origin at diagnosis. ^{18}F-FDG-PET/CT aids in identifying a putative primary site in ~30-50% of CUP patient (pts); however, has limited sensitivity for detecting cancers with high stromal content. Fibroblast activation protein (FAP) is a type II transmembrane serine protease and highly expressed by cancer-associated fibroblasts abundant in desmoplastic tumours such as CUP. ^{68}Ga-FAPI-46 is a FAP-targeting PET tracer but has not been directly compared to ^{18}F-FDG-PET/CT in CUP. Aims: We aimed to determine if the addition of ^{68}Ga-FAPI-46 detects more primary sites compared with ^{18}F-FDG-PET/CT and CT CAP (standard of care; SoC) in CUP pts and if there is an association between the level of FAPI avidity and response to systemic treatment. **Methods:** A prospective cohort study recruiting CUP pts across four sites in Australia. Key inclusion criteria: 1) pts considered CUP after diagnostic work-up, pathological review and gender appropriate tests; 2) adequate haematologic and organ function; 3) not commenced current line of systemic treatment (exception palliative radiotherapy for symptom control); 4) ECOG $\leq$ 2 and life expectancy $>$ 3months. 5) $\leq$1 prior line of systemic treatment. Pts undergo SoC imaging (CT CAP, ^{18}F-FDG-PET/CT) and ^{68}Ga-FAPI-46 PET/CT scan which are reviewed at a multidisciplinary meeting to determine primary site. Clinicopathological review and genomic analysis (if available) were used to determine final primary site. Pts start systemic treatment and have SoC follow-up with data regarding RECIST 1.1 response, survival outcome and further lines of treatment for 12 months. **Results:** At interim analysis 60 pts were recruited from 03/2022 to 06/2025. Median age was 68 years [30-83] with 89% being ECOG 0-1 and 80% classified as having an unfavourable CUP subtype. A primary site was detected in 37/60 (62%) and 33/60 (55%) pts with ^{68}Ga-FAPI-46 PET/CT and SoC and SoC alone, respectively. Cholangiocarcinoma (9/37; 24%) and lung (7/37; 19%) were the commonest primary sites detected. 46/60 (77%) pts commenced systemic treatment with a best overall response rate of 9/38 (24%) in RECIST evaluable pts. There was no association between RECIST response and baseline FAPI avidity for either average SUVmax top 3 lesions (p=0.653) or highest SUVmax (p=0.416). **Conclusions:** ^{68}Ga-FAPI-46 PET/CT in addition to SoC detected a primary site in more patients compared to SoC imaging alone. There was no association between RECIST response and baseline FAPI avidity. Clinical trial information: NCT05263700. Research Sponsor: MRFF.

Integrated imaging cytology profiling system for rapid point-of-care molecular diagnosis of leptomeningeal metastasis in breast cancer. First Author: Hyungsoon Im, Center for Systems Biology, Massachusetts General Hospital; Department of Radiology, Massachusetts General Hospital, Boston, MA

Background: Leptomeningeal metastasis (LM) from breast cancer has a poor prognosis (median survival ~4 months). Early and accurate diagnosis and phenotyping enable timely therapeutic intervention, particularly with emerging targeted agents such as antibody–drug conjugates (ADCs), to improve clinical outcomes. Yet, MRI and CSF cytology often lack sensitivity. We developed iSCOPE, an integrated imaging cytology platform that rapidly enriches and detects tumor cells in CSF via single-cell immunomolecular profiling. **Methods:** Breast cancer patients with neurological symptoms and/or suspicion for LM were enrolled in the study (IRB: KNUCH 2020-08-015). CSF (5–10 mL) was obtained by lumbar puncture for iSCOPE testing, and the rest was for conventional cytology examination. iSCOPE (integrated single-cell on-chip point-of-care evaluation) enriches large epithelial cells from unprocessed CSF at single-cell capture sites in a microfluidic chip while smaller blood cells pass through. Captured cells are then immunolabeled with QUAD markers (a four-marker combination overexpressed in breast cancer), as well as HER2 and ER/PR, for phenotyping. Automatic quantitative fluorescence imaging using a miniaturized imager reports the total cells, QUAD-positive cells, and their phenotypes in 1 hour. iSCOPE was validated using FNA cytology samples and then applied to CSF samples. Results were compared with conventional CSF cytology. **Results:** In the validation study using FNA cytology samples, iSCOPE demonstrated excellent breast cancer detection accuracy based on QUAD-positive cell counts (area under the curve/AUC = 0.995), and receptor phenotyping showed concordance with clinical pathology (AUC $>$ 0.9). In CSF testing, iSCOPE correctly discriminated between LM (n = 7) and control CSF samples from patients with normal pressure hydrocephalus (n = 5). In serially collected CSF testing due to inconclusive diagnoses, iSCOPE detected LM in two cases, a few months earlier than conventional cytology when a suspicious finding was initially made (Table 1). **Conclusions:** This study demonstrates the clinical feasibility of iSCOPE for CSF-based diagnosis of LM in breast cancer. iSCOPE addresses current challenges in cytology analysis by incorporating a microfluidic chip to enrich for scant, suspicious cells and by using immunomolecular profiling to detect tumor cells. The CSF study results highlight the potential clinical use of iSCOPE for detecting LM in a point-of-care setting. Research Sponsor: National Institute of General Medical Sciences (NIGMS); R01GM138778; National Cancer Institute; R33CA281794; Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI); HR - 2022 - KH130591.

Diagnostic performance, safety, and biodistribution of [^{68}Ga]Ga-OncoACP3 for PET imaging in prostate cancer: A phase I clinical trial. First Author: Cristiano Pini, Vita-Salute San Raffaele University, Milan, Italy

Background: Acid Phosphatase 3 (ACP3) is an emerging promising theranostic target in prostate cancer (PCa), expressed on PCa cells across most primary and metastatic lesions. ACP3 shows higher, more homogeneous expression than PSMA in low- and high-ISUP-grade tumours and in metastases, while not being expressed in healthy organs such as salivary glands, kidneys, and gastrointestinal tract. We present data from a multicentre, prospective phase I clinical trial investigating safety, dosimetry, pharmacokinetics, and diagnostic performance of [^{68}Ga]Ga-OncoACP3, a high-affinity ligand of ACP3 discovered from DNA-Encoded Chemical Libraries, in PCa. **Methods:** Twenty patients with a confirmed diagnosis of PCa were planned for enrolment in the study in two cohorts: Cohort A, 5 patients with primary tumour only; Cohort B, 15 patients with or without metastatic disease. Each patient received a single intravenous injection of [^{68}Ga]Ga-OncoACP3. PET/CT acquisitions were performed at 0, 10, 60 and 120 minutes after the injection with multiple blood and urine samples collections for pharmacokinetic and dosimetric analysis. Adverse events were recorded and graded according to CTCAE v5.0. [^{68}Ga]Ga-OncoACP3 PET findings were compared with PSMA PET (performed by all patients, according to clinical practice) and, when available, with follow-up data and histopathological findings. **Results:** All 20 patients completed [^{68}Ga]Ga-OncoACP3 PET imaging: 8 for initial staging, 10 for biochemical relapse, and 2 for advanced disease evaluation. No adverse events occurred. The tracer showed mixed hepatobiliary/renal excretion, with no uptake in salivary glands. PET-positive lesions showed rapid and selective tumour uptake shortly after injection, with increasing signal intensity at 60 and 120 minutes. All confirmed PSMA-positive lesions were evident at [^{68}Ga]Ga-OncoACP3 PET, in most cases with a higher tumour-to-background compared to PSMA PET. In three cases, [^{68}Ga]Ga-OncoACP3 PET detected additional PCa lesions, all confirmed by follow-up data or histopathology. No area of unspecific bone uptake at PSMA PET was evident at [^{68}Ga]Ga-OncoACP3. **Conclusions:** [^{68}Ga]Ga-OncoACP3 has an excellent safety profile and favourable pharmacokinetics, as well as promising tumour-targeting properties in PCa. [^{68}Ga]Ga-OncoACP3 may outperform current PSMA-targeting modalities across the whole natural history of the disease, and particularly in theranostic applications. Clinical trial information: NCT06840535. Research Sponsor: Philogen S.p.A.

Diagnostic performance, safety, and biodistribution of [^{68}Ga]Ga-OncoCAIX for PET/CT imaging: A first-in-human phase I clinical trial in clear cell renal cell carcinoma. First Author: Fabrizia Gelardi, IRCCS Ospedale San Raffaele, Milano, Italy

Background: Conventional imaging techniques are routinely used in clear cell renal cell carcinoma (ccRCC). However, their ability to accurately characterise tumour biology and stage the disease remains limited. An attractive target for theranostic applications is represented by carbonic anhydrase IX (CAIX), which is overexpressed in ccRCC. [^{68}Ga]Ga-OncoCAIX is a novel small-molecule radiopharmaceutical for positron emission tomography (PET) imaging. The compound has been discovered by DNA-Encoded Chemical Libraries and designed to selectively bind to CAIX, allowing for tumour-specific uptake and favourable biodistribution in preclinical models. This multicentre, prospective, phase I study provides the first-in-human assessment of [^{68}Ga]Ga-OncoCAIX PET/CT in patients with kidney lesions. **Methods:** Twenty patients with suspected primary or recurrent ccRCC based on conventional imaging were planned for enrolment in the study. Each patient received a single intravenous injection of [^{68}Ga]Ga-OncoCAIX. PET/CT acquisitions were performed at 0, 10, 60 and 120 minutes after the injection with multiple blood and urine samples collections for pharmacokinetic and dosimetric analysis. Adverse events were recorded and graded according to CTCAE v5.0. Where available, PET findings were correlated with histopathology. **Results:** Twenty patients were included. Seventeen patients were evaluated for incidentally detected renal masses, and three for suspected recurrence identified on CT or MRI. [^{68}Ga]Ga-OncoCAIX was well tolerated, with no drug-related AEs reported. The tracer demonstrated mixed renal and hepatic clearance, favourable biodistribution, and low background activity in healthy tissues, including the kidneys. Physiological uptake was mainly observed in the gastrointestinal tract, particularly the stomach. PET-positive lesions showed rapid and selective tumour uptake shortly after injection, with increasing signal intensity at 60 and 120 minutes. Eight patients had positive PET findings, eleven scans were negative and one patient presented a lesion with mild tracer uptake. Available histopathological confirmation showed concordance with PET results, including three PET-positive ccRCCs, three PET-negative oncocytomas, and one PET-negative chromophobe RCC; the one lesion with mild tracer uptake corresponded to a papillary RCC with mild CAIX expression on histology. Dosimetric analyses are ongoing. **Conclusions:** [^{68}Ga]Ga-OncoCAIX shows an excellent safety profile and favourable biodistribution, as well as promising tumour-targeting properties in ccRCC lesions. These preliminary findings support its potential role for the detection and characterisation of ccRCC. Complete data on histopathology will confirm the diagnostic accuracy and potential clinical utility in patients with suspected ccRCC. Clinical trial information: NCT06840548. Research Sponsor: Philogen S.p.a.

Molecular characteristics and outcomes of a real-world cohort of carcinoma of unknown primary determined by tissue-of-origin assays. First Author: Nisha Ramamurthy, George Washington University School of Medicine and Health Sciences, Washington, DC

Background: Carcinoma of unknown primary (CUP) increasingly intersects with precision oncology as molecular profiling becomes integrated into diagnostic algorithms. However, published CUP cohorts and guideline-based series remain anchored to clinical and pathologic criteria and do not characterize patients whose tissue-of-origin (TOO) predictions remain low probability despite comprehensive molecular analysis. This population—where molecular data fail to resolve lineage—is poorly described. We evaluated clinical, molecular, and outcome features of CUP defined as $<$ 90% probability for all predicted lineages. **Methods:** A retrospective chart review of TOO tests ordered at a single academic center between 2021-2025 was conducted. Demographics, pathology, molecular features including Tumor Mutational Burden (TMB), mutational profiles, predicted lineages, and treatments were abstracted from the TOO report and electronic health record. Survival status was assessed as of 12/31/2025. **Results:** Among 132 patients evaluated for CUP, 50 met the study definition (TOO probability $<$90% for a single lineage). Median age was 66 years, 56% were female and 76% were Black. Predicted lineages spanned gastrointestinal, pancreaticobiliary, lung, breast, melanoma, and genitourinary tissues, reflecting heterogeneity and lack of dominant lineage signal. Many tumors demonstrated overlapping immunophenotypes consistent with molecular ambiguity. High TMB ($\geq$10 mut/Mb) was reported in 16% with PD-L1 positive in 4%, limiting eligibility for tissue-agnostic immunotherapy. Most patients received empiric systemic therapy rather than site-directed or molecularly targeted regimens. Targetable alterations reported included BRAF, KRAS, HER2, ATM, CHEK2, and PIK3CA. TOO primary site predictions were in concordance with final pathology in only 22 cases (44%). At last follow-up, 29 patients (57%) were deceased. **Conclusions:** This study characterizes a precision-oncology–relevant subset of CUP in which molecular classifiers fail to assign high-confidence lineage, a population not represented in prior CUP publications. Tumors in this cohort showed broad predicted lineages across multiple organ systems with low rates of high TMB, reflecting substantial molecular heterogeneity. Many displayed nondistinct histology with overlapping immunophenotypes, consistent with diagnostic ambiguity. Concordance between predicted TOO and final pathology was limited, underscoring the challenges of relying solely on molecular classifiers. Actionable targets and markers for immunotherapy were infrequent, and most patients received empiric chemotherapy. Outcomes were poor, underscoring the unmet need for improved integrative molecular approaches and novel precision-oncology strategies in CUP subsets that remain unresolved despite comprehensive molecular assessment. Research Sponsor: None.

Analytical validation of a plasma-based cfDNA NGS assay (Guardant360 Liquid CDx) for comprehensive solid tumor profiling. First Author: Brett Kennedy, Guardant Health, Palo Alto, CA

Background: NGS-based profiling of circulating cell-free DNA (cfDNA) enables accurate and sensitive tumor genotyping from blood. Guardant360 Liquid CDx is intended as a companion diagnostic for comprehensive tumor mutation profiling across $>$700 genes in patients with malignant neoplasms. Analytical performance was evaluated per FDA IVD standards and guidelines across five variant classes: single-nucleotide variants (SNVs), insertions/deletions (indels), gene rearrangements, gene amplifications (CNA), and copy-number losses (CNLs) – with emphasis on accuracy, precision, specificity (limit of blank [LoB]), and limit of detection (LoD). **Methods:** Analytical Validation tested $>$4000 samples from nearly 2,000 unique patients across 29 cancer types, as well as contrived materials. Concordance was evaluated against FDA-approved Guardant360 CDx and an externally developed ctDNA assay, where applicable. Primary endpoints were positive percent agreement (PPA) and negative percent agreement (NPA) by variant class and category (clinically significant vs panel-wide). LoD was established at both low and high input levels. No minimum cfDNA ng input cutoff was required; low-input performance was evaluated at minimum molecule coverage (QC threshold). Precision was assessed across workflow components and blood collection tube (BCT) lots. Specificity was assessed using healthy donor cfDNA sequenced with multiple replicates at high input. **Results:** Clinical samples demonstrated a high QC pass rate of 99.1%. Clinically significant variants showed high concordance: SNV PPA 94.9% with NPA 99.86%, and indel PPA 96.24% with NPA 99.98%. Panel-wide specificity was near-perfect (SNV NPA 99.99966%; indel NPA 99.99991%). Rearrangements achieved PPA 94.64% and NPA 99.76%; CNA PPA 91.67% and NPA 99.97% ; CNL PPA 100% and NPA 97.56%. High-input LoD was established in silico and confirmed with clinical samples: 0.2% mutant allele frequency (MAF) for all clinically relevant SNVs, indels and most rearrangements, with selected variant LoD as low as 0.1% (KRAS G12C). At the minimum input, panel-wide LoD was 1.0% for clinically relevant SNVs and 0.9% for indels; 0.5-1.6% for rearrangements, 2.3-2.4 copies for CNAs, and 22.7% tumor fraction for CNL. Precision studies showed $\geq$98.6% agreement across conditions at near-LoD variant levels; within-lot and between-lot BCT precision yielded $>$97% analytical positive/negative agreement (targeted variants $\geq 1\times$ LoD). In LoB, no false positive variants were detected in any healthy donor replicates (0% FPR per sample and per variant), validating in-silico CHIP detection methods. **Conclusions:** The assay demonstrates high accuracy, precision and specificity across all reportable variant classes, with LoD at or below 0.2% MAF for key variant types. These data support its use for comprehensive, pan-cancer tumor genomic profiling in routine oncology practice. Research Sponsor: None.

3078 Poster Session

Farnesyl transferase inhibitor (FTI) darlifarnib (KO-2806) in combination with adagrasib in *KRAS* G12C mutated (mut) advanced solid tumors: Preliminary results from the FIT-001 phase 1 first-in-human trial. First Author: Andrea Zivi, Centro Ricerche Cliniche di Verona, Verona, Italy

Background: Clinical response to RAS inhibitors (RASi) is often limited by inherent/adaptive resistance mediated by persistent mTORC1 signaling. RHEB is a farnesylation-dependent protein required for mTORC1 activation. Darlifarnib, a potent next-generation FTI, selectively inhibits mTORC1 pathway activation and demonstrates synergistic antitumor activity in combination with the KRAS G12C inhibitor adagrasib (ada) in preclinical models, supporting potential to improve clinical activity in *KRAS* G12C mut tumors. **Methods:** FIT-001 (NCT06026410) is an ongoing, multicenter, open-label Ph1 dose escalation/expansion study of darlifarnib in advanced solid tumors. Darlifarnib 3, 5 or 8 mg QD D1–7, D15–21 + ada 400 mg BID in 28d cycles was evaluated in heavily pretreated pts with *KRAS* G12C mut NSCLC, PDAC or CRC. Primary objectives: safety/tolerability; key secondary objective: antitumor activity. **Results:** Dose escalation resulted in candidate darlifarnib doses of 3 and 5 mg. As of 15 Dec 2025, 30 pts (median age 61y; 63% male; 83% White; 93% baseline [BL] Karnofsky performance status 80–100%) received ≥1 darlifarnib 3 (n=15) or 5 mg (n=15) + ada dose. Primary tumor types: 30% NSCLC, 20% PDAC, 50% CRC. Pts were heavily pretreated: 43% had ≥3 prior systemic therapies; 40% had prior KRASi. Both darlifarnib 3 and 5 mg + ada were well tolerated; most common (≥30%) any-grade (Gr) treatment-emergent AEs (TEAEs): 63% diarrhea, 57% nausea, 50% anemia, 43% vomiting, 40% neutropenia, 40% thrombocytopenia. Most common (≥15%) Gr ≥3 TEAEs: 30% neutropenia, 17% anemia. 1 dose limiting toxicity occurred (anemia, darlifarnib 5 mg + ada). Most common treatment (trx) discontinuation reason was progressive disease (n=10). With a median follow-up of 23 wks, 13 pts remained on trx. Preliminary results from 25 response-evaluable pts (≥1 darlifarnib dose + post BL scan) included confirmed + unconfirmed responses. Antitumor activity was observed in all tumor types. Across darlifarnib 3 and 5 mg + ada dose levels, ORRs (95% CI) were 67% (22.3–95.7) for NSCLC, 60% (14.7–94.7) for PDAC, 14% (1.8–42.8) for CRC (Table); DCRs (CR+PR+SD): 83% (35.9–99.6) for NSCLC, 100% (47.8–100) for PDAC, 71% (41.9–91.6) for CRC. Updated data across all doses to be presented. **Conclusions:** Darlifarnib 3 and 5 mg + ada were well tolerated with encouraging antitumor activity in heavily pretreated *KRAS* G12C mut NSCLC, PDAC and CRC. These preliminary data support further investigation of darlifarnib + KRASi, such as ada, to address mTORC1-mediated resistance and potentially improve clinical outcomes for pts. Clinical trial information: NCT06026410. Research Sponsor: Kura Oncology, Inc.; Bristol Myers Squibb.

A phase 2 multi-center pharmacodynamic study of the fatty acid synthase (FASN) inhibitor TVB-2640 in advanced *KRAS*-mutant non–small cell lung cancer. First Author: Arthi Sridhar, Harold C. Simmons Cancer Institute, UT Southwestern Medical Center, Dallas, TX

Background: Preclinical and translational studies demonstrate that KRAS-mutant NSCLC has a unique metabolic dependence on de novo fatty acid synthesis, mediated by fatty acid synthase (FASN) and downstream lipid metabolism pathways that support saturated fatty acid production, enabling rapid tumor growth, survival, and resistance to lipid peroxidation. TVB-2640 is an orally bioavailable and selective FASN inhibitor that blocks the β-ketoacyl reductase step of fatty acid synthesis and has demonstrated antitumor activity in *KRAS* mutant NSCLC models. **Methods:** This single-arm trial (NCT03808558) enrolled patients with previously treated, advanced *KRAS* mutant NSCLC. Eligible patients had progressed on prior platinum-based chemotherapy (100%) and immune checkpoint inhibition (95%), had measurable disease by RECIST v1.1, ECOG performance status 0–1, and adequate organ function. One patient had received prior KRAS directed therapy. TVB-2640 100 mg/m^2 (equivalent to two to four 50-mg tablets) was administered orally once daily in continuous 28-day cycles. Exploratory correlative analyses included ^{11}C-acetate PET, plasma lipidomics, sebaceous lipid profiling, and quality-of-life measures. **Results:** Among 18 enrolled patients, the median age was 69 years, 12 (67%) were male, 14 (78%) were white and 13 (72%) had a history of smoking. Median number of prior lines of therapy was 4. The most common *KRAS* mutations were G12V (44%), G12C (17%), and G12D (17%). No patients had a radiographic response, 7 (39%) had stable disease, 9 (50%) had disease progression, and 2 (11%) were non-evaluable. Five patients (28%) had radiographic shrinkage of target lesions but did not achieve partial response due to the magnitude of decrease (n = 3) or progression of non-target lesions (n = 2). Median progression-free survival was 1.8 months (95% CI, 1.7-1.8 months). Overall, 84% of patients had adverse events (AE). Most common AEs were xerostomia (50%), dry skin (44%), and fatigue (39%). Most common grade ≥ 3 AEs (44%) were fatigue, dermatological toxicities, xerostomia, ocular toxicities and anemia (11% each). **Conclusions:** Single-agent FASN inhibition with TVB-2640 in heavily pretreated *KRAS* mutant NSCLC did not meet the primary endpoint of response. Since FASN is a downstream effector of mutant KRAS, combination regimens with KRAS inhibitors can be considered as a future approach in NSCLC. Ongoing correlative studies may further inform the use of this agent. Despite not meeting its primary endpoint, this clinical trial highlights a novel therapy targeting energy metabolism in lung cancer. Clinical trial information: NCT03808558. Research Sponsor: Gateway Foundation for funding the clinical trial; Sagimet for provision of product/material.

Pan-cancer landscape and real-world management of BRAF non-V600E and MAP2K1 alterations: Analysis from the WAYFIND-R registry. First Author: Esranur Aydın, Istinye University, Istanbul, Turkey

Background: While targeted therapies have revolutionized the management of BRAF V600E-mutant tumors, non-V600E BRAF and MAP2K1 alterations remain a clinical "gray zone." These variants represent a functionally diverse group of drivers with no established treatment guidelines, often leading to heterogeneous care and suboptimal outcomes. We used the multinational WAYFIND-R registry to map the prevalence and functional landscape of these rare alterations and to evaluate real-world treatment patterns. **Methods:** We retrospectively analyzed 4,774 patients with solid tumors from the multinational WAYFIND-R registry (NCT04529122). Patients with BRAF and MAP2K1 alterations identified via Next-Generation Sequencing (NGS) were included. Variants were categorized by functional class (Class I-III). Clinical characteristics, co-mutation profiles, and treatment sequences were analyzed to correlate molecular features with management strategies and outcomes. **Results:** Rare alterations were identified in 38 (0.8%) patients, predominantly in colorectal (29%), lung (13%), and melanoma (13%) cancers. Genomic analysis revealed a complex landscape. Among BRAF-altered patients (n=30), while Class I (V600E/K) accounted for 63.3% (n=19), the remaining 36.7% comprised non-V600E variants distributed between functional Class II (20.0%) (e.g., G469A, L597S) and Class III (13.3%) (e.g., D594N, G466R). MAP2K1 alterations (n=9) were distributed across RAF-dependent Class I (44.4%), RAF-regulated Class II (44.4%), and RAF-independent Class III (11.1%) variants (e.g., E102_I103del). Treatment patterns were highly inconsistent. While first-line therapy typically consisted of standard chemotherapy or anti-PD-1 monotherapy, there was no consensus for subsequent lines. This lack of targeted approach correlated with poor outcomes in lung and colorectal cohorts. However, in contrast to unselected treatments, we observed durable responses with biology-guided MEK inhibitor plus Immunotherapy combinations in two index cases. A patient with MAP2K1 Class III (E102_I103del) NSCLC achieved a near-complete metabolic response with cobimetinib + nivolumab. Similarly, a BRAF Class II (G469A) NSCLC patient achieved a complete metabolic and molecular response (confirmed by ctDNA clearance) with trametinib + pembrolizumab. **Conclusions:** This analysis confirms that >35% of BRAF-altered patients (nonV600 mutants) and all MAP2K1-altered patients in real-world settings currently lack standardized treatment protocols. The observed clinical heterogeneity highlights a significant unmet need. Our findings suggest that integrating functional subclassification into clinical decision-making and utilizing targeted combinations is necessary and may offer a viable strategy. Clinical trial information: NCT04529122. Research Sponsor: F. Hoffmann-La Roche Ltd.

3081 Poster Session

First data disclosure from the first-in-human phase 1/2 trial of SMP-3124LP, the first investigational pegylated liposome CHK1 inhibitor, in patients with selected advanced solid tumors. First Author: Timothy A. Yap, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Checkpoint kinase 1 (CHK1) is a critical in the DNA damage response pathway and an important target for anticancer therapy. However, clinical development of CHK1 inhibitors has been limited by myelosuppression and a narrow therapeutic window. The use of liposomal technology potentially widens the therapeutic window by lowering rates of hematologic toxicities minimizing drug exposure to healthy tissues and maximizing delivery to tumors. SMP-3124 is a structurally distinct CHK1-selective inhibitor designed to be optimally delivered in a PEGylated liposome formulation. SMP-3124LP is being developed for malignancies with high replication stress. **Methods:** This ongoing Phase 1/2 study evaluated the safety, tolerability, PK, and preliminary antitumor activity of SMP-3124LP given intravenously (NCT06526819). The dose escalation included patients (pts) with selected advanced solid tumors. **Results:** As of 28 Nov 2025, 42 pts were enrolled at 20, 40, 60, and 90 mg/m^2 every 2 weeks. 23 pts (55%) had ≥4 prior lines of therapy. No dose-limiting toxicities (DLTs) were observed at 20 or 40 mg/m^2. A DLT of Grade (G) 4 thrombocytopenia was noted at 60 mg/m^2 and one pt had 2 DLTs of reversible G4 thrombocytopenia and G3 febrile neutropenia at 90 mg/m^2. Most common treatment-related adverse events (≥20%) were neutropenia (45%), infusion-related reactions (IRR, 38%), thrombocytopenia (36%), anemia (24%) and leukopenia (21%). Treatment-related G3/4 neutropenia was 33%, G3/4 thrombocytopenia and G3 anemia were 9.5% each. Cytopenias were generally transient and none led to treatment discontinuation. All IRRs were G1/2 and manageable with premedications, supportive care, and/or slower infusion rates. Dose-proportional increases in C_{max} (4.3-fold) and AUC (6.0-fold) were observed from 20 to 90 mg/m^2 with low volume of distribution (1.99 to 2.68 L) and a geometric mean half-life of 23 to 31 hours. As of 13 Jan 2026, disease control rate (DCR) was 49%, with 5 RECIST v1.1 partial responses (PR) + 12 RECIST v1.1 stable disease (SD) out of 35 efficacy evaluable patients. Among the PRs, 2 platinum-resistant ovarian cancer (PROC, one with prior PARPi), 2 anal SCC, and 1 colorectal cancer with FBXW7 mutation. 2 other advanced PROC pts had SD with tumor shrinkage 20% or more (one with -88% CA125 response). The anal SCC and rectal cancer pts all received ≥4 prior lines of therapy. Duration of response has not been reached. **Conclusions:** SMP-3124LP was generally well tolerated and had a manageable safety profile. The liposomal formulation appears to reduce the incidence of cytopenias compared to historical data with non-liposomal CHK1 inhibitors. Dose-proportional increases in PK were observed. Promising signals of antitumor activity were observed with 5 RECIST v1.1 PRs and 49% DCR in pts with heavily pretreated cancers. Clinical trial information: NCT06526819. Research Sponsor: Sumitomo Pharma America, Inc.

Real-world characterization of SEZ6, a transmembrane protein expressed in various solid tumors. First Author: Afshin Dowlati, University Hospitals Seidman Cancer Center and Case Western Reserve University, Cleveland, OH

Background: Seizure-related homolog 6 (SEZ6) is a transmembrane protein involved in neuronal development that is downregulated in normal adult tissues outside the central nervous system (CNS). It is overexpressed in various solid tumors such as small cell lung cancer (SCLC), neuroendocrine neoplasms (NENs), and CNS tumors, with strong correlations between mRNA and protein expression. In SCLC, limited data suggest that *SEZ6* expression is greater in molecular subtypes with neuroendocrine (NE)-high gene signatures (i.e., SCLC-A and SCLC-N) than in non-NE subtypes (i.e., SCLC-P). However, *SEZ6* expression in tumor tissues remains poorly understood and existing data are limited by small sample sizes. This study aimed to characterize *SEZ6* expression in a large patient population, across multiple tumor types. **Methods:** Pan-tumor data from a real-world database (Tempus AI, Inc.) were analyzed for *SEZ6* mRNA expression in 37,645 samples, with a focus on lung, brain, and NE tumor types. In SCLC, *SEZ6* expression was compared between SCLC-A, -N, -P, and -I samples via hierarchical clustering. Gene expression was reported as $\log_2$(transcripts per million [TPM]+1). **Results:** Across the 37,645 samples analyzed, tumor types with the highest median ($\log_2$[*SEZ6* TPM+1]) expression were astrocytoma (5.8; n=354), glioma (5.8; n=502), NENs (5.7; n=2794), and glioblastoma (5.6, n=2833). Among NENs, the highest *SEZ6* expression was seen in prostate neuroendocrine carcinoma (NEC) (6.6; n=176), SCLC (6.5; n=2018), and bladder small cell NEC (6.5; n=139). Median *SEZ6* expression was 3–45-fold higher than other biomarkers of interest in SCLC (*B7-H3*, 3-fold; *DLL3*, 3-fold; *CD274* [PD-L1], 28-fold; *PDCD1* [PD-1], 45-fold). In SCLC samples, median *SEZ6* expression was stable across primary (6.4) and metastatic (6.5) tumors and stage II to IV disease (6.6–6.5). Among SCLC molecular subtypes, median *SEZ6* expression was lower in non-NE SCLC-P tumors (3.8; n=85) than in SCLC-I (6.0; n=175), or in NE-high SCLC-N (6.7; n=339) and SCLC-A (7.3; n=224) tumors. *SEZ6* expression was 6–7-fold higher in prostate NEC than in non-NE metastatic prostate adenocarcinoma (castration resistant, 6-fold; castration sensitive, 7-fold). **Conclusions:** *SEZ6* is highly expressed in SCLC and tumors of NE origin, particularly prostate and bladder NEC. In SCLC, *SEZ6* expression is higher than other targets of antibody–drug conjugates (ADCs) approved or in development for SCLC, supporting SEZ6 as a promising therapeutic target. *SEZ6* expression is highest in SCLC-A and SCLC-N molecular subtypes. High *SEZ6* expression is also seen in SCLC-I, a subtype associated with platinum resistance, suggesting SEZ6 may be a potential therapeutic target in certain patients with platinum-refractory SCLC. Taken together, these results suggest cross-indication applicability of targeting SEZ6, highlighting its potential as a multi-tumor ADC target warranting further investigation. Research Sponsor: Whitehawk Therapeutics.

Convenience vs. complexity: Adoption of subcutaneous PD-(L)1s in lung cancer in EU4+UK. First Author: Federico Gallo, Ipsos Insight, New York, NY

Background: Subcutaneous (SC) PD-(L)1 formulations represent a significant step towards simplifying treatment administration by reducing treatment time, compared to intravenous (IV) preparations. To date, the EMA has approved three SC PD-(L)1s: atezolizumab, nivolumab, and pembrolizumab. Here, we evaluate how the availability of SC formulation is affecting physicians' prescribing behaviour, the drivers of the switch from IV to SC, and potential barriers affecting decisions in the treatment of lung cancer in EU4+UK. **Methods:** The Ipsos' Global Oncology Monitor is a physician-reported syndicated patient record database. This analysis comprises 2,537 cancer-treating physicians in EU4+UK, screened for seniority and caseload, submitting data on 36,383 lung cancer patients, online, from January 2024 to November 2025. Physicians who treated lung cancers also completed a perceptual questionnaire on SC PD-(L)1 usage in lung cancer. Responses were collected from 150 physicians in EU4+UK, online, from October to December 2025. **Results:** Adoption of SC PD-(L)1 in lung cancer in EU4+UK is at 6% in the 3 months ending November 2025 compared to 94% of the IV format. We observed that SC PD-(L)1 was more likely used as monotherapy while the IV formulation in combination therapy (Table 1). Among patients receiving the IV version, 13% have a planned switch to SC, 71% do not, while 16% remained classified as the physician being undecided. Of those who would switch/undecided, the switch was estimated to happen after a mean of 4.5 cycles on the IV formulation. **Conclusions:** In this study, the uptake of SC PD-(L)1 reflects its clear benefit in reducing treatment time; however, the IV formulation remains dominant, suggesting physician hesitancy toward the SC format. While shorter administration time is beneficial, it does not yet outweigh concerns regarding patient comfort. Crucially, SC usage is notably lower in combination therapies compared to monotherapy. This suggests that when IV chemotherapy is required, the convenience of an SC add-on is diminished. Furthermore, the perception that SC offers 'no additional value' over the established IV contributes to this inertia. To drive adoption and improve patient experience, manufacturers must address administration-related discomfort and effectively communicate the comparative efficacy and workflow benefits of the SC formulation, particularly for patients who have yet to switch. Further investigation to assess any country differences and patient point of view will be beneficial. Research Sponsor: None.

Usage of PD-(L)1 by formulation.

	Subcutaneous n=123	Intravenous n=1,914
Monotherapy	72%	41%
Combination	28%	59%

Targeting cancer stem cells with a novel virus-like drug conjugate. First Author: Stevie Fawcett, CCR, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Belzupacap sarotalocan (bel-sar) is a novel virus like-drug conjugate in clinical stage development for multiple solid tumors. The virus-like particle component of the drug is derived from the papillomavirus and specifically binds to heparan sulfate proteoglycans (HSPGs) and chondroitin sulfate proteoglycans (CSPGs) with unique sulfation modifications on the surface of cancer cells. Upon activation with near-infrared light, cell associated bel-sar causes immediate cell death and induces an anti-tumor immune response, with a single administration leading to elimination of solid tumors accompanied by long-term protective immunity in a number of animal tumor models. Cancer stem cells (CSCs) represent a distinct subpopulation of tumor cells that possess stem-like characteristics, including self-renewal. These cells are thought to drive disease persistence and are intrinsically more resistant to conventional cancer treatment, such as chemotherapy, radiotherapy, and immunotherapy. CSC-mediated resistance remains a major obstacle to achieving durable clinical responses and the elimination of this cell population is hypothesized to be essential for long-lasting tumor control. **Methods:** We developed and characterized a panel of human-derived CSC models (bladder, breast, oropharyngeal, prostate cancers, glioblastoma, uveal melanoma) using a SORE6 lentivirus reporter in which stem-like transcription factors SOX2 and OCT4 drive GFP expression to identify CSC subpopulations. Bel-sar binding and potency was compared between CSC and the more differentiated non-cancer stem cells (nCSC) populations. Additionally, chemotherapy resistant tumor lines were established from the CSC panel and were similarly tested for bel-sar targeting and cytotoxicity. **Results:** CSC populations were validated by SOX2/OCT4 co-expression, CSC surface marker expression (CD24, CD44, EpCAM-1, CXCR4), ALDH activity, and tumorsphere formation. Bel-sar was capable of binding CSCs with equal or enhanced efficiency as compared to nCSCs through cell surface HSPGs and CSPGs as demonstrated by heparin and chondroitin sulfate inhibition. Additionally, bel-sar was able to kill CSCs and nCSCs with equal efficiency in vitro. Following chemotherapy-induced enrichment of CSCs, bel-sar maintained its therapeutic effect on chemotherapy-resistant CSC populations, reinforcing previous data demonstrating complete responses in animal models. **Conclusions:** This study highlights bel-sar's distinctive capacity to target and eradicate CSCs across diverse tumor types. These results support bel-sar's clinical development for local tumor control and suggest bel-sar treatment may be effective against recurring or chemotherapy-resistant tumors. Targeting TP53 pathologic variants for cancer immunotherapy using a self-replicating mRNA vaccine strategy. First Author: Changgan Chen, Fujian Medical University Union Hospital, Fuzhou, China

Background: *TP53* pathogenic variants (PVs) are highly prevalent in human malignancies as a whole and especially in patients with pancreatic ductal adenocarcinoma (PDAC). Approximately 80% of TP53 PVs are missense mutations that may be targeted for cancer therapy. **Methods:** We have developed a self-replicating mRNA (srRNA) vaccine (TMG-mut *TP53* srRNA SA-LNP) encoding concatenated p53 mutant peptides encompassing 14 hotspot *TP53* missense mutations in PDAC, encapsulated in sialic acid (SA)-modified lipid nanoparticles (LNPs). These 14 hotspot TP53 PVs were selected by examining four public available datasets and from our previous studies. **Results:** TMG-mut *TP53* srRNA SA-LNPs incorporated Venezuelan equine encephalitis virus replicase which enabled higher and prolonged *in vivo* protein expression compared to conventional mRNA construct. Encapsulation with SA-modified LNPs led to significantly better efficiency in targeting dendritic cells (DCs) *in vitro* and *in vivo* compared to conventional LNPs. We used *in vitro* (cell lines) and *in vivo* assays (PDX and human engineered mouse genetic models) to test the efficacy of our RNA vaccine. We validated the detection of TP53 neoantigen by mass spectrometry generated by our srRNA vaccine. We then tested its anti-tumor immunity by itself alone and in combination with anti-PD1 inhibition using multiple cell lines and PDX that carry different TP53 PV (R175H and R273H). TMG-mut *TP53* srRNA SA-LNP stimulated potent and specific anti-tumor $CD8^+$ T cell responses in *in vitro* and *in vivo* assays using autologous DCs, T cells and cancer cells from multiple PDAC patients. Using both Panc02 syngeneic PDAC cell line and patient-derived PDAC xenografts (PDX), we show that TMG-mut *TP53* srRNA SA-LNP stimulated potent and specific anti-tumor immunity against PDAC tumors that harbor different corresponding p53 PVs. Panc02-$TP53^{R175H}$ tumor-bearing transgenic mice expressing human HLA-A*02:01 treated with TMG-mut *TP53* srRNA SA-LNP showed significantly suppressed tumor growth and prolonged survival with increased tumor infiltration of activated $CD8^+$ T cells as well as increased production of cytokines including type II interferon, TNFalpha, and other biomarkers. We also show our vaccine stimulates increased tumor cell apoptosis. In addition, TMG-mut *TP53* srRNA SA-LNP dramatically enhanced the anti-tumor immunity of anti-PD1 by synergistically suppressing tumor growth and prolonging the survival of tumor-bearing mice in both low and high-tumor burden animal model. **Conclusions:** Our results demonstrate for the first time that missense p53 PVs are valid targets for developing novel cancer immunotherapy using srRNA vaccine approach enhanced by SA-LNPs encapsulation. Our data potentially opens a new approach for developing mRNA vaccine-based immunotherapy for a large population of cancer patients as TP53 PVs are highly prevalent in nearly every type of malignant tumors. TSY-310, a novel bispecific EGFR×ROR1 ADC: Assessment of antitumor activity in heterogeneous breast tumors through enhanced internalization and bystander cytotoxicity. First Author: Kuo-Ming Yu, Formosa Pharmaceuticals, Inc., Taipei, Taiwan

Background: Epidermal growth factor receptor (EGFR) is a clinically validated target and is highly expressed in various solid tumors, including triple-negative breast cancer (TNBC). Clinical efficacy of EGFR-directed therapies in TNBC, however, is often limited by intratumoral heterogeneity, acquired resistance, and mutations conferring insensitivity to tyrosine kinase inhibitors. TSY-310 is a novel bispecific EGFR×ROR1 nanobody-Fc fusion antibody–drug conjugate (BsADC) designed to address these challenges by simultaneously targeting EGFR and receptor tyrosine kinase-like orphan receptor 1 (ROR1). TSY-310 carries an average of 3.6 molecules of monomethyl auristatin E (MMAE) via a protease-cleavable valine–citrulline linker, enabling potent and tumor-selective cytotoxicity, and induces strong tumor regression across multiple NSCLC PDX models representing a range of EGFR and ROR1 expression levels. **Methods:** Cytotoxicity was evaluated in cell lines with distinct EGFR/ROR1 expression profiles. Bystander killing was assessed in co-culture systems of antigen-positive and antigen-negative cells. Cellular internalization and trafficking were analyzed by immunofluorescence microscopy. In vivo efficacy and bystander activity are investigated in xenograft models with heterogeneous antigen expression. **Results:** TSY-310 exhibited sub-nanomolar cytotoxicity (IC_{50} = 0.45 nM) against MDA-MB-468 ($ROR1^+$/$EGFR^+$) TNBC cells in correlation with dual receptor expression levels, and demonstrated robust bystander killing, eliminating neighboring antigen-negative A427-Luc and MDA-MB-453-Luc cells through MMAE diffusion in co-culture systems. Rapid internalization of TSY-310 was observed in dual-positive MDA-MB-468 cells within 6 hours, consistent with enhanced cytotoxic activity. In a $EGFR^+$/$ROR1^+$ HBCx-28 TNBC PDX model, it achieved complete and sustained tumor regressions in all treated mice (5/5) and demonstrated superior efficacy compared with the monospecific ROR1-directed ADC on a payload-equivalent basis. In vivo studies to assess bystander activity and efficacy in heterogeneous tumor models are ongoing. **Conclusions:** These findings highlight TSY-310 as a first-in-class bispecific ADC capable of overcoming tumor heterogeneity through dual binding and bystander killing, supporting its potential as an effective therapeutic agent for heterogeneous solid tumors such as TNBC, where existing EGFR-targeted therapies have shown limited benefit. Influence of genetic ancestry on UV mutational signatures linked to immunotherapy response in melanoma, beyond TMB. First Author: Kevin Magnaye, Caris Life Sciences, Irving, TX

Background: Melanoma is a UV-driven malignancy with substantial biological heterogeneity, yet genomic profiling efforts have historically underrepresented diverse ancestral backgrounds, limiting insights into population-level differences in tumor biology and treatment response. **Methods:** In this retrospective study, a supervised machine learning framework was developed to infer genetic ancestry across 483,454 tumors profiled by tumor-only whole-exome sequencing (WES) at Caris Life Sciences (Phoenix, AZ), using 36,962 ancestry-informative variants derived from globally diverse Genome Aggregation Database (gnomAD) reference individuals (n=4,150). Survival outcomes inferred from claims data were evaluated using Cox proportional hazard ratios (HR) with 95% confidence intervals (CI) and log-rank p-values. Associations between features were evaluated using standard statistical tests and regression models. **Results:** We applied this framework to cutaneous melanoma (N=8,872). The UVB-related COSMIC mutational signatures SBS7a and SBS7b were markedly enriched in tumors from patients (pts) of European (EUR) ancestry (93.2% and 75.6%, respectively) but were uncommon in African ancestry tumors (6.9% and 5.2%). Within EUR ancestry pts, higher EUR ancestry fraction was associated with higher SBS7a and SBS7b prevalence ($p=9.0x10^{-4}$ and $1.5x10^{-4}$), consistent with known differences in pigmentation biology and melanoma etiology. Among 3,587 melanoma pts treated with first-line immune checkpoint inhibitors (ICI), SBS7a positivity was strongly associated with improved overall survival (OS HR [95% CI] = 0.55 [0.46–0.66]) and time to next treatment (TTNT HR=0.58 [0.49–0.69]; all $p<0.001$), outperforming tumor mutational burden (TMB) as a prognostic biomarker. SBS7a+ remained prognostic in a multivariable Cox analysis accounting for TMB, age, sex, and the first two ancestry principal components. Furthermore, both SBS7a+ TMB-high and SBS7a+ TMB-low tumors demonstrated superior outcomes compared to SBS7a– TMB-low tumors (OS HR=0.49 [0.41–0.60] and 0.62 [0.51–0.74], respectively; all $p<0.001$). Similar patterns were observed in cutaneous squamous cell carcinoma. To assess specificity for UV-driven biology, we evaluated two non-sun-exposed malignancies: uveal melanoma and renal cell carcinoma (RCC). SBS7a was virtually absent in uveal melanoma and RCC (6.7% and 6.9%, respectively, among EUR ancestry pts) and did not stratify ICI outcomes in either cancer. These negative controls suggest that SBS7a does not arise without UV exposure and is not a general immunotherapy biomarker. **Conclusions:** These findings establish a scalable genetic ancestry framework, reveal ancestry-linked differences in melanoma mutagenesis, and demonstrate that SBS7a provides clinically meaningful, TMB-independent prognostic information specific to UV-driven tumors. Research Sponsor: None.

A phase 1, first-in-human study of OP-3136, a novel oral selective KAT6A/B inhibitor, as monotherapy in advanced solid tumors and in combination with endocrine therapy in ER+, HER2– advanced breast cancer (ABC): Preliminary results. First Author: Amita Patnaik, START Center for Cancer Research, San Antonio, TX

Background: Histone lysine acetyltransferases (KATs) control oncogenic transcription and are frequently dysregulated in cancer. OP-3136 is a potent, selective, oral small-molecule inhibitor of KAT6A/B with preclinical antitumor activity, including in combination with endocrine therapy (ET) (Palanisamy et al, 2024). This phase 1 study evaluates the safety, tolerability, pharmacokinetics (PK), and preliminary antitumor activity of OP-3136 as monotherapy in advanced solid tumors and in combination with fulvestrant or palazestrant (a novel oral complete estrogen receptor antagonist [CERAN] and selective estrogen receptor degrader [SERD]) in ER+, HER2– ABC (NCT06784193). **Methods:** Patients (pts) with ABC, metastatic castration-resistant prostate cancer (mCRPC), or non-small cell lung cancer (mNSCLC) received OP-3136 once daily (QD) as monotherapy (no limit on prior lines of therapy), and a separate cohort of ABC pts received OP-3136 + fulvestrant in a phase 1 study using a Bayesian Optimal Interval dose-escalation. **Results:** As of 26 November 2025, 32 pts ABC, n=23; mCRPC, n=8; and mNSCLC, n=1) received OP-3136 (monotherapy, n=25; in combination with fulvestrant, n=7) across doses of 2–45 mg QD. All ABC pts received prior endocrine therapy and CDK4/6 inhibitors, all mCRPC pts received prior androgen receptor–targeted therapy. The median (min – max) of prior anticancer systemic therapy lines was 3 for ABC (1–5) and 5 (1–8) for mCRPC pts. The median time on treatment was approximately 2 months (max 47 months). In the monotherapy cohort, treatment-related adverse events (TRAEs) were mostly grade (G)1–2. The most common (≥25%) TRAEs included dysgeusia (72%; G2, 24%), anemia (40%; G3, 8%), fatigue (32%; G2, 16%), and neutropenia (28%; G3, 20%). In the combination cohort, TRAEs were predominantly G1–2 with one G3 neutropenia and leukopenia. No dose-limiting toxicities (DLTs), G4-5 TRAEs or treatment discontinuations due to TRAEs were reported. Across monotherapy dose levels, among 14 pts with measurable disease, reduction of target lesions occurred in 64% (9/14) and 2 pts (1 with ABC and 1 with mCRPC) had partial responses (unconfirmed). Among 17 pts with evaluable disease,10 had stable disease. PK analyses showed dose-proportional exposure of OP-3136 with rapid absorption and sustained systemic exposure over the dosing interval supporting QD administration. **Conclusions:** OP-3136 demonstrated a manageable safety profile and favorable PK, both as monotherapy and in combination with fulvestrant. Preliminary evidence of antitumor activity in ER+ HER2- ABC and mCRPC was observed in these heavily pretreated pts. Dose escalation and enrollment in combination with fulvestrant or palazestrant are ongoing and updated data will be presented. Clinical trial information: NCT06784193. Research Sponsor: Olema Oncology.

3089 **Poster Session**

A phase 1a/b study of RGT-61159, an oral MYB splicing modulator, in patients with advanced adenoid cystic carcinoma and colorectal cancer. First Author: Alan Loh Ho, Solid Tumor Oncology Division, Head and Neck Service, Memorial Sloan Kettering Cancer Center, New York, NY

Background: MYB is a master regulator of cell proliferation, self-renewal, and differentiation processes and its aberrant expression is found in multiple forms of human cancer including adenoid cystic carcinoma (ACC), acute myeloid leukemia, T-cell acute lymphoblastic leukemia, colorectal cancer (CRC), small cell lung cancer, and breast cancer. RGT-61159 is an orally available small molecule designed to selectively modulate splicing of the oncogenic transcription factor MYB, resulting in downregulation of MYB protein levels and tumor cell death. **Methods:** This ongoing Phase 1a/b, multi-center, open-label clinical trial evaluates RGT-61159 in patients (pts) with advanced, relapsed or refractory ACC or CRC. Pts with ACC must have disease progression within 12 months of study entry. The study employs a 3+3 dose-escalation design with daily oral dosing in 21-day cycles, starting at 6 mg and escalating using a Fibonacci scheme. Primary objectives are to assess safety and tolerability and determine the recommended Phase 2 dose (RP2D). Secondary objectives include characterization of pharmacokinetics (PK), pharmacodynamics (PD), and preliminary anti-tumor activity. **Results:** As of 22 December 2025, 44 pts (86% ACC, 14% CRC) were treated across 8 dose levels (6–144 mg). In pts with ACC, median age was 61 years (range: 33–77) and median prior lines of therapy was 1 (range: 0-6); 47% were female. In pts with CRC, median age was 63 years (range: 44–72) and median prior lines of therapy was 5.5 (range: 4-8); 50% were female. Dose-limiting toxicities (DLTs) occurred in three pts: G3 nausea and muscle weakness, G3 fatigue, and missed doses due to G2 atrial flutter. Treatment-emergent adverse events (TEAEs) observed in ≥20% of pts were diarrhea, nausea, fatigue, dyspnea, and anemia. One G3 vasculitis (144 mg) and dose-related inflammatory edema events (G2 at 108/144 mg; G1 at lower doses) occurred; none were protocol-defined DLTs. Overall, RGT-61159 was well tolerated at or below the provisional RP2D of 84mg. 19 pts remain on treatment, including 9 pts (all with ACC) treated from 24 to 60mg who have been on study for more than 6 months with durable stable disease. In 35 evaluable pts, 18 have had tumor regressions with one partial response (RECIST v1.1) observed in a pt with ACC treated at 60mg. After the data cut, another pt with ACC treated at 84mg also achieved a partial response. Dose-dependent, robust knockdown of MYB in the peripheral blood was observed (up to 75% at 84mg). Plasma exposure increased approximately dose-proportionally with low to moderate variability. **Conclusions:** RGT-61159 is well tolerated at doses at or below the provisional RP2D. Robust peripheral knockdown of MYB was observed in a dose-dependent fashion at clinically relevant doses. Clinical activity manifested as prolonged stable disease and a partial responses primarily in pt with ACC. Clinical trial information: NCT06462183. Research Sponsor: Rgenta Therapeutics.

Genomic landscape of *ERBB3* alterations in 5,416 metastatic solid tumors: Real-world evidence regarding biomarker-agnostic ADC strategies. First Author: Minsuk Kwon, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: While ERBB2 (HER2) is a well-established therapeutic target, the clinical significance and genomic landscape of ERBB3 (HER3) across diverse solid tumors are less defined. As HER3 emerges as a critical mediator of resistance and a target for novel antibody-drug conjugates (ADCs), characterizing its genomic alterations in a real-world setting is essential to refine therapeutic positioning. **Methods:** We analyzed clinical next-generation sequencing (NGS) data (Illumina TSO 500 or Oncomine Comprehensive Assay Plus) from 5,416 patients with metastatic solid tumors at a single tertiary center (Samsung Medical Center) between 2019 and 2025. ERBB3 alterations were categorized into mutations (SNVs/indels, VAF $\geq$2%) and amplifications (copy number [CN] $\geq$4). **Results:** ERBB3 alterations were identified in 12.9% (697/5,416) of patients. The prevalence was overwhelmingly driven by mutations (12.3%), while amplifications were rare (0.6%). The highest mutation frequencies were observed in: Urothelial carcinoma, 18.2%; Malignancy of unknown origin, 16.3%; and Biliary tract cancer, 15.7%. The most frequent variants were K498I (Domain IV) and R1127H (C-terminal tail). Known oncogenic hotspots (V104, A232V, G284R, E928G) were present but not dominant. Notably, the ERBB3-mutated cohort exhibited high co-mutation rates with canonical drivers: TP53 (66%), APC (35%), and KRAS (31%). In common GI cancers, ERBB3 mutations frequently co-occurred with APC and KRAS, suggesting they often act as "passenger" or secondary events rather than primary drivers. High-level amplifications (CN $\geq$8) were rare ($<$0.1%) and appeared in isolated cases across various histologies. **Conclusions:** ERBB3 alterations are relatively common (12.9%) in metastatic solid tumors but are characterized by a diverse mutational landscape rather than focal amplifications. The high frequency of co-occurring canonical drivers suggests that HER3 primarily functions as a resistance hub or facilitator in these tumors. These real-world data provide a strong genomic rationale for biomarker-agnostic ADC strategies (targeting HER3 protein expression) rather than mutation-specific approaches in most ERBB3-altered solid tumors. Research Sponsor: None.

Phase Ib expansion and dose optimization study of CX-5461 in patients with solid tumours enriched for DNA-repair deficiencies. First Author: Ana Veneziani, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: G-quadruplexes (G4) are guanine-rich DNA/RNA structures that contribute to DNA damage and genomic instability. Pidnarulex (CX-5461) is a first-in-class G4 stabilizer that induces synthetic lethality in Homologous Recombination-deficient (HRD) cells. Previous phase 1 study showed safety and preliminary activity. Here we report dose optimization for recommended phase 2 dose (RP2D) of CX-5461 and confirm safety. **Methods:** CX-5461 was administered intravenously on Days 1 and 8 of a 28-day cycle at 2 dose levels (250 and 325 mg/m²) in patients (pts) with advanced pancreatic adenocarcinoma (PA), breast cancer (BC), or ovarian cancer (OC). The main cohort (Arms A: 250 mg/m² & B: 325 mg/m²) included pts with HRD or DNA damage response (DDR) alterations and has completed accrual. An exploratory cohort (Arms C: 250 mg/m² & D: 325 mg/m²) of OC pts with BRCA or other HRD genes enrolled simultaneously. Primary objective is to determine RP2D of CX-5461 using Relative Dose Intensity (RDI). Secondary objectives are safety, tolerability and efficacy. **Results:** 54 pts were treated and evaluable for toxicity (Arm A = 18, Arm B = 18, Arm C = 10, Arm D = 8). Patients' characteristics and efficacy results are detailed in table 1. The median number of prior lines of treatment were 6 (1-14). The median number of CX-5461 cycles received were 2 (1-30) and weeks on treatment were 8 (4-120). Grade $\geq$3 Treatment-Related Adverse Events (TRAEs) occurred in 12 pts (22%), including proteinuria, thrombocytopenia, and fatigue; 6 (11%) were AEs of special interest: 1 (2%) palmar-plantar erythrodysesthesia, 4 (7%) photosensitivity, and 1 (2%) phototoxic drug eruption. Among 29 response-evaluable pts in main cohort, 1 had PR (3%) and 10 had SD (34%),median duration 16 weeks (wks) (8-84). In evaluable OC (n=29), 2 had PR (7%), 13 SD (44%), median duration 16 wks (8-84). OC pts with BRCA mutations (n=25) had 2 PR (8%) and 11 SD (44%); all had prior PARPi exposure. 3/ 5 non-BRCA HRD had SD (60%). Prolonged clinical benefit was observed in 4 pts with treatment durations of 14 (OC, gBRCA1), 17 (OC, gBRCA2), 21 (OC, sBRCA1) and 30 cycles (PA, gPALB2). RDI was 91% in Arm A and 88% in Arm B. RDI and clinical data support 250 mg/m² as the RP2D. **Conclusions:** CX-5461 was tolerable and showed evidence of durable disease control in heavily pretreated pts, enriched for HRD/DDR alterations and post exposure to PARPi. The 250 mg/m² dose is established as the RP2D based on clinical data and RDI. Correlative studies are ongoing. Clinical trial information: NCT04890613. Research Sponsor: None.

Topoisomerase 1 and DNA damage: Pharmacodynamic responses and mechanism of trastuzumab deruxtecan in HER2- expressing advanced solid tumors. First Author: Deborah Wilsker, National Cancer Institute Frederick National Laboratory for Cancer Research, Frederick, MD

Background: Trastuzumab deruxtecan (T-DXd) consists of deruxtecan, a novel topoisomerase 1 (TOP1) inhibitor, covalently bound via a lysosomal protease-cleavable linker to the human epidermal growth factor receptor 2 (HER2)-targeting antibody, trastuzumab. The mechanism(s) underlying the clinical activity seen in multiple tumor types across various HER2 levels is of ongoing, active interest. To investigate the T-DXd mechanism of action, we developed a pilot clinical trial of T-DXd with a detailed pharmacodynamic analysis from TOP1 target engagement to downstream effects of DNA damage in patients with HER2-expressing (IHC 1-3+, HER2 amplified, or HER2 mutated) advanced solid tumors (NCT04294628). **Methods:** Based on preclinical studies modeling the trial, research tumor biopsies from consenting patients were collected at three time points: pre-treatment, post-dose Cycle 1 (48-96 hours) and pre-dose Cycle 3. The biopsies were evaluated for TOP1 inhibition, induction of stabilized TOP1covalent complexes (TOP1cc) and induction of downstream DNA damage repair (DDR) markers (RAD51, pNBS1, RPA32) using validated, quantitative multiplex immunofluorescence assays on fixed tumor sections with image analysis methodology. In addition, a retrospective analysis of Schlafen 11 expression in baseline biopsies was performed to determine its predictive value of tumor responses to T-DXd. **Results:** Twenty-one biopsy pairs (pre-treatment and C1, 48-96h post-dose 1) were evaluable for TOP1 molecular response and downstream DDR marker induction. TOP1 target modulation was detected in 15 (71%) of the on-treatment biopsies and markers of DDR were induced in 18 (86%) biopsy pairs. TOP1 target inhibition, robust induction of downstream DNA damage response including stalled replication fork progression, and DNA breaks were observed in HER2-amplified/2+/3+ tumors, and in HER2 1+ tumors. **Conclusions:** Our results confirm the intended TOP1 molecular mechanism of action of T-DXd in HER2-amplified/2+/3+ and importantly extend that finding to HER2 1+ tumors, resulting in DNA damage in nearly all cases. Pharmacodynamic biomarker studies are poised to yield important insights into the molecular effects of T-DXd in solid tumors. Research Sponsor: This project was funded in part by the National Cancer Institute, National Institutes of Health, under Contract No. 75N91019D00024.

Chemotherapy as a shaper of immune communication in the triple-negative breast cancer microenvironment. First Author: David Otohinoyi, Louisiana State University Health Sciences Center at Ochsner University Hospital & Clinics, Department of Internal Medicine, Lafayette, LA

Background: Triple-negative breast cancer (TNBC) is a highly immunogenic disease and exhibits among the highest levels of immune infiltration compared with other breast cancer subtypes. These characteristics, coupled with the lack of effective targeted therapies, have made TNBC a key candidate for immunotherapy in selected clinical settings. While chemotherapy remains a mainstay of treatment, its immunomodulatory effects on the tumor immune microenvironment (TIME) remain poorly understood. This study computationally models immune cell to immune cell communication using Single-cell RNA sequencing data to identify immune driver cells and their interactions, and how they are altered by chemotherapy in TNBC. **Methods:** Single-cell RNA sequencing data of over 200,000 tumor cells from TNBC patients' tumor samples were obtained from the Gene Expression Omnibus database. They were analyzed to comprehensively characterize the TIME before and after chemotherapy. We also considered healthy breast tissue to establish immune pathways unique to TNBC pathogenesis. We employed unsupervised clustering analysis, reciprocal principal component analysis with annotation from the NIH Center of Immunology for immune cell identifiers. Communication probability, interaction strength, and pathway information flow were computed, and differential signaling was evaluated using Wilcoxon rank-sum tests ($p < 0.05$). Multiple hypothesis testing was also accounted for by Bonferroni-adjusted p-values to control false positives. **Results:** Immune activity within the TIME was minimal in healthy breast tissue, highlighting signaling pathways specific to TNBC pathogenesis. In contrast, there was an increased immune response in tumors after chemotherapy. Pathways with the highest communication activity included MHC-I/II, CCL, MIF, and CD99 signaling. Notably, CD86 signaling, which correlates with PD-L1 expression, and CD45 signaling were significantly activated after chemotherapy in TNBC. Additionally, CD23 signaling, associated with antitumor immunity, was enhanced following chemotherapy. Natural killer cells emerged as the key immune cell type mediating outgoing signals through annexin, IL16, CX3C, and CD99 pathways, which were largely inactive before treatment. **Conclusions:** Our findings demonstrate that chemotherapy reprograms the TIME in TNBC by enhancing intercellular communication among immune cells and upregulating pro-immune signaling pathways. This remodeling of the TIME suggests potential targets for novel immunotherapeutic discoveries and immune-checkpoint modulation in TNBC. Research Sponsor: None.

Sex-associated differences in osimertinib pharmacokinetics among Asian patients with non-small cell lung cancer. First Author: Sylvia Chen, Clinical Pharmacology Laboratory, National Cancer Centre Singapore, Singapore, Singapore

Background: Osimertinib is an oral, third-generation tyrosine kinase inhibitor (TKI) used in the treatment of epidermal growth factor receptor (EGFR) T790M-positive non-small cell lung cancers (NSCLC). However, therein lies a high interindividual variability in osimertinib trough concentrations at steady state, which may in turn affect clinical outcomes. The study aimed to evaluate factors influencing osimertinib exposure and their potential impact on treatment response. **Methods:** This was a prospective single-institution study of Asian NSCLC patients receiving once daily 80mg osimertinib. Plasma concentrations of osimertinib and its metabolites, AZ5104 and AZ7550 were quantified at steady state using a validated LC-MS/MS method. Pharmacogenetic analysis was conducted using commercially available Taqman SNP genotyping assays. **Results:** A total of 177 Asian patients with Stage I-IV NSCLC tumors were enrolled. Median age was 65 (35-84) years old. Majority of patients were Chinese (90%), female (59%) and non-smokers (82%). Exon 19 deletions were present in 45% of patients. Subgroup analysis of 72 patients with available pharmacokinetic data showed no significant genotypic-phenotypic associations between *CYP3A5*3, ABCB1 1236C>T, ABCB1 3435C>T, ABCB1 2677G>T/A* and *ABCG2 421C>A* and osimertinib pharmacokinetics parameters. Sex was significantly associated with trough osimertinib levels and clearance, with females exhibiting 28% higher osimertinib levels and lower clearance compared with males (P=0.0098). Similar trends were observed with AZ5104 and AZ7550 and osimertinib clearance ($P<0.001$). No significant differences in overall survival and progression-free survival were observed between sexes. Analysis of best overall response showed that males were more likely to PD compared with females (OR=1.88, 95% CI; 0.54- 6.3) but this was not statistically significant (P = 0.489). **Conclusions:** Our study showed that sex influences osimertinib pharmacokinetics, with females showing higher trough levels and lower clearance. These differences did not, however, translate into significant differences in survival or treatment response between males and females. Research Sponsor: NCC Research Fund; NCCRF-YR2017-JAN-PG2.

NeoRay phase IIa results: A study of [^{177}Lu]Lu-NeoB (^{177}Lu-NeoB) in pts with advanced solid tumors overexpressing gastrin-releasing peptide receptor (GRPR). First Author: Erik Mittra, Oregon Health & Science University, Portland, OR

Background: GRPR is overexpressed in many solid tumors. NeoB binds to GRPR with high affinity and can be radiolabeled for theranostics. NeoRay is the first-in-human study of ^{177}Lu-NeoB in pts with advanced solid tumors overexpressing GRPR. Phase (Ph) I reported favorable organ dosimetry and safety, and a recommended Ph II dosage (RP2D) of 9.25 GBq. Here, we report the Ph IIa primary analysis. **Methods:** This Ph IIa, open-label, multicenter, dosage expansion study enrolled 5 adult cohorts with confirmed [^{68}Ga]Ga-NeoB tumor uptake: A) HR+/HER2- breast cancer; B) prostate cancer (PCa); C) gastrointestinal stromal tumor (GIST); D) impaired renal function; and E) pts eligible for Cohorts A–C who also received sacubitril/valsartan (49/51 mg) at Cycle 1 to assess drug-drug interaction (DDI). There was no formal sample size calculation; the target was ~12 pts in Cohorts A–C, $\leq$6 pts in D, and ~3 pts in E. ^{177}Lu-NeoB 9.25 GBq was to be administered every 6 wks for $\leq$9 cycles, except in DDI Cohort E (5.55 GBq in Cycle 1, then 9.25 GBq). Primary endpoints (descriptive statistics) were individual response (centrally assessed by RECIST v1.1) in Cohorts A–C, and ^{177}Lu-NeoB PK and dosimetry in Cohort E. Secondary endpoints included safety/tolerability and QoL. **Results:** Overall, 18 pts (A n = 4; B n = 7; C n = 2; D n = 2; E n = 3) received treatment (median age 65 y; 56% male). Median (range) ^{177}Lu-NeoB exposure was 9 (6–60) wks; median (range) cumulative activity administered was 12.1 (5.7–81.4) GBq. At data cutoff (7 Jan 2025), 4 pts (B n = 2; C n = 2) had completed treatment ($\geq$3 cycles); 1 pt (GIST) received 9 cycles. Of 10 pts with centrally assessed post-baseline response data, 1 had partial response (PCa), 5 had stable disease (of whom 2 had stable disease $\geq$20 wks [GIST]), and 4 had progressive disease. Adverse events (AEs) occurred in 17 (94%) pts (serious AEs in 3 [17%] pts; Gr $\geq$3 AEs in 6 [33%] pts). Treatment-related AEs (TRAEs) occurred in 7 (39%) pts (all non-serious; Gr $\geq$3 in 2 [11%] pts). The most common TRAEs were fatigue (n = 5, 28%), anemia (n = 2, 11% [Gr $\geq$3 in 1 pt, 6%]), and bone pain (n = 2, 11%). One pt died of hepatic failure related to disease progression (not a TRAE). No AEs led to dosage reductions/interruptions/discontinuations. Dosimetry evaluated in 12 pts showed favorable biodistribution, similar to Ph I. Projected cumulative absorbed doses in target organs were below EBRT limits; lesion absorbed doses were generally consistent across cohorts. Mean $\pm$ SD EORTC QLQ-C30 global health scores in Cohorts A–C were 70 $\pm$ 22 at baseline (n = 12) and 73 $\pm$ 16 at Cycle 2 (n = 4), suggesting stable QoL. **Conclusions:** NeoRay Ph IIa data at the ^{177}Lu-NeoB RP2D (9.25 GBq) reinforce Ph I dosimetry and safety results and support further clinical evaluation. Most AEs were mild/moderate and no new safety signals were identified. Despite the limited sample size, preliminary signs of antitumor activity were observed. Clinical trial information: NCT03872778. Research Sponsor: Novartis Pharmaceuticals.

ETCTN 10302: A randomized phase II trial of radium-223 dichloride in combination with paclitaxel in patients with bone metastatic breast cancer. First Author: Jyoti Malhotra, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: Radium-223 dichloride is an alpha particle emitting radiopharmaceutical that mimics calcium and localizes bone metastases inducing double-strand DNA breaks. Tumor cells in M-phase cell cycle arrest from paclitaxel are highly sensitive to alpha-emitting radionuclides. ETCTN 10302 tested the hypothesis that addition of radium-223 to paclitaxel will improve outcomes for bone-dominant metastatic breast cancer. **Methods:** ETCTN 10302 was a randomized, two-arm, multicenter, open-label phase II trial. Patients (pts) were randomized to receive either radium-223 (1.49 microcurie/kg iv day 1 x 6 doses) and paclitaxel (80 mg/kg iv on days 1,8 and 15) of each 28-day cycle (Arm A) or paclitaxel alone (Arm B). Inclusion criteria included HER2-negative metastatic breast cancer with $\geq$2 bone lesions and limited visceral metastases (five or less and $\leq$4 cm in size). Primary endpoint was median progression-free survival (PFS). Exploratory analyses included whole exome sequencing and serum alkaline phosphatase dynamics. **Results:** 70 pts were randomized from August 2020 to May 2024. Median age was 58.5 years, 100% were female, 60% were non-Hispanic whites, 14% had triple negative breast cancer, 37% had bone only disease. In the intent-to-treat analysis (37 Arm A, 33 Arm B), there was no significant difference in median PFS (5.8 vs 5.6 months; HR 0.92 p=0.80) but there was a numeric improvement in median OS in radium-223 plus paclitaxel arm (20.2 vs 16.6 months; HR 0.74 p=0.40). Overall response rate (ORR) was 5% in Arm A vs 9% in Arm B. There was no difference in median OS and PFS when analysis was limited to efficacy evaluable pts who completed at least one cycle (37 Arm A, 24 Arm B). Common treatment-related adverse events (TRAE) with the combination of radium-223 plus paclitaxel vs paclitaxel were anemia (78% vs 54%), neutropenia (76% vs 45%), fatigue (49% vs 50%), nausea/vomiting (46% vs 21%), diarrhea (32% vs 25%), peripheral sensory neuropathy (33% vs 30%) and increased ALT (22% vs 4%). Most common $\geq$grade 3 TRAE was neutropenia in Arm A (43% vs 8% in Arm B). Treatment discontinuation rate due to TRAE was 3%. **Conclusions:** Combination of radium-223 and paclitaxel can be administered safely as most adverse events observed were grade 1 to 2 except for higher incidence of $\geq$ grade 3 neutropenia. The trial did not meet the primary PFS endpoint but there was a numerical improvement observed in median OS with the combination. Clinical trial information: NCT04090398. Research Sponsor: None.

3097 **Poster Session**

AKY-2519, a novel B7-H3-targeted radioconjugate, and its biodistribution profile in patients with mCRPC. First Author: Michael Sathekge, Nuclear Medicine Research Infrastructure, Pretoria, Gauteng, South Africa

Background: AKY-2519 is a 6.1 kDa B7-H3 (CD276) targeting miniprotein with an N-terminal short polyethylene glycol linker and dodecane tetraacetic acid chelator designed to deliver actinium (Ac)-225 for the treatment of patients with metastatic castration-resistant prostate cancer (mCRPC) and other solid tumors. Miniproteins are a novel radioconjugate therapy (RCT) format affording high affinity, selectivity, deep tumor penetration and internalization prolonging tumor retention and rapid plasma clearance limiting exposure to normal tissues. B7-H3 is highly expressed in multiple solid tumor cancers and absent in normal tissues such as salivary glands. These properties render B7-H3 a promising target specifically for Ac-225 delivering RCT in mCRPC. We evaluated biodistribution and tumor uptake of AKY-2519 relative to PSMA-11 and assessed estimated radiation doses to tumors and normal tissues in 16 mCRPC patients. **Methods:** Sixteen mCRPC patients were imaged with [^{68}Ga]Ga-AKY-2519 and [^{68}Ga]Ga-PSMA-11 PET/CTs to assess biodistribution and tumor uptake by SUV. Patients then received low dose [^{177}Lu]Lu-AKY-2519 (~0.37-0.56 GBq) followed by SPECT/CT at 3, 24, and 144 hours post-injection for normal tissue and tumor dosimetry analyses. SPECT images were reconstructed with MIM SPECTRA Recon Software and mean human absorbed dose coefficients (Gy/GBq) were generated with MIM SurePlan MRT. To assess tumor doses, representative lesions including nodal, skeletal and primary disease sites were analyzed across multiple patients. **Results:** No AEs were reported throughout the imaging assessment. PET and SPECT/CTs showed robust tumor uptake with prolonged retention. High lesion concordance was observed between AKY-2519 and PSMA-11 supporting B7-H3 as a novel target in mCRPC and further suggesting co-expression of B7-H3 and PSMA. No accumulation of AKY-2519 was noted in normal tissues with initial activity in the liver rapidly clearing out. Of the normal tissues of interest including kidneys, salivary glands, liver and bone marrow, the mean absorbed doses were below established clinical thresholds when scaled up to a full therapeutic treatment course. The predicted absorbed tumor doses were within expected therapeutic ranges and exceeded normal tissue exposures indicative of a potentially favorable risk-benefit profile for [^{225}Ac]Ac-AKY-2519. **Conclusions:** These are the first clinical data showing concordance between PSMA and B7-H3 on PET-CT imaging in a substantial cohort of patients supporting B7-H3 as a novel target in mCRPC. The normal tissue to tumor dose ratios observed with AKY-2519 suggest a wide therapeutic window as an Ac-225 delivering therapeutic. The low predicted dose to salivary glands supports its use as an actinium delivering RCT for mCRPC, with dosing under IND expected to start in 2H-2026. Research Sponsor: None.

3098 **Poster Session**

First-in-human PET/CT imaging with 68Ga-AKY-2519, a B7-H3 targeted miniprotein radioconjugate, to demonstrate tumor uptake and normal tissue exposure across various advanced solid tumors. First Author: Josephine Enste, Department of Nuclear Medicine, University of Duisburg-Essen, and German Cancer Consortium (DKTK), University Hospital Essen, Essen, Germany

Background: 68Ga-AKY-2519 is a miniprotein radioconjugate developed by Aktis Oncology that targets B7-H3 (CD276) which is overexpressed in several malignancies and is linked with aggressive histology and poor outcomes. AKY-2519 is a high-affinity binder to B7-H3 that internalizes into tumor cells upon binding and thereby maximizes tumor retention. AKY-2519 is also designed to clear rapidly through the kidneys to minimize exposure to normal tissues. To identify potential utility for clinical development of 225Ac-AKY-2519 across various tumor types, here we report the first-in-human evaluation of 68Ga-AKY-2519 using positron emission tomography (PET) in patients with solid tumors. **Methods:** In this prospective, observational study, 18 patients with advanced solid tumors, including prostate cancer (n=7), colorectal cancer (n=4), SCLC (n=3) and NSCLC (n=1) underwent PET/CT imaging following intravenous administration of 68Ga-AKY-2519. Safety, normal tissue distribution and tumor uptake were assessed. Imaging findings were correlated with known disease sites in PSMA and FDG reference PET/CTs as well as available clinical and pathological data. **Results:** 68Ga-AKY-2519 was well tolerated with no adverse events. PET/CT imaging demonstrated favorable tumor uptake, rapid blood pool clearance and low uptake in normal tissues. 68Ga-AKY-2519 uptake (SUVmax) in normal tissues at 120 min post injection (p.i.) was noted in the liver (median 22.9 [interquartile range (IQR) [20.9-30.8]), spleen (7.3 [6.4-11.4]), salivary glands (7.3 [6.4-11.4]), adrenal glands (17.5 [15.9-19.8]) and kidneys (7.3 [6.4-11.4]). No significant bone marrow uptake was noted (median SUVmax 4.1 [3.3-5.1] at 120 min p.i.). High and consistent tumor uptake was observed across various tumor types. The largest cohort was patients with metastatic prostate cancer (n=7), in which the highest 68Ga-AKY-2519 uptake was in bone metastases (median SUVmax 40.4 (120 min p.i.), SUVpeak 25, SUVmean 16.1), followed by lymph node metastases (SUVmax 13.8 (120 min p.i.), SUVpeak 6.5, SUVmean 5.1) and visceral metastases (SUVmax 31.0 (120min p.i.), SUVpeak 22.2, SUVmean 18.7). **Conclusions:** 68Ga-AKY-2519 PET/CT imaging of various malignancies was safe and demonstrated high tumor-to-background uptake and cancerous lesion detection at 120 min p.i. Normal tissue uptake was low, and robust tumor uptake was noted in patients across different solid tumors indicating therapeutic potential. These data warrant further clinical development of 225Ac-AKY-2519. Research Sponsor: None.

Final results of a first-in-human study of the MC1R-targeting radiopharmaceutical ^{225}actinium MTI-201 (^{225}Ac-MTI-201) in metastatic uveal melanoma (mUM). First Author: Nikhil I. Khushalani, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Prognosis in mUM is poor with limited efficacy of currently available therapies. The melanocortin-1 receptor (MC1R) is an attractive target for radiopharmaceutical therapy given high expression in UM. ^{225}Ac-MTI-201 is a novel alpha particle emitting MC1R bound radiopharmaceutical with high biostability, affinity, and MC1R-specific cytotoxicity with defined dosimetry and pharmacokinetics in pre-clinical studies. **Methods:** In this first-in-human study (NCT05496686) of a single IV dose of ^{225}Ac-MTI-201, we enrolled mUM patients (pts) who had disease progression on at least 1 prior therapy. Pts had adequate organ and functional status; prior radiotherapy to >25% of bone marrow was exclusionary. The primary objective was safety and toxicity of ^{225}Ac-MTI-201 with secondary endpoints of pharmacokinetics (PK) and clearance of ^{225}Ac-MTI-201, response rate, progression-free survival (PFS), and overall survival (OS). Up to 12 dose levels [from 4.7 microcurie (μCi) to 1327 μCi] for ^{225}Ac-MTI-201 were planned per a modified continual re-assessment method (CRM) with a cohort size of one based on dose limiting toxicity (DLT) assessment within 28 days of drug administration using CTCAE v5.0. Response was assessed by RECIST 1.1. **Results:** Sixteen pts (8 male, 8 female), median age 63 years (43, 84) have been treated. Median number of prior systemic regimens was 2 (0,4), 8 pts had prior liver directed treatment. Dose of ^{225}Ac-MTI-201 was escalated to level 6 (152 μCi) when one DLT (G4 thrombocytopenia and G4 neutropenia) was observed requiring de-escalation per CRM. A second DLT (G4 neutropenia) at level 5 (76 μCi) required expansions at levels 4 (38 μCi; n=5) and 5 (n=6) where all remaining pts were treated without further DLT with 1 pt currently pending final DLT assessment. Adverse events (AEs) were mostly G1-2 including leucopenia, lymphopenia, neutropenia, thrombocytopenia, anemia, nausea, fatigue and ↑ AST. Reversible myelosuppression [lymphopenia (7), neutropenia (5), thrombocytopenia (2)] was the most common > G3 AE. No non-hematological DLT was seen. Best response was stable disease (4/15; 27%); seen at dose levels 4 and 5. The median PFS was 2.30 months (95% CI: 1.84, 3.65); 6-month PFS was 0.07 (95% CI: 0.0, 0.26) and 12-month OS was 0.39 (95% CI: 0.13, 0.64). Median distribution phase half-life (n=15) was 6.19 minutes followed by a slower median elimination phase half-life of 74.06 minutes with significant positive correlation between fast and slow half-lives (Spearman = 0.696, p= 0.0039), independent of dose level. **Conclusions:** Single dose administration of ^{225}Ac-MTI-201 with dose escalation to 76 μCi appears safe and feasible in mUM. Disease stability in this difficult to treat population is encouraging and a multi-dose study of ^{225}Ac-MTI-201 in mUM is planned pending final pt DLT assessment. ^{225}Ac-MTI-201 has Orphan Drug designation for mUM. Clinical trial information: NCT05496686. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; HHSN261201700035C; Modulation Therapeutics.

First-in-class DIO3 inhibitor as a novel treatment strategy in ovarian cancer. First Author: Sarit Batsir, Dio Tree Ltd, Nazerath, Israel

Background: Ovarian cancer carries high mortality, driven in part by platinum resistance and a scarcity of actionable therapeutic targets. Thyroid hormone signaling via triiodothyronine (T3) exerts tumor-suppressive effects, including inhibition of proliferative and DNA-damage stress pathways. Iodothyronine deiodinase type 3 (DIO3) is a clinically expressed T3-inactivating enzyme associated with aggressive disease biology, therapeutic resistance, and poor patient outcomes. DioTree Ltd is the first biotech company that developed ITYR-DBRMD, a first-in-class small-molecule DIO3 inhibitor for cancer treatment. **Methods:** DIO3 target engagement was evaluated using enzymatic mimic assays, intracellular T3 quantification (ELISA), and cellular thermal shift assays (CETSA). Pharmacokinetics (PK) were characterized across clinically relevant delivery routes (IV, IP, SC) with development of a dedicated bioanalytical quantification method. Antitumor efficacy was tested in nude mice bearing homologous recombination-proficient (HRP), carboplatin-resistant ovarian cancer xenografts. Mice received vehicle, ITYR-DBRMD, carboplatin, or their combination for three weeks. Tumor growth inhibition (TGI) and safety were assessed. **Results:** ITYR-DBRMD achieved selective and durable inhibition of DIO3 activity with direct cellular binding confirmation, robust increases in intracellular T3 levels, and consistent PK exposure across all administration routes tested. Monotherapy TGI was 43% for carboplatin and 50% for ITYR-DBRMD. Combination therapy produced a clinically meaningful efficacy increase, reaching 68% TGI, with no observed treatment-related toxicity or weight loss, supporting a favorable therapeutic index. Albumin-based tumor delivery and drug retention in tumors was established. **Conclusions:** These data support advancement of ITYR-DBRMD toward early-phase clinical testing, with potential application in ovarian cancer patients, a population lacking targeted therapeutic options. Research Sponsor: Israel Innovation Authority and NGT Incubator.

EIK1003, a PARP1-selective inhibitor, in combination with paclitaxel (PTX): Initial combination and updated monotherapy results from a phase 1/2 study EIK1003-001 in advanced solid tumors. First Author: Martin Hojgaard, Rigshospitalet, Copenhagen, Denmark

Background: Non-selective PARP inhibitors (PARPi) demonstrate efficacy in HRR-mutant tumors but cause myelosuppression, potentially mediated by PARP2 inhibition. Overlapping hematologic toxicities have limited PARPi combinations with chemotherapy, restricting their use largely to the maintenance setting. EIK1003 is a potent and selective PARP1 inhibitor that may enable chemotherapy combinations previously not feasible. Here we report the first clinical data for EIK1003 + PTX and updated results for EIK1003 monotherapy. **Methods:** Cohort 1C evaluated EIK1003 QD (dose level [DL] 1 to 4) + PTX 80 mg/m² QW (Days 1, 8, 15 of 21-day cycles) in patients (pts) with platinum-resistant recurrent ovarian cancer (OC) and HER2(-) breast cancer (BC). Cohort 1A evaluated EIK1003 monotherapy (10 to 160 mg QD). BOIN dose escalation design was used. Primary endpoints were safety and tolerability; secondary endpoints were PK and antitumor activity. **Results:** As of 21-Nov-2025 safety data cutoff, 51 patients were treated in Cohort 1C; 30 remain on treatment. Median age was 59 years (range 25-81), ECOG PS 0/1 (54.9%/43.1%), and 62% pts received ≥ 4 prior lines of therapy. One DLT of febrile neutropenia was reported at DL4. Gr ≥ 3 TEAEs occurred in 62.7% pts and were mainly hematologic (Table 1). All pts with Gr ≥ 3 anemia had baseline anemia. TEAEs led to dose reduction in 10 pts and discontinuation in 8 pts. No deaths occurred due to TEAEs. The ORR was 23.1% (1 CR, 8 PR), with responses in OC (n=5) and BC (n=4). EIK1003 PK in combination was consistent with monotherapy, with target concentrations achieved at all dose levels. In Cohort 1A, 65 pts were treated. Gr ≥ 3 TEAEs were 43.1%, with anemia and neutropenia being most common (Table 1). 3/6 pts with Gr ≥ 3 anemia had baseline anemia. ORR was 14.3% overall, and 31.3% (5/16) in PARP-naïve pts. Median DOR in confirmed responders was > 6 mos in both cohorts (Table 1). Safety, PK/PD, and preliminary efficacy supported advancement of two doses into Part 2 dose optimization. **Conclusions:** EIK1003 + PTX demonstrated a tolerable safety profile in a heavily pre-treated population, with hematologic toxicities comparable to historical PTX use (eg, KN-B96, ESMO 2025). These findings represent the first clinical evidence that PARP1-selective inhibitors can be safely combined with chemotherapy. Extended follow-up of EIK1003 monotherapy confirms durable tolerability with antitumor activity. Clinical trial information: NCT06253130. Research Sponsor: None.

Safety and efficacy summary.

	Cohort 1C (EIK1003 + PTX)	Cohort 1A (EIK1003 monotherapy)

Tucatinib + subcutaneous (SC) trastuzumab (Tuc + Trast SC) in patients (pts) with solid tumors with *ERBB2* alterations (alts): Results from the targeted agent and profiling utilization registry (TAPUR) study. First Author: Tareq Al Baghdadi, Michigan Cancer Research Consortium, IHA Hematology Oncology, Ypsilanti, MI

Background: TAPUR is a phase II basket study evaluating the antitumor activity of commercially available targeted agents in pts with advanced cancers with specific genomic alts. Combined results of four cohorts of pts with solid tumors with *ERBB2* alts treated with Tuc + Trast SC are reported. **Methods:** Eligible pts had measurable disease, ECOG performance status (PS) 0-2, adequate organ function, and no standard treatment (tx) options. Genomic testing was done in CLIA-certified, CAP-accredited labs. Dosing was 300 mg of Tuc given orally twice daily, 600 mg of Trast and 10,000 units of hyaluronidase SC every 3 weeks (wks), until disease progression. Primary endpoint was disease control (DC) per investigator definition as complete (CR) or partial (PR) response or stable disease (SD) of at least 16 wks duration (SD16+) per RECIST v.1.1. The hypothesized null DC rate of 15% was rejected if the lower limit of a 1-sided 90% CI was >15%. Inferences were based on a beta-binomial model, which accounts for tumor type variance. Secondary endpoints were progression-free survival (PFS), overall survival (OS), objective response (OR), duration of response, duration of SD (DOSD), and safety. **Results:** 78 pts (histology-pooled [n=40], lung [n=16], biliary tract [n=11], uterus [n=11]) with 21 tumor types with *ERBB2* alts (*ERBB2* amplification [amp], n=38; mutation [mut], n=32; mut and amp, n=6; overexpression [OE], n=2) were enrolled. All cohorts were combined for analysis. 3 pts were not evaluable. Table shows demographics and outcomes. 1 CR (urothelial carcinoma [UC], *ERBB2* mut), 6 PR (uterus [2], esophagus [1], lung, neuroendocrine [1], ovary [1], UC [1]; *ERBB2* amp [5], mut [1]) and 18 SD16+ (10 tumor types; *ERBB2* amp [7], mut [10], OE [1]) were observed for a DC rate of 33% (1-sided 90% CI, 27 to 100) and an OR rate of 9% (95% CI, 4 to 18). The null hypothesis was rejected. Duration of CR in 1 pt was 87 wks. Median (med) duration of PR was 12 wks (range, 6-72). Med DOSD in pts with SD16+ was 28 wks (range, 12-57). 20 pts (26%) had ≥1 grade 3 tx-related AE or SAE. All were consistent with tx label except back pain, cardiac troponin increase, chronic kidney disease, heart failure, hypomagnesemia, hypophosphatemia, pericardial and pleural effusion, peripheral motor and sensory neuropathy, sinus tachycardia, systemic inflammatory response syndrome and UTI. **Conclusions:** Tuc + Trast SC demonstrated antitumor activity in pts with advanced solid tumors with *ERBB2* alts, warranting additional study. Clinical trial information: NCT02693535. Research Sponsor: Genentech; Pfizer, Seagen (now a wholly owned subsidiary of Pfizer Inc.); AstraZeneca, Bayer, Boehringer Ingelheim, Bristol Myers Squibb, Eli Lilly and Company, Merck, Taiho Oncology.

Phase II basket trial of brigatinib for *ALK* fusion–positive solid tumors: ALLBREAK trial (WJOG15221M). First Author: Tomoki Sakakida, Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan

Background: *ALK* fusions occur in approximately 0.2% of solid tumors other than non-small cell lung cancer (NSCLC) and are associated with poor outcomes. Prospective evidence for ALK tyrosine kinase inhibitors in this rare condition is limited. **Methods:** This phase II basket trial evaluated brigatinib (90 mg once daily for 7 days, then 180 mg once daily) using a decentralized clinical trial platform. Eligible patients had advanced solid tumors other than NSCLC with *ALK* fusions detected in tumor tissue or circulating tumor DNA (ctDNA). The initial planned sample size was 14, with an objective response rate (ORR) of 50% considered promising and 12% unacceptable (one-sided α = 0.025; β = 0.09). Enrollment was expanded to 28 patients due to rapid accrual. ctDNA analyses were performed at baseline, cycle 2, and progressive disease (PD). **Results:** Twenty-eight patients from ten hospitals were enrolled from May 2022 to March 2025; one was excluded from the full analysis set (FAS) due to clinical deterioration before treatment initiation. The FAS (n = 27) included patients with biliary tract cancer (BTC), colorectal cancer (CRC), thyroid cancer (TC), inflammatory myofibroblastic tumor (IMT), or other solid tumors (n = 7, 5, 3, 3, and 9, respectively). ECOG PS was 0 or 1 (18/9). The number of prior lines of therapy was 0–2 and ≥3 in 20 and seven patients, respectively. *ALK* fusions were detected by next-generation sequencing (NGS) or fluorescence in situ hybridization (22/5). Among NGS-detected cases, fusion partners included *EML4* (n = 8), *STRN* (n = 2), and others (including *CEP44*, *HOOK1*, *TPM3*, and *RRBP1*; n = 12). The confirmed ORR in the FAS was 63.0% (95%CI, 42.4–80.6), with ORRs of 57% in BTC, 60% in CRC, and 67% each in TC, IMT, and other tumors. For the first 14 patients enrolled as per initial study design, the ORR was 57.1% (95% CI, 28.9–82.3%). In the FAS, the disease control rate was 92.6%, and the median progression-free survival, duration of response, and overall survival were 9.7, 14.4, and 19.5 months, respectively. At data cutoff, 11 patients remained on treatment. ORR varied with fusion partner: 38% for *EML4*, 100% for *STRN,* and 75% for other partners. ORR was comparable between patients with and without baseline ctDNA detection of *ALK* fusions (67% vs. 64%). At PD, acquired *ALK* mutations (G1202R, E1028K, and L1502L) were detected in 23% (3/13) of patients; alterations in *EGFR, KRAS,* or *MET* were observed in 23% (3/13) of patients. The most common grade 3–4 adverse events were increased creatine phosphokinase (11%) and hypertension (11%). Interstitial lung disease occurred in 7% of patients (grade 1 only; no grade 3–4). No treatment-related deaths occurred. **Conclusions:** Brigatinib shows a high, durable response rate and manageable toxicity in non-NSCLC *ALK* fusion–positive solid tumors, supporting its use as a tumor-agnostic therapeutic agent in this rare molecular subset. Clinical trial information: jRCT2041210148. Research Sponsor: Takeda.

Zongertinib combined with T-DXd in HER2-positive metastatic gastric, gastroesophageal junction, or esophageal carcinoma (mGEAC): First results from a phase Ib/II dose-escalation trial. First Author: Izuma Nakayama, National Cancer Center Hospital East, Kashiwa, Chiba, Japan

Background: Zongertinib, an irreversible TKI, selectively inhibits HER2 while sparing wild-type EGFR, thereby minimizing associated toxicities. Beamion BCGC-1 (NCT06324357) is an ongoing Phase Ib/II multicohort trial investigating zongertinib, as monotherapy or combined with other agents, in HER2-positive metastatic breast cancer, metastatic colorectal cancer, and mGEAC. Here, we report the first data from Cohort C (Phase Ib), in which patients (pts) with HER2-positive mGEAC received zongertinib combined with T-DXd, as well as supporting preclinical data. **Methods:** Preclinical activity of zongertinib plus T-DXd was assessed in xenograft mouse models of HER2-positive gastric cancer. In Cohort C, pts with histologically/cytologically confirmed, unresectable, HER2-positive mGEAC were enrolled. Pts had documented HER2-positive disease (overexpression/amplification) and disease progression following HER2-directed treatment. Pts received escalating doses of zongertinib once-daily plus a fixed dose of T-DXd (6.4 mg/kg) every three weeks. Dose escalation was guided by a BLRM with overdose control. Pts remained on treatment until any protocol-defined stopping criterion occurred. The primary endpoint was the occurrence of DLTs during the MTD evaluation period. Secondary endpoints included further safety assessments and objective response (investigator-assessed; RECIST v1.1). **Results:** In mouse models, the addition of zongertinib to T-DXd led to increased antitumor activity. In Beamion BCGC-1, as of November 4, 2025, 19 pts had been enrolled to Cohort C and received zongertinib 60 mg (n=4), 120 mg (n=9), 240 mg (n=4), or 300 mg (n=2). Median age was 63 years, 74% male, 74%/26% ECOG PS 0/1. All pts had received prior trastuzumab-based therapy. Treatment-emergent adverse events (TEAEs; any grade [G]/G≥3) were reported in 17/9 (89%/47%) pts. AEs related to zongertinib (any G/G≥3) were reported in 13/2 (68%/11%) pts. There were no zongertinib-related G4/5 AEs. The most-common TEAEs (any G/G≥3) were nausea (53%/0%), decreased appetite (47%/5%), and diarrhea (47%/0%). One pt each had G1 pneumonitis and interstitial lung disease; both recovered. AEs leading to zongertinib dose reduction/discontinuation were reported in 1/2 pts. AEs leading to T-DXd dose reduction/discontinuation were reported in 8/1 pts. The first confirmed responses to zongertinib combined with T-DXd were observed across the different zongertinib dose levels (60 mg: 1 CR, 2 PR; 120 mg: 2 PR, 5 SD; 240 mg: 1 PR, 1 SD). **Conclusions:** No new safety signals were observed for zongertinib in combination with T-DXd; further dose escalation is ongoing. Encouraging clinical activity was observed in pretreated pts with HER2-positive mGEAC who had disease progression following prior trastuzumab-based therapy. Clinical trial information: NCT06324357. Research Sponsor: Boehringer Ingelheim.

Early results from the first-in-human phase 1 study of WEE1 inhibitor APR-1051 in patients with advanced solid tumors (ACESOT-1051). First Author: Shiraj Sen, NEXT Oncology Dallas, Dallas, TX

Background: WEE1 tyrosine kinase regulates cell cycle checkpoints (G1-S, G2-M) and DNA damage responses. Inhibiting WEE1 can force premature mitotic entry and subsequent apoptosis. APR-1051 is a highly potent, orally bioavailable WEE1 inhibitor (WEE1i) with *in vivo* anti-proliferative activity. Low off-target inhibition of APR-1051 on PLK kinases (PLK1, PLK2, PLK3) differentiates it from other WEE1i's and may confer improved safety. **Methods:** This open-label dose escalation (BOIN) and dose selection optimization study is evaluating APR-1051 using a once-daily (QD) regimen. The study is currently enrolling at 220 mg at three US sites (NCT06260514). Primary study objectives are to characterize the safety, dose-limiting toxicity (DLT), maximum tolerated dose/maximum administered dose, and recommended phase 2 dose of APR-1051. Secondary objectives include evaluating APR-1051 pharmacokinetic properties and preliminary efficacy (RECIST v1.1; PCWG3 criteria for mCRPC). Key inclusion criteria are age ≥ 18 years with advanced solid tumor and cancer-associated gene alterations, prior standard-of-care systemic treatment, and ECOG PS 0 or 1. Key exclusion criteria are prior WEE1i use, CNS metastases/unstable involvement, secondary malignancies requiring therapy, and concomitant moderate/strong inhibitors/inducers of CYP3A4/5, MDR1, or BCRP. **Results:** As of January 16, 2026, 22 patients (median age 62 years [range: 40–86]; have been enrolled up to the 220 mg dose level. Most (n=13, 59%) cases were colorectal cancers (colon [n=9, 41%], rectal [n=4, 18%]) followed by uterine (n=3, 14%), pancreatic (n=2, 9%), and breast, gastric, oropharyngeal, and soft tissue cancer (each n=1, 5%). The median prior lines of treatments was 3. Any grade adverse event (AE) was report in 21 (95%) patients. Treatment-related AEs were reported in 12 (55%) patients; 10 (45%) patients had non-serious gastrointestinal events. Twelve (55%) patients had 18 unique serious AEs, including one death on treatment unrelated to APR-1051 and one DLT of grade 3 elevated liver enzymes (AST, ALT) probably related to APR-1051 (n=1, 5%). Antitumor activity was observed in one (5%) patient with uterine serous carcinoma treated with APR-1051 150 mg who had an unconfirmed partial response—50% reduction in target lesion size (RECIST v1.1) and > 90% reduction in CA-125 tumor marker—at per protocol 8-week assessment. Five (23%) patients had stable disease: oropharyngeal cancer (APR-1051 70 mg [n=1, 5%]); colon, rectal, uterine cancer (100 mg [n=3, 14%]); colon cancer (150 mg [n=1, 5%]). A dose proportional increase in exposure was observed. **Conclusions:** In the ongoing trial, continuous, oral APR-1051 QD has a manageable safety profile with preliminary signals of antitumor activity in patients with pretreated advanced solid tumors. Clinical trial information: NCT06260514. Research Sponsor: Aprea Therapeutics.

Zidesamtinib efficacy and safety in patients with advanced *ROS1*-positive solid tumors other than NSCLC in the ARROS-1 study. First Author: Benjamin J. Solomon, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: *ROS1* fusions are oncogenic drivers in various cancers. Multiple ROS1 tyrosine kinase inhibitors (TKIs) are available for *ROS1*+ non-small cell lung cancer (NSCLC); however, there are limited data on the activity of these agents in patients with other *ROS1*+ tumors. In patients with advanced *ROS1*+ NSCLC (TKI pretreated and TKI-naïve), zidesamtinib has demonstrated encouraging clinical activity, including in patients with CNS disease and/or ROS1 G2032R mutation, and a safety profile consistent with its highly ROS1-selective, TRK-sparing design. Here we report the first data on the activity of zidesamtinib in patients with other *ROS1*+ solid tumors. **Methods:** The global Phase 1/2 ARROS-1 study (NCT05118789) includes a cohort of patients with advanced/metastatic *ROS1*+ solid tumors other than NSCLC, whose disease has progressed on any prior therapy. Key endpoints are objective response rate (ORR, RECIST v1.1 by BICR), duration of response (DOR), and safety. Data cut: 22 September 2025. **Results:** 15 efficacy-evaluable patients with *ROS1*+ solid tumors (10 non-NSCLC tumor types) received zidesamtinib. Patients received a median of 2 prior anticancer therapies (range 1-6): 60% were ROS1 TKI-naïve, 40% were ROS1 TKI pre-treated (range 1-2), 73% had prior chemotherapy (range 1-4). ORR was 40% (6/15, including 1 PR pending confirmation), with no disease progression by BICR among responders (DOR range 3.9+ – 22.8+ months). Responses were observed across multiple tumor types, including cholangiocarcinoma, colorectal, gastric, inflammatory myofibroblastic tumor, ovarian, and pancreatic. 2 ROS1 TKI pre-treated patients had ROS1 resistance mutations (G2032R and F2004I/F2004V) at baseline and both achieved a PR (1 pending confirmation). Treatment-related adverse events (TRAEs) in ≥15% of patients were increased alanine aminotransferase, increased blood creatine phosphokinase, and dysgeusia (n=3 patients each). No patients discontinued due to TRAEs; 1 pt dose-reduced due to TRAE. **Conclusions:** Zidesamtinib demonstrated encouraging activity in patients with diverse *ROS1*+ solid tumors, including those refractory to standard-of-care therapies. Safety was consistent with its ROS1-selective, TRK-sparing design. Enrollment is ongoing. Clinical trial information: NCT05118789. Research Sponsor: Nuvalent, Inc.

First-in-human phase 1/2 study of ETX-19477, an oral, potent, and selective PARG inhibitor, in patients with advanced solid tumors (ERADIC8). First Author: Ezra Rosen, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Poly(ADP-ribose) glycohydrolase (PARG) is an enzyme that catalyzes the removal of poly-ADP-ribose (PAR) chains from proteins during DNA damage repair. PARG inhibition leads to selective cell death in tumors with underlying replication fork defects, including BRCAm tumors, through a mechanism distinct from PARP inhibition. ETX-19477 is an oral, potent, and selective PARG inhibitor that shows robust preclinical activity in mouse models of ovarian, breast, and gastric cancers. **Methods:** ERADIC8 is an open-label, multicenter, Phase 1/2 study, consisting of two parts, dose escalation and dose expansion. A Bayesian Optimal Interval Design was used to enroll patients (pts) into dose escalation cohorts, with enrichment for pts with BRCAm high grade serous ovarian (HGSOC) and breast cancers. The primary objective is to assess safety/tolerability of ETX-19477 and define the maximum tolerated dose (MTD) and recommended Phase 2 dose(s). Secondary and exploratory objectives include pharmacokinetics, pharmacodynamics, and preliminary anti-tumor activity per RECIST v1.1. ETX-19477 is given orally once or twice daily in 21-day cycles. **Results:** As of Jan 6 2026, 45 pts were enrolled into the study across 11 dose levels (range: 80-750 mg QD, 190-350 mg BID). Tumor types included ovarian (n=24, BRCAm: 18), breast (n=8, BRCAm: 7), endometrial (n=6, BRCAm: 0), colorectal (CRC, n=3, BRCAm: 1), and other (n=4, BRCAm: 0) cancers. Treatment-related AEs (TRAEs; any grade) occurring in >20% of pts were nausea (53%), vomiting (38%), and fatigue (24%). The only Gr3 TRAE occurring in >5% of pts was neutropenia (16%). There was one Gr4 TRAE of neutropenia in 1 pt (2%) and no Gr5 TRAEs. ETX-19477 exposure is dose proportional, and the BID regimen achieves >85% PARG inhibition throughout the dosing interval in a blood-based PAR accumulation pharmacodynamic assay. As of the data cutoff, dose escalation is ongoing at 350 mg BID (MTD has not been defined) and dose expansion is ongoing at 200-300 mg BID. Among BRCAm, HGSOC pts enrolled at BID dose levels, there were 7 evaluable pts with a median of 4 prior lines of therapy (range 2–11): 2 pts achieved a partial response (PR, 29%) and 3 pts achieved stable disease (SD, 43%). Both pts with PRs were platinum-resistant and received prior PARP inhibitor treatment. 1 pt with BRCAm CRC remains on active therapy (250 mg BID) with SD for 7 months. **Conclusions:** ETX-19477 was well tolerated and showed anti-tumor activity in heavily pretreated pts with BRCAm, platinum-resistant HGSOC during dose escalation. These findings provide the first clinical proof-of-concept of PARG inhibition in HGSOC. ETX-19477 is being further evaluated in the dose expansion phase of the study. Clinical trial information: NCT06395519. Research Sponsor: 858 Therapeutics.

Final analysis of KOMET (NCT04924608), a phase 3 study of selumetinib in adults with NF1-PN. First Author: Alice P. Chen, Developmental Therapeutics Clinic, Division of Cancer Treatment and Diagnosis, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: In 2025 the EMA and FDA expanded the approval of selumetinib (SELU; ARRY-142886, AZD6244) to adults with neurofibromatosis type 1 (NF1) and symptomatic, inoperable plexiform neurofibromas (PN). We report the final exploratory analysis of SELU efficacy and safety from the Phase 3, randomized, double-blind, placebo (PBO)-controlled KOMET trial. **Methods:** Adults (≥18 yrs) with NF1-PN were randomized 1:1 to 28-day cycles of oral SELU 25 mg/m^2 BID or PBO with crossover to SELU at the end of Cycle (C) 12 or earlier if radiological progression was confirmed by independent central review (ICR). The single-arm objective response rate (ORR) by use of volumetric MRI analysis per ICR REiNS and safety were exploratory endpoints at final DCO (last participant (pt) completed C24; 17 Mar 2025)). Pharmacokinetics (PK) data were collected at steady state C1, Day (D) 8. A planned sample of 73 pts per arm with a 2-sided 5% alpha Fisher's exact test had >99% power to detect the difference between a SELU ORR of 20% and PBO ORR of 0%. **Results:** Overall, 145 pts (SELU: 71; PBO: 74) were randomized; 66 pts in the PBO group crossed over to SELU treatment for the open-label period (SELU period). In the SELU period, 137 pts were treated; 96 pts (66.2%) (SELU: 45, PBO/SELU: 51) completed the study and were judged by the investigators at DCO to have clinical benefit at study completion and, consequently, continued receiving SELU during the post-trial access program. Median actual exposure to SELU during the SELU period was 554 days and maximum exposure to SELU treatment was 1156 days. The median relative dose intensity of SELU treatment was 99.5%. The ORR in the SELU group (N = 71) was 23.9% (95% CI; 14.6, 35.5). Of the 17 pts who achieved objective response, 10 (58.8%) remained in response for ≥12 months while 5 pts (29.4%) had not yet reached 12 months follow-up from onset of response. Median duration of response was not reached in the SELU group by final analysis. During the SELU period (N = 137), 51 pts (37.2%) had a maximum AE severity of ≥Grade 3 (most frequent were known SELU AEs); ≥1 AEs, possibly related to SELU, were experienced by 127 pts (92.7%); of these, 31 pts (22.6%) had ≥Grade 3 AEs. Serious AEs (SAEs) were experienced by 24 pts (17.5%); 6 pts (4.4%) had SAEs possibly related to SELU. AEs of special interest were experienced by 85 pts (62.0%); increased blood creatine phosphokinase (43.1%), increased ALT/AST (13.9% each), and peripheral edema (13.1%) were the most frequent (≥10% of pts). AEs were manageable; the AE-related discontinuation rate for the trial was 9.5%. At C1 D8, 64 pts who received SELU were included in the PK Analysis Set. Median t_{max} was 1.5 h and geometric mean $AUC_{(0\text{-}12)}$ was 2986 h × ng/mL for SELU. **Conclusions:** In the first international, randomized, PBO-controlled trial in adults with NF1-PN, SELU achieved a sustained and durable, clinically meaningful reduction in PN volume per ICR REiNS. No new safety concerns were identified and AEs were manageable. Clinical trial information: NCT04924608. Research Sponsor: AstraZeneca as part of an alliance between AstraZeneca and Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA (MSD).

First-in-human trial of the TEAD inhibitor ODM-212 in patients with advanced solid tumors (TEADES). First Author: Johann S. De Bono, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom

Background: The Hippo pathway is implicated in multiple human cancers including mesothelioma and epithelioid hemangioendothelioma (EHE). When Hippo signalling is inactive, Yes-associated protein 1 (YAP1) and WW-domain-containing transcription regulator 1 (TAZ) locate to the nucleus, activating TEA domain family member (TEAD) transcription factors (TEAD1-4) to impact transcription and key oncogenic cellular processes. ODM-212 is a small molecule oral pan-TEAD inhibitor with *in vitro* and *in vivo* antitumour activity in solid tumours. **Methods:** TEADES is a multi-site, open-label, first-in-human trial of ODM-212 enrolling patients ≥18 years of age with various types of advanced, metastatic solid tumours where the Hippo pathway is implicated, with or without relevant genetic alterations. The study followed a Bayesian optimal interval (BOIN) design with a dose escalation with backfill cohorts, followed by expansion in tumour types of interest. Main objectives were safety (including dose-limiting toxicity (DLT)), preliminary efficacy and pharmacokinetics. ODM-212 was administered orally, once or twice daily, in a continuous 4-week cycle. **Results:** Between 7 November 2023 and 5 January 2026, 76 patients (mesothelioma 29, EHE 15, other 32) of mean age 62.1 years and all ECOG 0-1 received ODM-212 at doses between 20-320 mg/day, with 44 continuing on treatment at time of data cut-off. Previous treatment included checkpoint inhibitors (N=38), chemotherapy (N=59) or both (N=36). The longest exposure at data cut-off was 18-months. ODM-212 was well tolerated. No DLTs were reported and the maximum tolerated dose (MTD) was not identified. The most frequent treatment-related adverse event (TRAE) was proteinuria (19.7%), which was reversible and resulted in treatment adjustment in 6 (7.9%) patients. Other common TRAE's were increased lipase (15.8%) and nausea (10.5%). Grade ≥3 TRAE's occurred in 6.6% patients (anemia and increases in amylase, lipase, alanine aminotransferase and aspartate aminotransferase). Treatment responses by RECIST 1.1 were observed across multiple doses (ORR 7/45 = 15.6%), predominantly in patients with mesothelioma (ORR 27.8% in 18 evaluable patients, disease control rate (DCR) 77.8%) and EHE (ORR 22.2% in 9 evaluable patients, DCR 100%). ODM-212 demonstrated a predictable pharmacokinetic profile, with steady state achieved by 15 days and mean elimination half-life of 1-2 days, supporting once or twice daily dosing. **Conclusions:** ODM-212 administration to extensively treated patients with advanced cancer was well tolerated and resulted in some promising tumour responses (particularly in mesothelioma and EHE). The phase 2 portion of TEADES is currently enrolling patients. Clinical trial information: NCT06725758. Research Sponsor: Orion Pharma.

3112 Poster Session

HRS-5041, an androgen receptor degrader, in metastatic castration-resistant prostate cancer: A phase 1, multicenter, first-in-human study. First Author: Wei Xue, Shanghai Jiao Tong University School of Medicine Renji Hospital, Shanghai, China

Background: ADT plus NHA have been approved for PC of different stages. However, patients (pts) inevitably develop drug resistance, and AR mutations are a common cause of this resistance. HRS-5041 is a novel, oral, highly effective AR degrader that specifically targets the AR wild type (AR WT) and clinically relevant AR LBD mutants. We conducted a phase 1 trial to assess HRS-5041 in NHA-resistant mCRPC. **Methods:** Pts with mCRPC who had progressed on ≥1 NHA and ≥1 taxane chemo (unless refused or not indicated to chemo) were eligible. Pts orally received HRS-5041 at 30–540 mg QD or 240–300 mg BID during dose-escalation (DE), followed by dose or indication expansion at 180–360 mg QD or 240-300 mg BID. 240 mg BID and 360 mg QD were selected for dose optimization. The primary endpoints were DLT, MTD, and RP2D. **Results:** As of Dec. 12, 2025, 156 pts were enrolled, including 77 with AR-LBD mutation and 79 with AR-LBD WT. During DE, no DLT occurred. MTD was not reached. TRAEs were reported in 133 (85.3%) pts; the most common were anemia (38.5%), decreased appetite (25.6%), and diarrhea (24.4%). Grade ≥3 TRAEs and serious TRAEs occurred in 20 (12.8%) and 4 (2.6%) pts. No TRAEs led to death. Among all evaluable pts, rate of PSA reduction ≥50% was 0 for 1 pt at 30 mg QD, 0 for 4 pts at 90 mg QD, 17.4% for 23 pts at 180 mg QD, 32.1% for 53 pts at 360 mg QD, 40.0% for 5 pts at 540 mg QD, 35.7% for 56 pts at 240 mg BID, and 11.1% for 9 pts at 300 mg BID. Data by AR-LBD status for expanded doses are shown in table. Both 360mg QD and 240mg BID groups showed excellent PSA response rates and rPFSs, regardless of AR-LBD status. Among pts with AR-LBD mutations, the 240 mg BID group showed a superior rate of PSA reduction ≥50% and a higher 8-month rPFS rate than the 360 mg QD group. Notably, 2 patients in the 240 mg BID group achieved CR, including 1 with liver metastases. **Conclusions:** HRS-5041 showed tolerable safety and promising antitumor activity in pretreated mCRPC. A phase 3 study is currently underway in mCRPC pts with AR-LBD mutation, with a recommended dose of 240mg BID. Clinical trial information: NCT05942001. Research Sponsor: None.

Safety and efficacy of ifebemtinib (IN10018) combined with garsorasib (D-1553) in KRAS^{G12C} mutant solid tumors from a phase Ib/II study: 2-year follow-up from single-arm of non-small-cell lung cancer (NSCLC). First Author: Yanling Wang, Zhejiang Cancer Hospital, Hangzhou, China

Background: Studies have shown that combining RAS inhibitors (RASi) with appropriate partners may enhance efficacy. Ifebemtinib (ifebe) is a potent and selective oral focal adhesion kinase (FAK) inhibitor demonstrating synergy with RASi. D-1553 is a KRAS^{G12C} inhibitor approved in China for KRAS^{G12C}–mutant NSCLC. We previously reported encouraging antitumor activity with ifebe plus D-1553. Here we present updated 2-year efficacy and safety results, including exploratory TP53 subgroup analyses. **Methods:** This is a phase Ib/II, open-label study to evaluate the safety, tolerability, pharmacokinetics, and antitumor activity of D-1553 in combination with ifebe in patients with locally advanced or metastatic NSCLC harboring KRAS^{G12C} mutations regardless of PD-L1 expression. Patients received ifebe 100 mg once daily (QD) plus D-1553 600 mg twice daily (BID). **Results:** As of January 4, 2026, 33 treatment-naïve NSCLC patients (81.8% stage IV) were enrolled; median follow-up was 24.9 months (Range: 1.05, 31.77). The objective response rate (ORR) was 90.3% (95% CI: 74.2, 98.0) and disease control rate (DCR) was 96.8% (95% CI: 83.3, 99.9). The median progression free survival (PFS) was 22.14 months (95% CI: 9.63, NE) with the 12- and 24-month PFS rates were 67.9% and 40.0%, respectively. The median duration of response (DOR) was 19.38 months (95% CI: 12.85, NE). The 24-month overall survival (OS) rate was 69.7%, and mOS was not reached (95% CI: 27.76, NE). TP53 wild-type patients (n=17) showed more favorable outcomes, with higher ORR (94.1% vs. 81.8%), unreached mPFS (vs. 14.2 months), and unreached mOS (vs. 17.7 months) compared with TP53-mutant patients (n=13). The safety profile of ifebe plus D-1553 was generally comparable to that of each single agent. SAEs were reported in 33.3% of patients, with 18.2% experiencing ifebe-related SAEs. Most TRAEs were grade 1–2; grade ≥3 TRAEs occurred in 24.2% of patients, including one grade 4 event. No treatment-related deaths or discontinuations were reported. **Conclusions:** Ifebe plus D-1553 exhibited robust, durable antitumor activity and a favorable safety profile in treatment-naïve KRAS^{G12C}-mutant NSCLC patients regardless of PD-L1 expression. Notably, TP53-wild-type KRAS^{G12C} tumors typically show poor responsiveness and short durability to ICI therapies, likely due to reduced PD-L1 expression and lower tumor mutational burden. The superior outcomes in TP53 wild-type patients suggest this combination may address an unmet need in this distinct population. Further studies are needed to validate these findings and define the regimen's optimal role in the evolving treatment landscape. Clinical trial information: NCT06166836; NCT05379946. Research Sponsor: None.

3114 Poster Session

First-in-human phase I/II study of a highly selective FGFR2 inhibitor 3HP-2827 in patients with advanced solid tumors harboring *FGFR2* alterations. First Author: Jiajia Yuan, Department of Gastrointestinal Oncology, Peking University Cancer Hospital, Beijing, China

Background: Molecular profiling of cholangiocarcinoma (CCA) is highly recommended to guide access to targeted therapies such as FGFR2 inhibitors. 3HP-2827 is a highly selective and potent FGFR2 inhibitor targeting FGFR2 alterations. Here we report the findings of 3HP-2827 in advanced solid tumors harboring FGFR2 alterations. **Methods:** This is a phase I/II study to evaluate the safety, tolerability, PK, and preliminary efficacy of 3HP-2827 in pts with advanced solid tumors harboring FGFR2 alterations. Pts failed to standard therapy with/without prior pan-FGFR inhibitor (FGFRi) are eligible for enrollment. Bayesian Optimal Interval (BOIN) and back filling design were employed in the dose-escalation stage of phase I, followed with the expansion stage. Treatment-related adverse events (TRAEs), PK, and anti-tumor activity (RECIST v1.1) were assessed. **Results:** As of Jan 8, 2026, a total of 52 pts (46 with CCA, 6 with others) were enrolled from 12 centers, received 3HP-2827 at doses of 60-180 mg once daily (QD), including 42 with FGFR2 fusion/rearrangement (f/r), 6 with FGFR2 mutation. 19 pts (36.5%) had prior FGFRi. No dose-limiting toxicities (DLTs) were observed at the dose levels of 60 mg, 120 mg, 180 mg QD. 3HP-2827 had favorable PK with doses≥120 mg QD providing FGFR2 occupancy > 90%. The most common TRAEs were FGFR2 on-target toxicities including dry mouth (69.2%, G3 1.9%), nail toxicity (67.3%, G3 3.8%), stomatitis (50%, G3 3.8%), dry eyes (26.9%, G3 1.9%), PPE (19.2%, G3 3.8%). 12 pts (23.1%) experienced at least one G3/G4 TRAE and no G5 TRAEs occurred. 7 pts (13.5%) experienced at least one serious adverse event, 4 (7.7%) of them were considered related to 3HP-2827. No discontinued treatment or death due to TRAEs. Anti-tumor activities were observed from 60 mg QD. Among 15 CCA pts (FGFR2 f/r, FGFRi-naive) who had at least one post-treatment tumor assessment, objective response rate (ORR) was 80% (95% CI: 51.9, 95.7), and disease control rate (DCR) was 100% (95% CI: 78.2, 100). The ORR and DCR in 15 CCA pts (FGFR2 f/r, FGFRi-refractory) was 26.7% (95% CI: 7.8, 55.1) and 86.7% (95% CI: 59.5, 98.3). The ORR and DCR in 4 advanced solid tumor pts (FGFR2 mutation, FGFRi-naive) was 75% (95% CI: 19.4, 99.4) and 100% (95% CI: 39.8, 100). **Conclusions:** 3HP-2827 was found to be safe and tolerable, with encouraging anti-tumor activity observed in pts with FGFR2 alterations. Further clinical efficacy will be explored in the expansion stage and phase II stage. Clinical trial information: NCT06378593. Research Sponsor: None.

3115 Poster Session

A first-in-human phase I/II study evaluating CTS3497, an MTA-cooperative PRMT5 inhibitor, in advanced or metastatic *MTAP*-deficient solid tumors. First Author: Dan Liu, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Early Drug Development Centre, Peking University Cancer Hospital & Institute, Beijing, China

Background: Protein arginine methyltransferase 5 (PRMT5) methylates multiple protein substrates with a variety of biological functions known to be dysregulated in cancer. CTS3497 is an orally available, brain-penetrable, MTA (methylthioadenosine) -cooperative PRMT5 inhibitor that preferentially targets the MTA-bound PRMT5 in MTAP (MTA phosphorylase) -deficient tumors and potently inhibits tumor growth in various preclinical models. Here we present clinical data from an ongoing Phase I/II study of CTS3497 in solid tumors (NCT06971523). **Methods:** Eligible pts with homozygous MTAP deletion (by next generation sequencing), or MTAP protein loss (by immunohistochemistry [IHC]) and advanced solid tumors in the dose-escalation stage received 50, 200, 300, 400 mg BID of CTS3497 orally, while pts in the dose-expansion stage were treated with 200, 300 or 400 mg BID until disease progression or intolerable toxicity. Efficacy, safety, PK, PD and biomarker profiles were evaluated. **Results:** As of 22 Jan 2026, 41 patients received ≥1 dose of CTS3497 treatment. No DLT was observed, and MTD was not reached; CTS3497 was well-tolerated. Most common (≥20%) treatment-related adverse events (TRAEs) were anemia (34%), white blood cell count decreased (32%), platelet count decreased (27%) and neutrophil count decreased (22%). The most common Grade ≥3 TRAE (occurring in ≥5% of patients) was platelet count decreased. No central nervous system (CNS) effects were reported. Among 21 centrally-confirmed MTAP-deficient, efficacy-evaluable patients, including 9 gastrointestinal (GI) cancers (ampullary cancer, biliary tract carcinoma, esophageal squamous cell carcinoma, gastric cancer and pancreatic ductal adenocarcinoma), 5 non-small cell lung cancer (NSCLC), 1 urothelial carcinoma and 6 rare cancers, the objective response rate (ORR) was 43%, and the disease control rate (DCR) was 91%. In GI cancers, the ORR and DCR were 56% and 89%. In NSCLC, the ORR and DCR were 60% and 80%. The exposures (Cmax, AUC0-24h) of CTS3497 increased in a linear, dose-proportional manner. The pharmacodynamic (PD) marker, plasma symmetric dimethylarginine (SDMA) level, showed a significant decrease. **Conclusions:** CTS3497 demonstrated a favorable safety profile and promising efficacy in heavily pretreated pts with MTAP-deficient advanced solid tumors, including GI cancers, NSCLC. Clinical trial information: NCT06971523. Research Sponsor: Cytosinlab Therapeutics Co., Ltd.

Efficacy of targeting replication stress in neuroblastoma. First Author: Carla Sofia Sampaio, University of California San Diego, La Jolla, CA

Background: Children with high-risk and relapsed neuroblastoma (NB) need improved therapies, and recurrent cytogenetic abnormalities, such as *MYCN* oncogene amplification, represent candidate therapeutic targets. *MYCN* amplification and increased *MYCN* expression drive deregulated hyper-transcription that leads to development and growth of NB tumors, and *MYCN* amplifications, which can be found both within the linear genome on homogenously staining regions (HSR) and on circular extrachromosomal DNA (ecDNA), are associated with significantly worse survival rates for children with NB. *MYCN* overexpression has been linked to an increase in replication stress (RS), and RS and subsequent genome instability are important drivers of tumor initiation and progression. Flap Endonuclease 1 (FEN1), a non-essential DNA replication enzyme, was identified as a synthetic lethal target in *BRCA1/2*-deficient cancers via induction of RS. Recent success of targeting RS-elevated cancers with replication enzyme inhibitors opens a new avenue to target *MYCN*-amplified NB. **Methods:** Associations of gene expression with patient survival and prognostic features were performed on available neuroblastoma tumor databases using the R2 Genomics Analysis and Visualization Platform. The efficacy of FEN1 inhibition was assessed using live cell imaging and cell viability assays, comparing results in *MYCN*-amplified to -nonamplified NB cells and in NB cells with inducible *MYCN* expression and repression. Mechanisms of cell death and impacts on replication stress in cells treated with FEN1 inhibitors were evaluated by Western blots. **Results:** We have found that *FEN1* expression levels are associated with NB patient outcomes and with features of high-risk disease, including tumor stage and *MYCN* amplification. FEN1 inhibition was effective against NB cells and was significantly more effective in HSR-*MYCN*-amplified NB cells, but not ecDNA-MYCN amplified NB cells, with reduced cell growth and viability. Increased *MYCN* expression also led to increased sensitivity to FEN1 inhibition, and reduced MYCN expression reduced sensitivity. FEN1 inhibition led to the induction of apoptosis but not necroptosis in NB cells and responses to FEN1 inhibition were associated with markers of replication stress, including activation of the ATR-CHK1 and ATM-CHK2 pathways. **Conclusions:** We have discovered that HSR-mediated *MYCN*-amplified NB cells are hypersensitive to FEN1 inhibition, suggesting that FEN1 inhibition may be a promising therapeutic strategy for children with high-risk and relapsed NB. Research Sponsor: None.

***MTAP* deletions and co-mutational landscape from whole genome sequencing in primary CNS tumors.** First Author: Lise Hoej Omland, The Phase I Unit, Department of Oncology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark

Background: Biallelic deletions of the *MTAP* (methylthioadenosine phosphorylase) gene are frequent in solid tumors and confer synthetic lethality to PRMT5 (protein arginine methyltransferase 5) inhibition. Clinical trials are exploring the safety and efficacy of PRMT5 inhibitors (PRMT5i). Targeting additional co-occurring actionable alterations, such as gain-of-function mutations, with kinase inhibitors in combination with *MTAP*-directed synthetic lethality may potentiate therapeutic efficacy. *MTAP* deletions are present in up to 40% of glioblastomas (GBM) and occur sporadically in other primary central nervous system (CNS) tumors. Identification of actionable targets beyond *MTAP* deletions could enable combination strategies in these diagnoses, with otherwise limited therapeutic options. Whole-genome sequencing (WGS) with exon-level copy number alteration (CNA) analysis allows accurate determination of *MTAP* status, assessment of concordance with copy number variations (CNVs) in the neighboring *CDKN2A* and *CDKN2B* genes, and evaluation of the prevalence of co-occurring actionable alterations (including *IDH1, KRAS, PIK3CA, FGFR,* and *NTRK* alterations). **Methods:** A total of 145 consecutive patients with primary WHO grade 4 gliomas or other primary CNS tumors underwent WGS at the time of diagnosis as part of the prospective Neurogenome Study at Copenhagen University Hospital between January 2023 and October 2025. 57 patients (39%) were female, and the median age was 59 years (range, 26–78). *MGMT* promoter methylation was detected in 59 patients (40.4%); 6 tumors were not evaluable for *MGMT* status. 130 cases (GBM, n=118; astrocytoma, *IDH*-mutant, n=12) had reliable *MTAP* copy number analysis, samples with e.g. high fraction of normal tissue where excluded from analysis. **Results:** Among the 130 evaluable cases, 52 (40%) harbored biallelic *MTAP* deletions, 37 (28%) had monoallelic deletions, and 39 (30%) had no *MTAP* deletions. 2 cases (1.5%) had deletion of one *MTAP* allele with partial deletion of the second allele (exon-level deletions). Concordance between *MTAP* CNVs and *CDKN2A/B* CNVs—defined as either biallelic deletion or non-biallelic deletion of both *MTAP* and *CDKN2A/B* genes—was observed in 113 of 130 cases (87%). 31 cases harbored additional potentially actionable alterations. In tumors with biallelic *MTAP* deletions, 9 cases contained co-occurring actionable targets (*FGFR* fusion 1; *KRAS* mutation 1; *NTRK* fusion 1; *PIK3CA* mutation 4; *IDH1* + *PIKCA3* mutations 1; *IDH1* mutation + *PTPRZ1-MET* fusion 1). **Conclusions:** *MTAP* biallelic deletions were frequent at diagnosis in this primary CNS tumor population, whereas partial deletions of the *MTAP* gene (exon deletions) were rare. High concordance with *CDKN2A/B* status on WGS was observed. A subset of cases with biallelic *MTAP* deletions harbored other actionable targets underscoring the potential for combining PRMT5i with other targeted agents. Research Sponsor: None.

3118 Poster Session

Virtual AI-informed immunocyte profiling (VAIP) from H&E as a predictor of multi-cancer prognosis. First Author: Mayukhmala Jana, Department of Biomedical Engineering, Emory University and Georgia Institute of Technology, Atlanta, GA

Background: Improved risk stratification is critically needed across multiple cancers to guide treatment decisions. This includes reducing overtreatment in Ductal Carcinoma in Situ (DCIS), addressing late recurrence risk in estrogen receptor-positive/lymph node-negative (ER+/LN-) breast cancer (BC), and refining prognosis in head & neck squamous cell carcinomas (HNSCC), and high-grade serous ovarian carcinoma (HGSOC). Tumor-infiltrating lymphocytes (TILs) reflect anti-tumor immunity, whereas tumor-associated macrophages (TAMs) polarize toward anti-tumor M1-like (CD68+) or immunosuppressive M2-like (CD163+) phenotypes. Integrating TILs with TAM polarization markers may better capture inflammatory balance and improve outcome prediction. We developed a hematoxylin and eosin (H&E)-only AI method (VAIP) to quantify TILs and virtual CD68/CD163 TAMs to develop multi-cancer based potential prognostic models. **Methods:** TILs were detected on H&E with HoVer-UNet, and virtual CD68 and CD163 macrophages were inferred with VISTA. In cancer regions, we computed cell densities and immune-balance ratios and trained cancer-specific Cox models with compact feature sets (DCIS 6; HGSOC 7; ER+ 4; HNSCC 4). Prognostic stratification used disease-free survival (DFS) for DCIS (N=273), HGSOC (training N=165, independent test N=220), and ER+ BC (training N=144, test N=622), and overall survival (OS) for HNSCC (N=77), reflecting clinical endpoints. Evaluation used cross-validation for cohorts without an external test set (DCIS, HNSCC) and independent training and testing when independent cohort was available (HGSOC, ER+). **Results:** Risk stratification performance across cancer types is in Table 1. The DCIS model used 6 features, largely TIL-macrophage contrast ratios (TIL/M2, TIL/M1). HGSOC used 7 features with a similar ratio-heavy immune-balance signature, plus macrophage-normalized density and polarization metrics (e.g., M1/N, M/N). In contrast, ER+ BC and HNSCC achieved best performance with 4 features dominated by macrophage measures, particularly M2 density and the M1/M2 ratio. Across sites, CD163-related macrophage metrics and immune-balance ratios were consistently informative. **Conclusions:** Integrating H&E-visible TILs with virtual CD68/CD163 TAMs enables fully automated, H&E-only prognostic biomarkers that stratify OS and DFS across multiple cancers, demonstrating consistent prognostic value in DCIS, ER+ BC, HGSOC, and HNSCC. These findings support further study of this histomorphometric risk classifier through broader external and prospective validation. Research Sponsor: None.

Spatial transcriptomic profiling of the tumor microenvironment associated with sunitinib response in metastatic renal cell carcinoma. First Author: Shriya Deshmukh, Comprehensive Cancer Center & James Solove Research Inst., The Ohio State University Medical Center, Columbus, OH

Background: Metastatic clear cell renal cell carcinoma (ccRCC) exhibits heterogeneous clinical outcomes, and limited biomarkers are available to predict response to targeted therapies. This study evaluated cell compartment-specific transcriptional biomarkers predicting clinical response to the tyrosine kinase inhibitor (TKI) sunitinib. **Methods:** In this phase 2 single-arm clinical trial (NCT00715442), 46 patients with metastatic ccRCC received sunitinib pre- and post-cytoreductive nephrectomy. The primary endpoint was time-to-progression (TTP) and secondary endpoints included overall survival (OS) and sunitinib toxicity. To investigate spatial dynamics of therapeutic response to sunitinib, we applied whole-transcriptome digital spatial profiling (DSP) to tumor tissue to identify myeloid, endothelial, CD8+ T-cell and tumor compartment-specific transcriptional differences between responders (complete or partial response) and non-responders (stable or progressive disease). **Results:** For the 46 trial patients, the median duration of follow-up was 9.8 years (95% CI: 9.4 – NA). The median TTP was 8.2 months (95% CI: 6.1-19.3) and OS 36.3 months (95% CI: 19.7-70.5). Sunitinib-related adverse events occurred in 20% of patients, with grade 3 and 4 toxicities including hand-foot syndrome, fatigue, and hematologic abnormalities (thrombocytopenia, neutropenia). DSP analyses demonstrated that sunitinib responders display a tumor microenvironment enriched in pro-inflammatory and immunostimulatory programs. By contrast, non-responders displayed enrichment of immunosuppressive programs with elevated PD-L1 expression in myeloid cells and exhausted CD8+ T-cell signatures. Sunitinib resistance mechanisms involving pro-angiogenic VEGF-dependent and independent pathways were identified in non-responders, revealing potential therapeutic targets in combination with TKIs. Moreover, gene signatures developed based on DSP analysis of sunitinib response accurately predicted sunitinib response in an external patient cohort. **Conclusions:** Our findings underscore the relevance of spatial omics approaches to inform patient stratification and guide precision and combination treatment strategies aimed at mitigating TKI resistance in metastatic ccRCC. Clinical trial information: NCT00715442. Developing harmonized tumor microenvironment subtypes for patient stratification in clinical trials. First Author: Nadezhda Lukashevich, BostonGene Corporation, Waltham, MA

Background: Accurate patient stratification by tumor microenvironment (TME) is critical for optimizing immunotherapy and targeted therapy outcomes. Existing transcriptome-based classification methods often focus on limited TME aspects and tumor types, restricting their clinical utility. Here, we developed a harmonized (H) TME classification by integrating findings from published pan-cancer TME profiling with reported immune evasion mechanisms. **Methods:** We used agglomerative clustering of gene signature scores (ssGSEA) and pathway activities (PROGENy) encompassing immune cells, fibrosis, vascularization, hypoxia, and other signals to acquire 9 transcriptomic HTME subtypes (Table 1) independently on TCGA (n=7,362) and internal (n=5,186) pan-cancer cohorts with high reproducibility (Spearman r=0.94). Next, we validated the subtypes on 29,875 solid cancer samples from open-source transcriptomic datasets by applying the K-Nearest Neighbors classifier. Differential expression analysis followed by Spearman correlation and PCA were used for comparison among classifications. Adjusted Cox models for survival and logistic regressions for response were applied. **Results:** Correlative analysis between existing classifications and HTME subtypes revealed patient stratification along 3 principal biological axes: adaptive immune response vs. tumor cell activity, fibrosis vs. antigen-presenting activity, and proliferation vs. vascularization, with, HTME uniquely covering all three axes. When applied to the selected clinical cohorts, HTME effectively distinguished patients by response (logOR) or progression-free survival (logHR) in a diagnosis- and therapy-specific manner (Table 1; showing values with p≤0.05). **Conclusions:** The proposed HTME patient stratification framework, publicly available and applicable to any RNA-seq sample, constitutes a practical tool for biomarker discovery and trial design across solid tumors. Research Sponsor: None.

Identification of high-grade neuroendocrine carcinoma (HGNEC) biology across tumor types through transcriptomic profiling and validation in lung cancer. First Author: Yatian Yang, Caris Life Sciences, Phoenix, AZ

Background: HGNECs, including small-cell (SC) and large-cell (LCNEC), are aggressive malignancies frequently misclassified due to subtle morphology and inconsistent use of neuroendocrine (NE) immunohistochemistry in routine pathology workflows. It is unclear if tumors with transcriptomic signatures reflecting HGNEC-like biology have inferior outcomes with conventional treatment. Leveraging a large real-world dataset, this study aims to identify transcriptomically defined HGNEC to improve upon morphology-based classification. **Methods:** 49,144 specimens underwent DNA and RNA sequencing at Caris Life Sciences. Using a previously reported framework, we developed a weighted, z-scored based HGNEC activity score (HAS) from 10,137 pathologically defined HG- and LG- NEC specimens and applied it to characterize NSCLC samples (without any pathologist assigned HGNEC diagnosis) further stratified by histology (n=39,007). Overall survival (OS) was obtained from insurance claims data and calculated from specimen biopsy to last contact using Kaplan-Meier and Cox proportional hazards estimates. **Results:** To identify a high-confidence HGNEC-like subpopulation, a HAS threshold (z-score>=3) was applied, classifying 0.2% squamous (sq) and 2.3% non-squamous (nsq) as HGNEC-like; this analysis is focused in nsq. Patient demographics, including age, gender, race, ethnicity, and smoking history, were similar between the HGNEC-like and non-HGNEC-like nsq cohorts. However, biopsies from lymph nodes (26 vs 11%) and brain (9.1 vs 5.6%) were more frequent, and lung (39 vs 56%) less frequent in HGNEC-like tumors (all p-adj<0.05). HGNEC-like tumors were associated with poor OS (HR:1.18, 95% CI:1.07–1.31, p<0.001). HGNEC-like tumors were more frequently PD-L1 negative (64% vs 47%), and were enriched for mutations in *TP53*, *PTEN* and *RB1* (OR: 1.7-14.1), as well as amplifications in *MYC* and *CCNE* (OR: 2.2-3.5), with lower odds of *KRAS* and *EGFR* mutations (OR:0.4-0.5, p-adj<0.05). Consistent with a highly proliferative phenotype, HGNEC-like tumors were enriched for *MKI67* expression (1.4-fold) and higher cell-cycle and replication stress scores (1.5-fold) (all p-adj<0.05) . Gene set enrichment analysis revealed significant activation of neurodevelopmental programs (NES: 2.0-3.0, all p-adj<0.05) and negative enrichment of immune pathways (e.g antigen presentation) (NES: -3.0 to -1.5, all p-adj<0.05). Finally, transcriptomic expression of potentially actionable SCLC-directed targets, including *DLL3* (10-fold), *SEZ6* (3.7-fold), and *SSTR2* (10-fold), were all higher in HGNEC-like tumors (all p-adj<0.05). **Conclusions:** We identify a transcriptomically defined HGNEC-like subset of NSCLC with inferior survival and targetable NEC biology, supporting transcriptomic stratification to inform clinical trial design and selection of SCLC-directed therapies. Research Sponsor: None.

3122 Poster Session

ILF2 as a predictor of cisplatin resistance and clinical outcomes in intrahepatic cholangiocarcinoma. First Author: Kodai Abe, Saint John's Cancer Institute, Santa Monica, CA

Background: Intrahepatic cholangiocarcinoma (iCCA) is a highly aggressive biliary tract cancer with increasing global incidence and limited therapeutic options, partly due to the low prevalence of actionable genomic alterations such as *FGFR2* fusions (~10%) and *IDH1* mutations (~13%). Using single-cell transcriptomic analyses, we identified recurrent amplification at chromosome 1q21.3 as a dominant genomic alteration in iCCA tumor cells. Given our prior evidence linking 1q21.3 amplification to DNA damage–response (DDR) processes and chemotherapy resistance in multiple cancer types, we focused on Interleukin enhancer binding Factor 2 (ILF2), a gene within 1q21.3, and systematically evaluated its multi-omic features and clinical relevance in iCCA using multiple independent clinical datasets. **Methods:** Single-cell RNA sequencing datasets were analyzed using Single-Cell Variational Aneuploidy (SCEVAN) to identify recurrent chromosomal alterations. Bulk RNA and DNA sequencing datasets were assessed for *ILF2* copy number variation (CNV) and mRNA expression. Clinical validation was performed using independent iCCA cohorts from Keio University and SJCI (n=67) and a public dataset (GSE89748; n=49). *In vitro* assays validated the functional role of ILF2 in DDR and cisplatin sensitivity of iCCA cell lines (n=3). **Results:** SCEVAN analysis of GSE125449 (n=8) and GSE138709 (n=5) revealed that 1q21.3 was the only common highest amplified region of iCCA tumor cells (29.7% and 31.1%, respectively). TCGA-CHOL dataset (n=32) demonstrated that *ILF2* CNV amplification occurred in 46.7% of cases and was strongly correlated with increased *ILF2* mRNA expression (r = 0.730, p < 0.001), which was significantly higher in tumor tissue than normal liver tissue in iCCA patients (p < 0.001). In the iCCA validation cohort (n=67) and GSE89748 dataset (n=49), *ILF2* mRNA level upregulation was significantly associated with shorter recurrence-free survival (log-rank test; p < 0.001 and p = 0.047, respectively), and independently predicted recurrence risk (multivariate Cox regression analysis HR = 4.63, 95% CI 1.71 – 12.6, p = 0.003 and HR = 2.73, 95% CI 1.10 – 6.80, p = 0.031, respectively). Consistently, ILF2 protein expression as assessed by multiplex immunofluorescence was significantly lower in FFPE tumor tissues from cisplatin responders than non-responders of iCCA patients (p < 0.001, n=16). Across iCCA cell lines, ILF2 interacted with DDR–related factors to suppress R-loop and γH2AX activities; both events are involved in promoting cisplatin resistance. **Conclusions:** *ILF2* is a frequent novel functional gene strongly associated with adverse clinical outcomes and cisplatin resistance of iCCA. This supports its role as a clinically relevant and theranostic biomarker related to DDR in iCCA patients. Research Sponsor: None.

3123 Poster Session

Target-specific therapy for actionable and approved tumor-agnostic biomarkers: Influence on survival in rare cancers. First Author: Razelle Kurzrock, Medical College of Wisconsin, Milwaukee, WI

Background: Rare cancers - defined as an incidence rate of less than 6 per 100,000 diagnoses per year - collectively account for close to 25% of cancer burden and represent a critical unmet clinical need. The emergence of regulatory approvals for tumor-agnostic therapies based on genomic biomarkers has expanded treatment options for these patients (pts) but clinical sequencing is not yet broadly adopted for rare cancers. Here, we assess the incidence and clinical utility of FDA-approved tumor-agnostic biomarkers in a large real-world rare cancers cohort. **Methods:** The Tempus Lens Platform used to query the de-identified Tempus multimodal database to analyze a cohort of 45,085 real-world pts with 615 rare cancer diagnoses. All pts had DNA (Tempus xT) and/or RNA sequencing (Tempus xR). Pts were screened for FDA-approved tumor-agnostic biomarkers, including high tumor mutational burden (TMB-H, ≥ 10 mut/Mb), high microsatellite instability (MSI-H), NTRK and/or RET fusions, BRAFV600E mutations and HER2 overexpression (IHC-3+). Pts were classified based on their reported biomarker status and treatment start of the approved targeted therapy relative to the FDA-approval date. Real-world overall survival (rwOS) was defined as the time from sample collection to death or loss to follow-up. Hazard ratios (HR) from Cox-proportional hazards models were adjusted for age, sex, race, ethnicity, and stage at p<0.05 (Wald test). **Results:** The median age of pts was 64 years old, 59% were female, 50% of those with documented race were white and 36% had metastatic disease. The most common diagnoses were within the genital system (25%), digestive system (23%), soft tissue (12%), brain (11%) and lung (6.5%). Of the total cohort, 13% (5,881) were positive for at least one tumor-agnostic biomarker. TMB-H was the most prevalent (10.3%), followed by HER2+ (5.5%), BRAFV600E (2.6%), MSI-H (1.9%), NTRK (0.5%) and RET (0.2%) fusions. Of 59% (3,480) of pts with recorded treatments, 33% (1,138) received the approved treatment following the approval date (tumor-agnostic biomarker-positive matched) while 64% (2,227) received other treatments (tumor-agnostic biomarker-positive unmatched). Pts with tumor-agnostic biomarker-positive matched treatments had significantly improved rwOS compared to tumor-agnostic biomarker-positive unmatched pts (HR=0.8, p=0.024) and to tumor-agnostic biomarker-negative individuals (HR=0.68, p<0.001). **Conclusions:** A large percent (13%) of pts with rare cancer diagnoses were found to harbor an actionable biomarker associated with an FDA-approved tumor-agnostic therapy. Pts who received therapies for approved tumor-agnostic biomarkers versus those pts with the biomarker who did not receive the matched treatment demonstrated a significant survival benefit, underscoring the importance of NGS testing to optimize treatment selection for rare cancer pts. Research Sponsor: None.

3124 **Poster Session**

Pan-cancer computational analysis of adaptive immune and vascular changes in primary versus metastatic tumors. First Author: Neil Arya Babu, Renown Health/University of Nevada Reno School of Medicine, Reno, NV

Background: Metastasis drives cancer mortality, yet tumor microenvironment (TME) evolution during systemic spread remains poorly understood. Current paradigms often assume uniform immunosuppression at metastatic sites or seek a universal pro-metastatic signature. We investigated whether a conserved immune signature exists across metastatic sites or if remodeling follows tissue-specific trajectories that could inform precision therapeutic strategies. **Methods:** We performed computational meta-analysis from TCGA using xCell enrichment scores across >20,000 transcriptomic samples from primary tumors and distant metastases in five solid tumor types: Lung (n=1,622), Breast (n=1,543), Kidney (n=1,541), Brain (n=1,243), and Thyroid (n=1,016). Mann-Whitney U testing with Bonferroni correction identified cell populations with differential enrichment (padj<0.05). Cohorts were balanced for age, gender, and race (all p>0.05). **Results:** We identified two convergent metastatic trajectories with opposite directional changes in a four-cell plasticity module: B-cells, class-switched memory B-cells, CD4+ effector memory T-cells, and platelets. The Immune-Vascular Acquisition Trajectory (Breast, Brain, Thyroid) showed metastatic enrichment of all four cell types (Mean Difference [Primary-Metastatic]: -0.62; padj<0.001). The Immune-Vascular Depletion Trajectory (Lung, Kidney) showed significant depletion of all four populations at metastatic sites (Mean Difference [Primary-Metastatic]: +0.74; padj<0.001). Platelet dynamics consistently mirrored adaptive immune trajectories across all cancer types. **Conclusions:** These findings challenge two prevailing assumptions: uniform immunosuppression at metastatic sites and a single universal pro-metastatic immune signature. Instead, metastatic immune remodeling follows organ-specific convergent trajectories driven by adaptive and vascular plasticity. The identification of shared trajectories among biologically distinct cancers suggests that metastatic site microenvironment dictates TME evolution. The de novo acquisition of immune signatures in brain metastases challenges the "immunologically cold metastasis" paradigm, while depletion in naturally immunogenic tumors (Lung, Kidney) indicates TME "cooling" for immune evasion. The invariant coupling of platelet and adaptive immune dynamics highlights vascular remodeling as critical to metastatic niche establishment. These distinct trajectories may explain differential responses to immunotherapy and anti-angiogenic agents across metastatic sites, supporting the need for organ-specific therapeutic strategies. Future studies are needed to investigate whether primary tumors harbor early signatures of this module predictive of metastatic trajectory, enabling stratified surveillance and intervention. Pan-cancer prevalence, molecular landscape, and prognostic impact of *CCNE1* amplification across 76,046 malignancies. First Author: Ricardo Dahmer Tiecher, Memorial Sloan Kettering Cancer Center, New York, NY

Background: *CCNE1* amplification (*CCNE1*amp) is an oncogenic driver that confers synthetic-lethal vulnerability to agents targeting cell cycle and replication stress. While *CCNE1*amp is a poor prognostic marker in some solid tumor types, pan-tumor data are limited. We used the MSK Clinical Sequencing Cohort to characterize its pan-tumor prevalence, molecular landscape, and prognostic impact. **Methods:** We analyzed data from consented patients with solid tumors sequenced by MSK-IMPACT between July 2014 and August 2025. *CCNE1*amp was defined as an amplification or gain per clinical report. Tumor-level prevalence was calculated and reported for histologies with ≥10 CCNE1amp tumors. Co-occurring alterations were evaluated using the first *CCNE1*amp sample per tumor type in each patient, with Fisher's exact test and Benjamini-Hochberg correction. Overall survival was measured from the date of first sequencing to death or last contact. **Results:** Among 76,046 tumors, the prevalence of CCNE1amp was 2.7% (n = 2,036). Our *CCNE1*amp cohort comprised predominantly ovarian (21%, n=435), uterine (15%, n=301), non-small cell lung (11%, n=231), esophagogastric (10%, n=206), and breast cancers (8%, n=168). Prevalence rates were highest in uterine carcinosarcoma (25.6%); ovarian carcinosarcoma (20%); uterine serous carcinoma (16.2%); high-grade serous ovarian carcinoma (15.4%); osteosarcoma (11.9%); gallbladder adenocarcinoma (9.7%); and esophageal adenocarcinoma (9.1%). Prevalence rates in breast cancer were 2.1% and in non-small cell lung cancer 2.6%. Among 67 patients with paired pre- and post-treatment samples of purity ≥30%, *CCNE1*amp was reported in all samples in 42% of patients. The most frequently co-mutated genes were *TP53* (87%), *PIK3CA* (12%), *KRAS* (8%), and *RB1* (7%). Most common amplifications included the 19q neighbors *CEBPA* (31%), *KMT2B* (22%), and *AKT2* (22%); as well as *MYC* (14%); and *ERBB2* (13%). The most significant co-occurrences (q<0.05) were *TP53* mutations (OR 11.5) and *MYC* amplifications (OR 3.5); CCNE1amp was mutually exclusive with *PTEN* (OR 0.37) and *KRAS* mutations (OR 0.55). CCNE1amp samples had a higher median fraction of genome altered (median 0.35 vs. 0.12; p<0.001). *CCNE1*amp was associated with worsened overall survival in a multivariate Cox model stratified by cancer type and adjusted for age, stage and *TP53* status (adjusted HR 1.25; 95% CI 1.17-1.33). Its adverse prognostic impact was more pronounced in *TP53*wt (HR 1.62; 95% CI 1.38-1.91) vs. *TP53*mut tumors (HR 1.19; 95% CI 1.11-1.27; p for interaction <0.001). **Conclusions:** *CCNE1* amplification defines a pan-cancer genomic subset associated with poor prognosis, genomic instability, and few co-occurring actionable alterations, supporting its relevance as a therapeutic target. Discordance between paired samples suggests that a single negative biopsy may not rule out CCNE1amp. Research Sponsor: Memorial Sloan Kettering Cancer Center NCI Support Grant (P30 CA008748).

Early-onset cancer signature (EOCS): Pan-cancer molecular alterations with prognostic significance in early-onset (EOC) and late-onset (LOC) cancer. First Author: Mahesh Iddawela, Peninsula Health & Peninsula Clinical School, Monash University, Frankston, VIC, Australia

Background: Early-onset cancer (EOC) is an emerging global epidemic with biological and molecular features distinct from late-onset cancer (LOC). Improved delineation of genomic pathway aberrations in EOC is essential to inform risk stratification and therapeutic decision-making. However, large-scale, unbiased analyses of biological drivers across tumour types remain limited. To address this gap, we developed a pan-cancer Early-Onset Cancer Signature (EOCS) to advance understanding of the genomic architecture underpinning EOC. **Methods:** The AACR GENIE v16 dataset comprising 241,551 tumour samples was analysed, including 22,408 early-onset cases (≤40 years) and 219,143 late-onset cases (≥41 years) from multiple international repositories. Differentially enriched genomic alterations and pathways between EOC and LOC were identified to define the EOCS. The EOCS was subsequently evaluated across TCGA pan-cancer datasets and validated in independent cohorts, including METABRIC (breast cancer), MSKCC colorectal cancer, and MSKCC prostate cancer datasets. **Results:** Analysis of the AACR GENIE cohort revealed that the most significantly enriched alterations in EOC compared with LOC were CCDC6 (20% vs 10%), SYNE1 (8% vs 6%), BRAF (9% vs 6%), FLI1 (19% vs 0.5%), and EML4 (8% vs 4%). In contrast, alterations significantly enriched in LOC included KRAS (15% vs 5%), TP53 (38% vs 29%), EGFR(15% vs 5%), STK11 (3% vs 1%), and CDKN2A (10% vs 6%). Gene set enrichment analysis of EOCS-associated genes identified DNA recombination, regulation of histone H3K9 trimethylation, and homologous recombination–mediated double-strand break repair as the top three enriched Gene Ontology pathways. The EOCS was altered in 30% (3,736/10,967) of TCGA pan-cancer samples, with the highest prevalence observed in endometrial, skin, carcinosarcoma, and gastric cancers. The most frequently altered genes included SYNE1(12%), CTNNB1 (4%), PPMD1 (3%), BCR (3%), ETV6 (3%), RAD52 (3%), and H3-3A (3%). Across TCGA pan-cancer and tumour-specific cohorts, EOCS alterations were consistently associated with inferior overall survival irrespective of age at diagnosis, including pan-cancer (68 vs 83 months; $p = 9.1 \times 10^{-3}$), breast cancer (142 vs 164 months; $p < 0.04$), colorectal cancer (45 vs 56 months; $p = 1.75 \times 10^{-4}$), and prostate cancer (56 vs 77 months; $p = 2.0 \times 10^{-4}$). **Conclusions:** This pan-cancer Early-Onset Cancer Signature identifies distinct genomic pathways driving tumourigenesis in EOC. The findings provide novel biological insights into disease pathogenesis and highlight potential diagnostic and therapeutic targets, supporting the clinical relevance of EOCS across multiple cancer types. Research Sponsor: None.

Clinical utility of whole transcriptome sequencing for fusion detection in advanced solid tumors: SCRUM-Japan MONSTAR-SCREEN-2. First Author: Takao Fujisawa, Department for the Promotion of Drug and Diagnostic Development, Division of Drug and Diagnostic Development Promotion, Translational Research Support Office, National Cancer Center Hospital East, Kashiwa, Japan

Background: Fusion variants represent established therapeutic targets in precision oncology yet are incompletely captured by conventional targeted DNA panel sequencing. Recent studies have reported that RNA sequencing enables detection of oncogenic fusions and structural variants that escape conventional DNA panel sequencing, particularly complex rearrangements occurring in intergenic regions. Herein, we evaluated the landscape of fusion variant detection by whole transcriptome sequencing (WTS) in advanced solid tumors from the SCRUM-Japan MONSTAR-SCREEN-2, a nationwide molecular profiling project. **Methods:** Patients with advanced solid tumors were enrolled; tumor tissues were profiled using whole exome/transcriptome sequencing (MI CancerSeek, Caris Life Sciences, Phoenix, AZ, USA). For fusion detection comparison, we performed an in silico analysis cross-referencing each fusion detected by WTS against publicly available information from conventional DNA panels including both target gene lists and breakpoint information where available, to evaluate theoretical detectability. **Results:** Among 2,768 patients enrolled as of March 2024, WTS data from baseline tissue samples were available in 2,253 pts across 33 cancer subtypes: the most common subtypes were colorectal adenocarcinoma (n=520), gastric adenocarcinoma (n=306), breast cancer (n = 198), prostate cancer (n=177) and pancreatic cancer (n=156). Pathogenic gene fusions and structural variants were detected by WTS in 122 of the 2,253 patients (5.4%), with a total of 126 pathogenic fusions identified. Among 126 pathogenic fusions, 75 (59.5%) represented variants that would theoretically have escaped detection by targeted panel DNA sequencing methodologies, including druggable kinase fusions (FGFR2, FGFR3, and BRAF). Among 18 patients treated with kinase fusion-targeted therapy with evaluable response data, 1 (5.6%) showed complete response, 3 (16.7%) showed partial response and 11 (61.1%) showed stable disease. WTS identified a MYO5A-BRAF fusion in a patient with melanoma that was undetectable by conventional DNA panel sequencing. Based on this finding, the patient received combination BRAF and MEK inhibitor therapy, achieving stable disease for four months, demonstrating the therapeutic relevance of WTS-guided treatment selection. **Conclusions:** WTS detected fusion variants at a high frequency, highlighting the importance of WTS in precision oncology. Clinical trial information: UMIN000043899. Research Sponsor: SCRUM-Japan Fund.

Pan-cancer *KRAS* atlas of 9,056 Chinese patients: Subtype-specific immuno-genomic profiling to guide G12C, G12D, and pan-*KRAS* strategies. First Author: Panli Peng, Guangdong Second Provincial General Hospital, Guangzhou, China

Background: *KRAS* therapy is shifting from allele-specific inhibitors to pan-*KRAS* strategies. However, pivotal trials are largely Western, and Asian subtype-specific immunogenicity and co-mutation benchmarks remain limited. We present the largest pan-cancer Asian *KRAS* clinogenomic atlas to define these benchmarks and inform treatment selection and trial stratification for the pan-*KRAS* inhibitor era. **Methods:** We analyzed 9,056 Chinese patients with *KRAS* mutations across over 30 tumor types, including pancreatic 27.4%, colorectal 25.1%, NSCLC 20.8%, and biliary tract 10.0%. All underwent ~600 gene next generation sequencing profiling in a CAP/CLIA certified laboratory including all classes of genomic alterations with integrated analysis of clinical variables, treatment history, co-mutations, TMB, MSI, and PD-L1. **Results:** *KRAS* mutations clustered at four hotspot codons: G12 (80%), G13 (9%), Q61 (6%), and A146 (3%). Alleles were dominated by G12D (33.3%), G12V (22.8%), and G12C (11.8%), followed by G13D (7.8%) and G12R (4.6%), together covering 80.3% of patients. Overall, 55% carried non-G12C/D variants. More than one *KRAS* point mutations occurred in 1.8% of the patients and *KRAS* amplification in 2.5%. Co-mutations were common, led by *TP53* (61.7%), *APC* (22.2%), *SMAD4* (17.9%), *CDKN2A* (17.1%), *PIK3CA* (12.5%), *ARID1A* (11.9%), and *STK11* (7.7%). TMB in 98.5% (median 4.0 mut/Mb) with 19.2% TMB-high (≥10 mut/Mb), MSI in 97.4% with 3.5% MSI-H, and PD-L1 in 58.0% with 49.5% positive expression. Subtype patterns were distinct. G12C had the highest TMB-high rate (42.4%) with rare MSI-H (0.8%), supporting targeted inhibition with rational IO combination evaluation. In contrast, G13D showed an Asian-enriched immunogenic phenotype with MSI-H 16.1%, higher than Western benchmarks (7.9%, $P<0.001$), and elevated TMB-high (30.8%). Clinically relevant stratification emerged in NSCLC G12C, with 82.5% male predominance versus about 40% in Western populations ($P<0.0001$) and an age gradient consistent with smoking (67% male <50 years rising to 89% at ≥70 years). Adverse co-mutations were enriched in G12C, including *STK11* (14.4%) and *KEAP1* (9.1%). Multi-*KRAS* mutations were strongly associated with MSI-H (OR 5.48, $P<0.0001$). Conversely, G12R showed an immune-cold profile (TMB-high 3.2%, MSI-H 0.2%), supporting reliance on targeted inhibition rather than IO-based approaches. Nineteen percent of patients were treatment-naive at profiling, most commonly in NSCLC (30%). Versus post-treatment cases, treatment-naive patients were enriched for G12C (15.9% vs 10.4%, $P<0.0001$) and showed higher TMB and PD-L1positives. **Conclusions:** This largest Asian *KRAS* atlas defines actionable benchmarks for precision therapy and provides a molecular rationale for region-specific stratification in global pan-*KRAS* trials. Research Sponsor: None.

Tumor and immune microenvironment remodeling with neoadjuvant trastuzumab deruxtecan in HER2-positive gastric cancer: Exploratory analyses from the phase 2 EPOC2003 study. First Author: Akihito Kawazoe, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: We previously reported the efficacy and safety of neoadjuvant trastuzumab deruxtecan (T-DXd) for HER2-positive gastric and gastroesophageal junction adenocarcinoma (EPOC2003) (Takahari et al., ASCO GI 2024). This exploratory analysis aimed to investigate the associations of baseline molecular features of the tumor, the immune landscape, and their longitudinal changes with the therapeutic efficacy of T-DXd. **Methods:** Tumor samples were collected at baseline, pre-cycle 2, post-cycle 3 (before surgery), and at surgery. We performed bulk/single-cell RNA sequencing (scRNA-seq) and multiplex immunohistochemistry to identify correlates of pathological response. Responders were defined as patients achieving a major pathological response according to the Becker criteria. Blood samples were collected at baseline and post-cycle 3 for circulating tumor DNA (ctDNA) analysis using a clinically validated, tumor-informed, personalized assay (Signatera, Natera, Inc.). **Results:** Baseline HER2 expression did not differ between responders (n= 4) and non-responders (n= 22). In the post-treatment sample analysis, a decreasing trend in proliferation index was observed in responders, whereas this trend was not observed in non-responders, suggesting preferential elimination of proliferative tumor cells by T-DXd. Early on-treatment samples (pre-cycle 2 or post cycle 3) tended to demonstrate upregulation of cytokine signaling, inflammatory, immune response signatures, and CD8+ T cell density in both tumor and stroma regardless of response. Notably, scRNA-seq revealed an expansion of neutrophils, which was more pronounced in responders with a stronger baseline interferon signature. These post-treatment neutrophils displayed upregulated migration, phagocytosis, and degranulation signatures, indicative of enhanced neutrophil mediated anti-tumor activity following T-DXd. ctDNA testing was performed in 18 patients, with a baseline positivity rate of 94.4% (17/18). All responders (3/3) achieved ctDNA clearance after cycle 3, compared with only 35.7% (5/14) of non-responders. **Conclusions:** Neoadjuvant T-DXd therapy induced biological remodeling of the tumor and immune microenvironment. Together with on-treatment ctDNA kinetics, these findings suggest distinct response-associated biological patterns and may help guide future treatment optimization for HER2-positive gastric and gastroesophageal junction adenocarcinoma. Clinical trial information: NCT05034887. Research Sponsor: Daiichi Sankyo.

APOBEC mutational signatures to predict immune checkpoint inhibitor benefit in TMB-low metastatic NSCLC independent of PD-L1 status. First Author: Adar Yaacov, Helmsley Cancer Center, Shaare Zedek Medical Center, Jerusalem, Israel

Background: Most metastatic non-small cell lung cancer (NSCLC) patients are tumor mutational burden (TMB)-low (<10 mut/Mb) and lack validated biomarkers to guide immune checkpoint inhibitor (ICI) use beyond PD-L1 expression. APOBEC mutagenesis, characterized by distinct mutational signatures, has been linked to ICI response in urothelial and head and neck cancers – but primarily in TMB-high tumors. Whether APOBEC activity predicts ICI benefit specifically in TMB-low NSCLC, independent of PD-L1 status, remains unclear. **Methods:** We analyzed a discovery cohort of 857 metastatic TMB-low NSCLC patients treated with ICI from the MSK-CHORD cohort. To distinguish predictive from prognostic effects, we examined 1,328 ICI-untreated TMB-low metastatic NSCLC patients as controls. Findings were validated in an independent cohort of 82 TMB-low, ICI-treated stage IV NSCLC patients using whole exome sequencing (WES). APOBEC positivity was determined using MESiCA, a validated machine-learning algorithm designed to detect mutational signatures from targeted gene panels with low mutation counts (≥4 mutations). Primary endpoints were overall survival (OS) and disease control rate (DCR) in the discovery cohort, and progression-free survival (PFS) and objective response rate (ORR) in the validation cohort. Multivariate Cox regression adjusted for PD-L1 status and age. **Results:** In the discovery cohort, APOBEC-positive (n=52, 6.1%) and APOBEC-negative (n=805) patients were balanced for sex (44% vs 46% male), histology (83% vs 79% adenocarcinoma), and PD-L1 status (40% vs 40%; all $p>0.05$); APOBEC-positive patients were younger (median 64 vs 69 years, p=0.002). The APOBEC-positive group demonstrated significantly improved OS (median 33.7 vs 17.4 months; HR=0.60; 95% CI, 0.42–0.85; p=0.004). The survival benefit was absent in ICI-untreated patients (HR=0.98; 95% CI, 0.76–1.26; p=0.85). Formal interaction testing confirmed that the APOBEC benefit was specific to ICI-treated patients (interaction HR=0.62; p=0.032). APOBEC-positive tumors demonstrated higher DCR at 180 days (21.4% vs 7.6%; OR=3.32; p=0.006). In multivariate analysis adjusting for PD-L1 and age, APOBEC remained independently predictive (HR=0.57; 95% CI, 0.40–0.81; p=0.002). In the validation cohort, APOBEC independently predicted superior PFS (HR=0.23; 95% CI, 0.05–0.94; p=0.020) after adjusting for PD-L1, with numerically higher ORR (55.6% vs 25.4%, p=0.068). **Conclusions:** APOBEC mutational signatures represent a robust, independently validated predictive biomarker for ICI response in TMB-low metastatic NSCLC. Unlike prior studies linking APOBEC predominantly to TMB-high tumors, we demonstrate clinical utility specifically in the TMB-low population, where predictive biomarkers are most needed. This biomarker could expand immunotherapy access for NSCLC patients. Research Sponsor: None.

Dynamics of nectin-4 (N4) expression in urothelial carcinoma (UC): Across disease states. First Author: Hiba Narvel, Division of Hematology and Oncology, Medical College of Wisconsin, Milwaukee, WI

Background: Enfortumab vedotin (EV), which targets N4, has revolutionized advanced UC management. Despite high prevalence of N4 in UC, the temporal stability of N4 is poorly characterized. Conflicting reports describe both decreased and increased expression in metastatic (met) UC compared to primary tumors raising uncertainty as to whether changes reflect antigen loss or quantitative modulation—an issue central to resistance to EV. **Methods:** This single-center retrospective study identified pts with met UC who received treatment (trt) with EV. Demographic, clinicopathologic, trt and survival data (from time of met diagnosis) were recorded. N4 expression was evaluated via immunohistochemistry (IHC) (N4 Clone EPR15163-68) H-Score in available primary (TURBT, cystectomy/nephroureterectomy) and met tissue. H-Score was assessed as N4 positive (+) vs negative (neg,-) (>0 vs 0) and ordinally (neg, low <100, medium 100-200, high >200). Concordance between specimen pairs was assessed using percent agreement, McNemar's test, and weighted Cohen's kappa. Overall survival (OS) was evaluated via Kaplan–Meier methods and exploratory Cox regression. **Results:** We identified 141 pts (median age 70; 71% male; primary: bladder (83%), upper tract (15%), synchronous (2.1%), unknown (0.7%). 93% of primary tumors were N4+ (n=44). In matched TURBT-Cystectomy pairs (n=21), binary status was stable (95% agreement), but ordinal concordance was poor (27% agreement, $\kappa = -0.05$) and significant antigenic dampening was observed: High N4 expression decreased from 90% at TURBT to 29% at cystectomy, with a reciprocal increase in medium-level expression from 10% to 48% ($p<0.001$). 89% of met sites (n=27) were N4+. There were no differences in receipt of prior neoadjuvant chemotherapy (NAC) or 1st line trt between met N4+ and N4- groups. In matched cystectomy and metastases pairs (n=11), binary N4 concordance remained high (82% agreement) with poor ordinal concordance (27% agreement, p=0.12). Neither binary nor ordinal metastatic expression, nor changes in H-score over time, were associated with OS. There were no differences in OS in binary met N4+ vs N4- (p=0.82) nor ordinally classified groups (p=0.43). **Conclusions:** N4 is a stable binary target in UC, maintaining positivity across primary and metastatic sites despite significant quantitative dampening in expression intensity. These findings, although exploratory suggest that tumor evolution and therapeutic resistance may be characterized by dynamic antigen density modulation rather than categorical loss, an interpretation that may help reconcile prior discordant reports of expression changes in metastatic disease. Future studies should evaluate whether the degree of H-score shift (rather than absolute value) correlates with the durability of response to EV as well as the impact of neoadjuvant and subsequent sequential treatments on N4 expression intensity. Implementing clinical-scale multiscale spatial transcriptomics: Tumor architecture profiling in SCRUM-Japan MONSTAR-SCREEN-3. First Author: Mitsuho Imai, Translational Research Supporting Office, National Cancer Center Hospital East, Kashiwa, Japan

Background: Spatial interactions between tumor cells and the tumor microenvironment (TME) influence disease progression, yet current diagnostic profiling lacks spatial resolution. A clinically implementable framework enabling cross-cancer spatial characterization using pretreatment clinical specimens is needed. SCRUM-Japan MONSTAR-SCREEN-3 (MONSTAR3) is an ongoing prospective clinical screening platform enrolling over 3,200 patients with solid tumors, integrating clinical annotation with multi-omic. We report an intermediate analysis validating the feasibility of extracting reproducible spatial phenotypes from pretreatment specimens at clinical scale. **Methods:** Spatial transcriptomics (Xenium 5K) was performed on 331 pretreatment FFPE tumor specimens from 309 patients representing ≥15 solid cancer types enrolled in MONSTAR3. Specimens obtained at diagnosis or prior to systemic therapy included unresectable advanced and curative-intent settings. Analyses examined spatial organization of tumor–immune interactions at the TME level, cancer cell functional states, neighborhoods, and tertiary lymphoid structures. Spatial features were systematically compared across cancer types and disease settings without treatment outcomes. **Results:** We generated a spatial atlas comprising approximately 20 million cells with high-confidence annotation across over 15 cancer types, representing one of the largest clinically annotated pan-cancer spatial transcriptomic resources to date. The atlas captures tumor-microenvironment organization, cancer-intrinsic functional heterogeneity, conserved cellular niches, and specialized immune structures including tertiary lymphoid structures with defined maturation states. Spatial tumor architecture varies substantially across cancer types despite similar cellular composition, underscoring value of spatially-resolved profiling beyond conventional cell-type quantification. Analysis across disease stages revealed that advanced tumors exhibit higher spatial compartmentalization of cancer functional states, with immunogenic and proliferative cancer populations showing consistent spatial separation across cancer types. Pan-cancer niche analysis identified conserved cellular neighborhoods, a subset of which showed stage-specific enrichment or prognostic associations. We also performed detailed spatial characterization of tertiary lymphoid structures, which demonstrated association with immunotherapy response in an independent cohort. **Conclusions:** We present a large-scale pan-cancer spatial atlas integrated within a nationwide precision oncology framework. This resource enables systematic investigation of spatial tumor biology and nominates spatially-defined features as candidate biomarkers for patient stratification and therapeutic response studies. Research Sponsor: None.

AACR GENIE analysis of 211,526 patients to evaluate hormone receptor alterations across solid tumors: Rationale for tissue-agnostic basket trials. First Author: Niamh Coleman, Trinity St James's Cancer Institute, Dublin, Ireland

Background: Steroid Hormone receptors (HR) that include estrogen receptor (ER), progesterone receptor (PR), and androgen receptor (AR) were oncology's first predictive biomarkers, yet HR-directed therapies remain largely confined to breast, prostate, and endometrial cancers. Emerging data suggest broader HR relevance across tumor types. The development of oral SERDs (selective ER degraders) and next-generation AR degraders/antagonists creates new opportunities to target HR alterations across tumor types. We performed pan-cancer genomic profiling to define the landscape of ESR1/AR alterations and resistance co-alterations, providing rationale for biomarker-enriched basket trial designs. **Methods:** We analyzed the AACR Project GENIE v18 public dataset, comprising 250,018 tumor samples from 211,526 patients across multiple solid tumor types. Genomic alterations in ESR1 and AR were assessed, including mutations, copy-number alterations, and structural variants. Co-alterations with selected genes involved in resistance and cell-cycle regulation (PIK3CA, PTEN, AKT1, TP53, RB1, CDKN2A) were evaluated using pairwise co-occurrence analyses. **Results:** Across 250,018 solid tumor samples, ESR1 alterations were identified in 2.0% of cases, with highest prevalence in breast (8.4%) and endometrial cancers (4.6%), and lower frequencies in uterine sarcoma (2.7%) and melanoma (3.6%). Most ESR1 alterations were missense mutations localized to the ligand-binding domain, with recurrent hotspots at codons Y537 and D538. AR alterations were present in 2.4% of samples overall, most frequently in prostate cancer (7.6%), and were also detected in endometrial cancer (5.5%), lung cancer (~5%), and melanoma (4.9%). AR alterations consisted predominantly of copy-number amplifications, with additional ligand-binding domain mutations observed. Co-alteration analyses demonstrated frequent co-occurrence of ESR1 with PIK3CA, PTEN, and AKT1, and AR with TP53, RB1, and CDKN2A, whereas ESR1 and KRAS alterations did not significantly co-occur. **Conclusions:** Recurrent ESR1 and AR alterations occur in 2-5% of diverse solid tumors beyond breast, prostate, and endometrial cancers, with co-enrichment of PI3K-AKT and cell-cycle pathway alterations mirroring resistance patterns in canonical HR-driven malignancies. These findings support systematic evaluation of selective ER and AR degraders in biomarker-selected basket trials, expanding precision oncology beyond anatomically-defined indications. Research Sponsor: None.

Impact of first-line comprehensive genomic profiling on survival outcomes for patients with advanced solid tumors who received molecularly-matched therapies: 3-year follow-up of the prospective FIRST-Dx study. First Author: Sadakatsu Ikeda, Department of Precision Cancer Medicine, Institute of Science Tokyo, Tokyo, Japan

Background: Comprehensive genomic profiling (CGP) by next-generation sequencing has been reimbursed in Japan since 2019. However, only 8.2% of patients (pts) had received molecularly-matched treatments. One major reason for this limited drug accessibility is that CGP is covered only after progression with standard of care (SoC). We previously reported that first-line CGP using FoundationOne CDx in advanced solid tumors (FIRST-Dx study) could identify molecular-based recommended therapy (MBRT) for 61% of pts (105/172), and 22.7% (39/172) could be treated by MBRT (JAMA Netw Open 2023, Cancer Sci 2025). To evaluate the impact of the first-line CGP test on survival outcomes, a 3-year follow-up analysis was conducted. **Methods:** The FIRST-Dx study was a multi-institutional prospective study in Japan. A total of 172 chemotherapy-naïve adult pts with advanced solid tumors (GI, Lung, Breast, GYN, Melanoma) and ECOG performance status of 0-1 were registered. This follow-up study was planned for 3 years after the final patient enrollment. The primary endpoint was overall survival (OS). Secondary endpoints were the proportion of pts receiving MBRT, overall response rate, progression-free survival (PFS), and PFS ratio (PFS on MBRT/PFS on prior therapy). **Results:** Median follow-up period was 25.0 months (0.5–45.2). Forty-six pts (26.7%) received MBRT. The number of pts treated with MBRT was 21 in the 1st-line, 22 in the 2nd-line, 6 in the 3rd-line, and 6 in the 4th-line or later setting. Median OS was significantly longer in pts treated with MBRT (not reached) than in those who did not receive MBRT (26.2 months, HR 0.62 [95% CI: 0.39–0.99], log-rank p=0.047). PFS and response rates were shown in Table. Among pts who received 2nd-line MBRT (N=15), the median PFS ratio (PFS on MBRT in 2nd-line/PFS on 1st-line therapy), was 1.2 (range: 0.4–14.6), and 7 pts (47%) achieved a PFS ratio of >1.3, indicating a clinically meaningful benefit of the first-line CGP based MBRT. In an exploratory analysis, propensity score matching (age, sex, cancer type) was performed between pts registered in this study and concurrent real-world pts who did not undergo the first-line CGP, resulting in 67 pts per group. Median OS was significantly longer in the FIRST-Dx group than in the real-world group (23.5 months vs 13.4 months, HR 0.61 [95% CI: 0.40–0.94], log-rank p=0.02). **Conclusions:** MBRT identified by CGP in the first-line setting improved access to targeted therapies and was associated with superior survival outcomes than SoC in advanced solid tumors. Our data suggest that CGP in Japan should be available prior to SoC initiation. Clinical trial information: jRCT1050220041. Research Sponsor: Chugai Pharmaceutical Co., Ltd.

Median progression-free survival and response rate.

	MBRT	SoC	p-value
Median PFS (months)			
1st-line	13.7	11.3	0.04
2nd-line	11.0	5.6	<0.01
Response Rate (%)			
1st-line	52.4	37.8	0.24
2nd-line	45.5	13.2	<0.01

Carcinomas of unknown primary treated with molecularly guided therapies and immune checkpoint inhibitors: A subset from the I-PREDICT N-of-1 Precision Oncology study. First Author: Eric Roth, UC San Diego Moores Cancer Center, La Jolla, CA

Background: Carcinoma of unknown primary (CUP) is a heterogenous group of aggressive malignancies lacking a detectable primary site and collectively comprises 3–5% of cancer diagnoses. Current treatments rely upon empiric chemotherapeutic regimens with high toxicity, limited efficacy, and historic median overall survival times of 3-11 months. There is emerging evidence to support a precision medicine approach using molecularly guided therapies and tumor-agnostic biomarkers. **Methods:** We performed a subset analysis of patients previously enrolled in the I-PREDICT (NCT02534675) study who had a CUP that was treated with a combination of targeted therapies and biomarker-driven immune checkpoint inhibitors (ICI), based upon comprehensive genomic profiling and recommendations by a Molecular Tumor Board. **Results:** Among the 210 evaluable patients, 10 (4.8%) had a CUP from which 9 were molecularly matched to one or more targeted therapies and an ICI based on biomarkers for both types of agents. Baseline characteristics include median age of 67 years (range: 59 – 82), with the majority of patients being male (5/9, 56%), non-Hispanic white (7/9, 78%) and treatment naïve (8/9, 89%). Histological subtypes of CUP included poorly differentiated or unspecified (5/9), adenocarcinoma (3/9) and squamous cell carcinoma (1/9). Administered targeted therapies included bevacizumab (4/9), trametinib (4/9), palbociclib (1/9), crizotinib (1/9), everolimus (1/9), and lenvatinib (1/9), while ICI included nivolumab (6/9), pembrolizumab (2/9) and atezolizumab (1/9). ICI were matched based on positive PD-L1 immunohistochemistry (IHC) (6/9), TMB ≥10 mutations/megabase (4/9), SWI/SNF chromatin remodeling gene alterations (3/9), PD-L1 amplification (1/9), mismatch repair gene alterations (1/9) and microsatellite instability-high (1/9). Most patients were matched to >1 ICI biomarker (5/9). Most patients received treatment doublets (6/9, 67%) while the remaining received triplet regimens (3/9, 33%). The best overall response rate was 44% based on RECIST 1.1. This included partial response (4/9), stable disease (3/9), progressive disease (1/9) and not restaged (1/9). Median progression free survival (PFS) was 10.4 months (95% confidence interval [CI] 4.2 - not estimable [NE]) and median overall survival was 16.9 months (95% CI 6.9 - NE). One patient in particular achieved 36-months of PFS on trametinib + nivolumab as matched to NF1 R440* and PD-L1 IHC 5%. Grade ≥3 treatment related serious adverse events occurred in only one patient. **Conclusions:** As compared to historic chemotherapy treated cohorts, these results support the safety and efficacy of administering molecularly guided combination therapies including a targeted agent plus an ICI in CUP patients. Larger prospective trials of biomarker-matched N-of-1 combinations in CUP are warranted. Clinical trial information: NCT02534675. Research Sponsor: None.

Association of treatment-induced decrease of tumor chromosome Y and prognosis. First Author: Dan Theodorescu, University of Arizona Comprehensive Cancer Center, Tucson, AZ

Background: Loss of chromosome Y (LOY) in cancer has been linked to increased mortality. Since tumors that are not completely eradicated often harbor additional molecular changes which may alter biological behavior, here we sought to examine if therapy has any impact on tumor chromosome Y content and if so, the relevance this has on patient outcome. Changes in chromosome Y content with therapy would impact clinical decision making in patients with persistent or recurrent tumors since tumors with LOY have also been shown to be more responsive to specific therapies. **Methods:** Male patients with >=2 sequential tumor samples profiled at Caris Life Sciences (Phoenix, AZ) who received systemic therapy between collections were included. RNASeq was performed using NovaSeq platform. Chromosome Y score (YChr score) was calculated using ssGSEA (log-rank normalization) based on a previously published 9-gene signature (*Nature* 2025). Change in YChr score between pre and post treatment paired samples (ΔYChr) was computed per patient. A decrease in YChr score in post sample compared to pre sample was defined as ΔYChr ≥0.029 (cohort mean) and called progressive LOY (pLOY) while the remainder were called no-pLOY. Real-world clinical data were obtained from insurance claims. Overall survival (OS) was defined from first sample collection to last contact. Hazard ratios (HRs) were estimated using Cox proportional hazards models, with log-rank p values reported. **Results:** Among 1,343 patients with paired samples, pLOY was associated with shorter OS compared with no-pLOY (median OS [mOS]: 33.2 vs. 36.0 months; HR 1.168, 95% CI 1.028–1.326; p=0.0167). Tumor-specific analyses demonstrated significantly worse OS in pLOY versus no-pLOY for colorectal cancer (CRC; N=124 vs. 157; mOS 38.9 vs. 50.6 months; HR 1.535, p=0.0038), bladder cancer (N=26 vs. 41; mOS 25.7 vs. 37.7 months; HR 1.992, p=0.0204), NSCLC (N=100 vs. 134; mOS 27.6 vs. 32.7 months; HR 1.379, p=0.0379), and gastric cancer (N=13 vs. 16; mOS 17.6 vs. 28.5 months; HR 2.603, p=0.0223), with a trend observed in melanoma (N=17 vs. 27; mOS: 31.4m vs. inf, HR: 2.231 [0.922-5.4], p=0.075). No association was observed in other tumor types. Treatment distributions for mentioned cancer types did not differ between pLOY and no-pLOY groups (p>0.05). Among CRC patients with primary-to-metastatic paired samples (57%), pLOY remained significantly associated with worse OS (mOS 39.5 vs. 56.3 months; HR 1.647; p=0.0112). pLOY was not associated with specific therapies or combinations across the full cohort. **Conclusions:** In a large real-world clinico-genomic cohort, longitudinal decrease in Chromosome Y score is independently associated with poor prognosis across multiple cancer types supporting further investigation into the biological and clinical relevance of Y chromosome loss and providing insights on novel treatment selection strategies. Research Sponsor: None.

Detection of mutational signatures in advanced cancer patients using clinical-grade specimens. First Author: Samantha Rueckeis, Durham Veterans Affairs Health Care System, Durham, NC

Background: The underlying extrinsic and/or intrinsic mutational processes underlying tumor development lead to genome-wide "passenger" alterations that can be identified as mutational signatures. Mutational signatures are known to be both prognostic and predictive in certain clinical contexts. Whole genome sequencing (WGS) based approaches are optimal for detection of mutational signatures but to date studies using formalin fixed paraffin embedded (FFPE) clinical grade specimens are limited. **Methods:** Archival DNA specimens from tumors of United States Veterans that underwent clinical sequencing in the VA National Precision Oncology Program were subjected to 30X WGS. Somatic alterations were identified by a tumor-only variant calling method employing filtering of variants found in the dataset at >10% frequency and putative germline variants found in multiple databases and germline WGS from the Million Veteran Program (MVP). Mutational signatures were identified using deconstructSigs. **Results:** WGS was performed on 134 tumor samples with matched germline WGS from MVP; variants were called using the tumor-only variant calling pipeline in addition to tumor-normal calling. Tumor-only WGS derived tumor mutational burden (TMB) was highly correlated with TMB from clinical targeted sequencing (White, R2=0.48; Black, R2=0.63; Other, R2=0.85) and with TMB from tumor-normal variant calling (White, R2=0.96; Black, R2=0.63; Other, R2=0.85). We used our tumor-only variant calling pipeline on WGS from 397 tumors. The median (+SD) number of mutations per tumor varied per tumor type, with the lowest number in head and neck squamous cell carcinomas (12445+4186 mutations) and highest in melanoma (119089+259854 mutations). Overall, 66 single base substitution (SBS) mutational signatures were identified. The SBS1 clock signature was found in 339 of 397 tumors. The SBS4 smoking mutational signature was found in 100% of small cell lung cancers (n=5), 76% of lung squamous cell cancers (n=38), 50% of lung adenocarcinomas (n=50), 36% of cancers of unknown primary (n=14), 29% of bladder cancers (n=7), and 14% of HNSC (n=36), but was not found in any other cancer type. The SBS7a UV mutational signature was found in 80% of melanomas (n=10) and 7% of cancers of unknown primary, but not in any other cancer type. Finally, the SBS6 and SBS15 mismatch repair mutational signatures were found in 10 and 12 of 16 MSI-high tumors, respectively. **Conclusions:** We have established a pipeline for evaluation of mutational signatures from tumor-only WGS of clinical grade FFPE tumors. Preliminary analysis shows identification of expected mutational signatures. Work is ongoing to determine whether ancestry matched panel of normals improves signature identification and to determine the prognostic and/or predictive ability of mutational signatures in a variety of clinical contexts which could greatly expand the clinical utility of WGS in advanced cancers. Validation of SNHG11 as a prognostic and predictive biomarker for anti-EGFR benefit in colorectal cancer using real-world data. First Author: Michela Bartolini, Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy

Background: Long non-coding RNAs (lncRNAs) regulate colorectal cancer (CRC) initiation, progression, and therapeutic response through interactions with oncogenic and microenvironmental pathways. *SNHG11* has been implicated in CRC through epigenetic and c-Myc–driven transcriptional programs. In CALGB/SWOG 80405, higher tumor *SNHG11* expression correlated with improved outcomes, particularly anti-EGFR therapy (Bartolini 2025, ASCO 43; 16_suppl). We comprehensively evaluated molecular correlates with *SNHG11* and validated the prognostic and predictive value in an independent real-world CRC cohort. **Methods:** In total, 15,456 CRC underwent DNA (592-gene or whole exome) and RNA (whole transcriptome) sequencing at Caris Life Sciences. Tumors were stratified by *SNHG11* expression quartiles, comparing low (Q1) vs high (Q4). CMS classification was assessed using RNAseq. Associations were assessed using X^2/Fisher's exact with p-values adjusted for multiple comparisons (q<0.05). Clinical outcome was obtained from insurance claims. Overall survival (OS) was calculated from tissue collection to last contact and time-on-treatment (ToT) from treatment start to end. Cox proportional hazards model generated hazard ratio (HR) and log-rank p-values. **Results:** *SNHG11* Q1 tumors were associated with higher right-sided prevalence (28% vs 18%, p<0.001), lower left-sided prevalence (50% vs 62%, p<0.001), and older age than Q4 (64 vs 62, p<0.001). Consistent with the findings in CALGB/SWOG 80405, Q4 were associated with CMS2 (53% vs 19%, p<0.001) while Q1 with CMS4 (49% vs 21%, p<0.001). Q1 tumors showed increased MSI-H/dMMR, TMB-H and PD-L1 expression (10% vs 3%, 15% vs 5% and 5% vs 2%, respectively, all p<0.001). *TP53* and *APC* mutations were enriched in Q4 vs Q1 (84% vs 69% and 85% vs 72%, p<0.001) whereas *KRAS* (49% vs 41%), *BRAF* (13% vs 7%), *ARID1A* (12% vs 8%), *RNF43* (6% vs 2%) and *CTNNB1* (3% vs 2%) mutations were higher in Q1 vs Q4 (p<0.001). Q4 was associated with longer OS vs Q1 (mOS 30.8 vs 27.8 months; HR 0.93; 95% CI 0.89–0.97, p<0.001). After adjusting for MSI status, tumor sidedness, age, race, and anti-EGFR therapy, Q4 remained a significant independent predictor of improved OS compared to Q1 (adjusted HR=0.93; 95% CI: 0.89-0.96; p<0.001). Q4 was significantly associated with longer ToT in patients receiving anti-EGFR therapy vs Q1 (7.4 vs 5.8 months, HR 0.86; 95% CI 0.79–0.93, p<0.001) with no association observed with bevacizumab ToT. **Conclusions:** In this large independent real-world cohort, we provided additional molecular insight into a key lncRNA *SNHG11* in CRC. Consistent with previous findings in a large randomized controlled trial, we confirm that elevated *SNHG11* expression was associated with CMS2, left-sided tumors, longer OS and longer TOT of anti-EGFR therapy, supporting *SNHG11* as a promising prognostic biomarker and a candidate predictive biomarker for anti-EGFR benefit in CRC. Research Sponsor: None.

Sensitivity of portal vein ctDNA versus peripheral blood in predicting post-operative liver metastasis adjuvant therapy in colorectal cancer. First Author: Jin Gu, Peking University Cancer Hospital; Peking University Shougang Hospital, Beijing, China

Background: The detection of minimal residual disease (MRD) in colorectal cancer (CRC) is crucial for predicting postoperative recurrence, particularly liver metastasis. While peripheral blood (PB) liquid biopsy is widely used, portal vein blood (PVB) may offer higher sensitivity due to direct drainage of the hepatic circulation. **Methods:** We prospectively enrolled 297 CRC patients undergoing curative surgery. Intraoperative portal vein blood (PVB) and matched preoperative peripheral blood (PB) samples were collected simultaneously. Cell-free DNA was sequenced using a targeted 689-gene panel (1.5 Mb). Variants were filtered to retain only those with increased allele frequency (AF) in PVB relative to PB or exclusive detection in PVB (AF ≥1%), followed by stringent germline and noise removal. Binary mutation matrices were constructed for both blood sources. Machine learning (random forest, SVM, logistic regression, gradient boosting) was used to identify predictive gene signatures separately for PVB and PB. Model performance was compared using five-fold cross-validation. **Results:** PVB-derived ctDNA detected a significantly higher number of tumor-specific mutations compared to PB (mean 3.2 vs. 1.4 mutations per patient, p<0.001). PVB contained significantly higher ctDNA concentration (median 8.4 ng/mL vs 2.1 ng/mL in PB, p<0.001). A 20-gene panel selected from PVB data demonstrated superior predictive accuracy for liver metastasis compared to PB-derived markers. When validated in the same cohort, the PVB panel achieved an AUC of 0.849 (95% CI: 0.802–0.891) versus 0.714 (95% CI: 0.653–0.771) for PB-based prediction (p=0.003). Sensitivity for predicting liver metastasis was 70.0% for PVB versus 48.5% for PB. The PVB panel identified 26.6% of mutation carriers as high-risk, with 100% specificity (no recurrence in mutation-negative patients). In contrast, the PB model failed to achieve comparable risk stratification, with lower positive predictive value and higher false-negative rates. **Conclusions:** Portal vein blood ctDNA analysis is significantly more sensitive and accurate than peripheral blood in predicting postoperative liver metastasis in CRC. PVB-based liquid biopsy provides superior risk stratification, which could better inform adjuvant therapy decisions—identifying high-risk patients for intensified surveillance or treatment, while reducing overtreatment in low-risk patients. These findings support the clinical integration of PVB sampling for MRD detection in CRC surgical practice. Research Sponsor: None.

Spatial mapping of human colorectal cancer cell states to identify co-targeting opportunities and determinants of drug response. First Author: Gertjan Rasschaert, Laboratory for Digestive Oncology, KU Leuven, Leuven, Belgium

Background: Colorectal cancer (CRC) progression relies on multiple mechanistically distinct proliferative and survival programs differing in lineage dependence, plasticity, and environmental sensitivity. LGR5-driven proliferation represents a stem-like program, whereas non-LGR5 modes—including progenitor, KRAS/MAPK, AP-1, and YAP-driven proliferation—reflect inflammatory and adaptive states that may confer therapeutic resistance. Single-cell studies revealed these programs, but technical barriers have restricted their quantitative and spatial analysis in human tumors, limiting translation to drug development and patient stratification. **Methods:** We integrated single-cell RNA sequencing (81 CRC patients) with spatial transcriptomics (Xenium; 16 matched primary CRC samples) to quantify epithelial cell states and tissue organization. Analyses focused on proliferative programs defined by LGR5, CDX2, ANXA1, and MKI67, stratified by KRAS genotype and intratumoral location, with extended spatial annotation of immune and stromal niches. **Results:** CRC tumors showed high compositional heterogeneity across subgroups (mean normalized Shannon entropy >0.6). On average, 36% of tumor epithelial cells were proliferative; only 50% expressed LGR5, with substantial inter-patient variability and genotype dependence. 14% of proliferating cells expressed ANXA1 alone, corresponding to inflammatory, YAP-high states with potential cytotoxic implications. LGR5-driven proliferation was enriched in KRAS-mutant tumors, contrasting with mouse models suggesting KRAS-mediated suppression and potentially indicating reduced sensitivity to KRAS inhibition. EGFR−LGR5 double-positive cells were abundant, identifying additional targetable niches. Spatial analyses revealed regions with high TGFβ signaling and co-localization with $SPP1^{+}$ macrophages consistent with TGFβ-driven immunosuppressive niches described in complementary studies. These niches associate with reduced PD-1/PD-L1 blockade response, coincide with states responsive to combined TGFβ and PD-1 inhibition, and are not captured by genotype alone. **Conclusions:** Spatial transcriptomics provides quantitative, systems-level resolution of tissue architecture, revealing opportunities for rational co-targeting to disrupt tumor homeostasis and enhance immunotherapy efficacy. Ongoing analyses of neoadjuvant-treated tumors and paired primary–metastatic samples will extend this framework to capture therapy-induced and naturally evolving tumor states. Research Sponsor: None.

Phase 1/2 trial of ATR inhibitor berzosertib plus immune checkpoint inhibitor avelumab in patients with advanced cancers with DNA damage response (DDR) gene alterations: Tumor microenvironment–mediated pathways of resistance from correlative data. First Author: Patrick Glen Pilié, Department of Genitourinary Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Herein we present novel correlative data from baseline and on-treatment tumor and blood sampling with associated therapeutic outcomes from a phase 1/2 trial of ATRi (berzosertib) plus ICI (avelumab) in patients (pts) with advanced cancers with pathogenic mutations in select DDR genes. **Methods:** 17 pts enrolled on trial, and they received berzosertib (day 1, 8, 15, 22) plus avelumab (day 1 and 15, q28 days). Paired tumor biopsies were collected at baseline and on Day 12 of treatment, with spatial gene expression profiling (Visium) performed on the tumor tissues. Spot-level bioinformatics and manual annotations were performed to identify regions enriched for tumor cells and key TME components. Blood was collected at baseline and longitudinally for high-dimensional CyTOF profiling for immune cell populations and Luminex for circulating cytokines. **Results:** The ATRi + ICI combination was safe and well tolerated as previously reported, with ORR of 12.5% in this heavily pre-treated study population, with 2 durable RECISTv1.1 partial responses observed in advanced HPV+ vaginal cancer pt with pathogenic somatic *RAD51* mutation lasting 23 months and an advanced colorectal cancer with *MSH2* mutation lasting >24 months. In liquid sampling (N=16 pts), CyTOF analysis revealed a common baseline monocyte "stress-brake" state marked by elevated MRE11 and impaired antigen presentation. Treatment resulted in relief of innate DNA stress and induction of a myeloid-to-lymphoid immune shift, with subsequent expansion of adaptive T-cell effectors (EM1 CD4 T cells), with the durable responses characterized by an early proliferative CD8 T-cell burst (D12–D28) followed by sustained lymphoid dominance. Luminex assay revealed substantial cytokine remodeling at D12–D28 relative to baseline, with multiple analytes exceeding the predefined effect-size threshold ($|\log2FC| \geq 0.58$; ~1.5-fold), suggesting an acute inflammatory response and myeloid infiltration. Spatial profiling in non-responders showed high baseline levels of cancer associated fibroblasts (CAFs) and intra-tumoral CNV heterogeneity, with treatment resulting in upregulation of immunosuppressive, pro-survival pathways (SPP1, MIF, MYC, and Annexin). In contrast, the available on-treatment pt tissue from the vaginal cancer responding tumor displayed higher lymphoid infiltrate and lower immune suppression genes. **Conclusions:** Despite universal acute immune activation in circulation following ATRi + ICI, resistant tumors displayed high CNV heterogeneity, CAFs, and increased immunosuppressive pathways, in contrast to responder tissue. Co-clinical studies will further elucidate targetable mechanisms of resistance and guide further DDRi and ICI combinations. Clinical trial information: NCT04266912. Research Sponsor: None.

Genomic and transcriptomic correlates of HER3 expression in prostate cancer. First Author: Syed Saqib Balkhi, Stephenson Cancer Center, University of Oklahoma Health Sciences, Oklahoma City, OK

Background: HER3 (*ERBB3*) is a key receptor in prostate cancer (PC) that signals via HER3 heterodimerization to promote PI3K-AKT-mediated survival and adaptive resistance in castration-sensitive (CSPC) and castration-resistant prostate cancer (CRPC). Despite its biological relevance, the clinical and genomic significance of HER3 RNA expression remains poorly defined. We therefore performed a comprehensive multi-omic analysis to evaluate the prognostic relevance of HER3 RNA in PC. **Methods:** DNA (592-gene or whole exome) and RNA (whole transcriptome) sequencing were performed on prostate tumor samples (n=19,238) submitted to Caris Life Sciences. HER3 expression was quantified as transcripts per million (TPM) and stratified into high (HER3-H) and low (HER3-L) groups defined by the top and bottom quartiles, respectively. CRPC was defined as $\geq$3 months of androgen deprivation therapy before tissue collection. Real-world overall survival (rwOS) was obtained from insurance claims data and calculated from biopsy to last contact. Tumor microenvironment (TME) cell fractions were estimated by RNA deconvolution using quanTIseq. Group comparisons were conducted using Mann–Whitney U and chi-square tests as appropriate. Survival outcomes were evaluated using Cox proportional hazards models and log-rank testing, with false discovery rate correction for multiple comparisons. **Results:** Across genitourinary malignancies, PC demonstrated highest median HER3 RNA expression (107.04 TPM). Within PC, HER3 expression varied by tumor site and race, with higher median levels in primary tumors compared to metastatic sites (116.5 vs 86.22 T PM, $p<0.0001$), and in tumors from Black patients compared with White patients (115.3 TPM v 103.3 TPM, $p<0.0001$). Prognostic associations differed by tumor source and castrate status: HER3-H expression was associated with improved rwOS in metastatic tumors (32.0 vs. 23.3 months, HR 0.72, $p < 0.00001$), and in CRPC (29.3 vs. 21.3 months; HR 0.84; $p < 0.001$), but not in primary tumors or CSPC. Immune profiling revealed that HER3-high tumors exhibited significantly reduced inferred infiltration of Tregs, neutrophils, macrophages, and NK cells ($q < 0.05$), while PD-L1 positivity and TMB-high status were not significantly associated with HER3 expression. Genomic analysis revealed enrichment of *FOXA1* and *SPOP* alterations ($q<0.05$) in HER3-H tumors, whereas HER3-L tumors were enriched for *TP53*, *RB1*, *AR*, *CDK12*, and *APC* ($q<0.05$). On multivariable analysis, HER3-H status remained independently associated with improved rwOS in CRPC. **Conclusions:** HER3 RNA expression defines biologically and clinically distinct subsets of PC, with HER3-high tumors exhibiting luminal, androgen receptor–dependent biology, an immune-cold phenotype, and improved survival in metastatic disease and CRPC, supporting HER3 as a tumor-intrinsic therapeutic target and rationale for HER3-directed therapy. Research Sponsor: None.

Can GLP-1 receptor agonists mitigate cancer progression? A propensity-matched analysis across seven solid tumors. First Author: Mark David Orland, Department of Hematology and Medical Oncology, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH

Background: GLP-1 receptor agonists (GLP-1RAs) are pleiotropic medications, initially developed for diabetes, yet with beneficial effects on obesity and cardiovascular disease. Given the rapidly expanding therapeutic use of these agents and emerging preclinical data suggesting immunomodulatory effects, we examined whether GLP-1RA exposure following cancer diagnosis was associated with altered risk of progression to metastatic disease. **Methods:** Utilizing the TriNetX Global Health Research Network, we identified 10,225 patients with stage I-III cancer who initiated GLP-1RA therapy after diagnosis. GLP-1RA-exposed patients were propensity-matched 1:1 to DPP-4 inhibitor controls across seven cancers: breast adenocarcinoma, prostate adenocarcinoma, NSCLC, colorectal adenocarcinoma (CRC), hepatocellular carcinoma (HCC), renal cell carcinoma (RCC), and pancreatic adenocarcinoma. Matching included demographics, BMI, glycemic factors, smoking, comorbidities, screening frequency, oncologic treatments, and concurrent medications. Primary outcome was progression to stage IV disease. Additionally, we used The Cancer Genome Atlas (TCGA) data to assess whether GLP-1R expression correlated with overall survival. **Results:** GLP-1RA exposure demonstrated reduced metastatic progression across 6/7 malignancies, with statistically significant reductions in four cancer types: NSCLC, breast, CRC, and HCC (Table 1). No significant safety signals or increased adverse events were observed in GLP-1RA-exposed patients compared to controls. Additionally, high tumor GLP-1R expression correlated with improved survival across the seven tumors (HR=0.67, 95% CI 0.54-0.83, $p<0.001$), most notably in breast cancer (HR=0.55, 95% CI 0.35-0.87, p=0.011). **Conclusions:** In this large propensity-matched cohort, GLP-1RA initiation after cancer diagnosis was associated with dramatically reduced metastatic progression across multiple solid tumors. Corroborating these clinical findings, elevated GLP-1R expression independently predicted improved overall survival. These findings warrant validation in prospective randomized controlled trials and mechanistic investigation of potential antineoplastic pathways driven by GLP-1RAs. Research Sponsor: None.

Effect of GLP1-1RA exposure compared to DPP-4i exposure on progression of stage I-III cancer to stage IV cancer.

Cancer Type	Matched Pairs (n)	Events GLP-1RA/DPP-4i	Cumulative Incidence (%)	Hazard Ratio (95% CI)	P-value
NSCLC	2,157	215/482	10.0 vs 22.3	0.50 (0.43-0.59)	<0.001
Breast	1,187	121/239	10.2 vs 20.1	0.57 (0.46-0.71)	<0.001
Colorectal	784	105/174	13.4 vs 22.2	0.69 (0.54-0.88)	0.003
HCC	275	52/78	18.9 vs 28.4	0.62 (0.44-0.89)	0.009
Prostate	1,010	83/137	8.2 vs 13.6	0.79 (0.60-1.04)	0.09
RCC	523	75/99	14.3 vs 18.9	0.95 (0.71-1.29)	0.76
Pancreatic	120	28/37	23.3 vs 30.8	0.69 (0.42-1.13)	0.14

Efficacy and safety of pralsetinib in *RET* fusion–positive solid tumors: Data from the TAPISTRY trial. First Author: Chia-Chi Lin, National Taiwan University Hospital, Taipei, Taiwan

Background: Pralsetinib is an oral tyrosine kinase inhibitor that selectively and potently targets oncogenic RET fusion and mutation proteins, present in multiple tumor types. We report results from the phase 2 TAPISTRY study (NCT04589845), a global, open-label, multicohort study evaluating the efficacy and safety of pralsetinib in a cohort of patients with *RET* fusion-positive solid tumors. **Methods:** Eligible patients ≥12 years old with unresectable, locally advanced or metastatic *RET* fusion-positive solid tumors received 400 mg pralsetinib QD until disease progression, loss of clinical benefit, or unacceptable toxicity. Independent review committee (IRC)-assessed objective response rate (ORR) was the primary end point. Key secondary end points included IRC-assessed duration of response (DOR) and progression-free survival (PFS), and overall survival (OS). **Results:** Forty-six patients were enrolled and received ≥1 pralsetinib dose; 78% had ≤1 prior line of therapy in the metastatic setting. Median age was 56 y (range: 12-79); 61% were male. Median treatment duration was 14.3 mo (range: 0.7-31.5). Cancers included thyroid (n=18, 39%); colorectal (n=9, 20%); head and neck (n=4, 9%); pancreatic (n=4, 9%); hepatobiliary (n=3, 7%); CNS, sarcoma, and neuroendocrine and adrenal (n=2, 4% each); gastroesophageal (n=1, 2%); and unknown primary origin (n=1, 2%). ORR for the efficacy evaluable population (n=39) was 67% (95% CI: 50, 81; Table), with 5 (13%) CRs and 21 (54%) PRs. Intracranial response was observed in 1/2 (50%) patients with baseline CNS metastases. All patients experienced treatment-related adverse events (TRAEs); 33/46 (72%) reported TRAEs grade ≥3. The most common TRAEs included anemia (n=18; 39%), increased AST (n=16; 35%), and decreased neutrophil count (n=13; 28%). Hypertension was reported in 11 (24%) patients, with 3 (7%) reporting grade ≥3. Safety results were consistent with the known pralsetinib profile, with no new signals. **Conclusions:** Pralsetinib demonstrated robust and durable activity against *RET* fusion-positive solid tumors, with an ORR of 67%. These data validate RET fusions as a tissue-agnostic target with sensitivity to RET inhibition, suggesting therapeutic utility of pralsetinib. Clinical trial information: NCT04589845. Research Sponsor: Rigel Pharmaceuticals, Inc.

Efficacy summary by tumor type.

	Overall (N=39)	Thyroid (n=16)	Pancreatic (n=3)	Colorectal (n=8)	Hepatobiliary (n=3)	Head and Neck (n=3)
ORR, % (95% CI)	67 (50, 81)	81 (54, 96)	67 (9, 99)	38 (9, 76)	33 (1, 91)	100 (29, 100)

Efficacy and safety of larotrectinib in patients with non-primary central nervous system *TRK* fusion cancer: An updated analysis. First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Larotrectinib (laro) is the first-in-class, highly selective TRK inhibitor approved for tumor-agnostic use in patients (pts) with TRK fusion cancer based on a robust and durable objective response rate in pts with various cancers. Here, we report updated long-term efficacy and safety in adult and pediatric pts treated with laro with non-primary central nervous system (CNS) TRK fusion cancer. **Methods:** Pts from 3 clinical trials (NCT02637687 [SCOUT], NCT02576431 [NAVIGATE], NCT02122913) were included. Laro was administered at 100 mg twice daily (BID) and 100 mg/m^2 (max 100 mg) BID in most adult and pediatric pts, respectively. Responses were independent review committee-assessed (RECIST v1.1). Pts enrolled in SCOUT could stop laro in the absence of on-treatment progression ("wait-and-see") and remain on trial. If pts were re-treated due to progression, response was assessed by investigators. Data cutoff: July 20, 2025. **Results:** In total, 304 pts were treated; 25 had baseline CNS metastases. There were 28 tumor types, including soft tissue sarcoma (24%), infantile fibrosarcoma (16%), lung (11%), and thyroid (10%). *NTRK* gene fusions were detected by next-generation sequencing (NGS) in 266 (88%) pts. Overall response rate was 65% (95% confidence interval [CI] 59–70) with 61 (20%) complete responses (CR), 18 (6%) pathological CR, 118 (39%) partial responses (PR), 55 (18%) stable disease (SD), 32 (11%) progressive disease (PD), and 20 (7%) not evaluable/undefined. Median duration of treatment was 19 months ([mo] range 0–111). At data cutoff, 52 pts (17%) remained on trial (either on treatment or in "wait-and-see"). Median time to response was 1.8 mo (range 0.9–80.3). Median duration of response (DoR), progression-free survival (PFS), and overall survival (OS) were 42 mo (95% CI 31–59), 26 mo (95% CI 19–35), and not reached (95% CI 89–not estimable), respectively, at median follow-ups of 54, 52, and 65 mo. The 5-year rates for DoR, PFS, and OS were 41% (95% CI 33–49), 33% (95% CI 27–40), and 61% (95% CI 55–67), respectively. Fifty-seven pediatric pts entered a first "wait-and-see" period (median duration 24 mo [range 0–75+]). Of these, 38 exited the "wait-and-see" period. By investigator assessment, 20 pts had PD and resumed treatment (with 6 CR, 5 PR [including 2 pending confirmation], 7 SD, 2 unevaluable/undefined). The other 18 pts discontinued laro permanently but were all alive at data cutoff. Treatment-related adverse events (TRAEs) were mainly worst Grade 1/2 (n=189; 62%). Worst Grade 3/4 TRAEs occurred in 72 (24%) pts. Five (2%) pts discontinued due to TRAEs. **Conclusions:** Laro continues to demonstrate rapid and durable responses, extended survival, clinical benefit, and a favorable safety profile in pts with TRK fusion cancer. These data support the wider adoption of NGS panels that include *NTRK* gene fusions to identify pts who may benefit from TRK inhibitor therapy. Clinical trial information: NCT02637687, NCT02576431, NCT02122913. Research Sponsor: Healthcare and Loxo Oncology, Inc., a wholly owned subsidiary of Eli Lilly and Company.; was supported by the National Cancer Institute/National Institutes of Health P30CA008748, 1R01CA226864-01A1 grants, and Nonna's Garden.

BMS-986504 in patients (pts) with advanced solid tumors with homozygous *MTAP* deletion (*MTAP*-del): Exploratory pharmacodynamic (PD) and biomarker analyses from CA240-0007. First Author: Jason Timothy Henry, Sarah Cannon Research Institute at HealthONE, Denver, CO

Background: The MTA-cooperative PRMT5 inhibitor BMS-986504 selectively binds to the PRMT5-MTA complex, a synthetic lethal target in *MTAP*-del cancer cells, while sparing *MTAP*–wild-type normal cells. In the phase 1 CA240-0007 study, BMS-986504 was well tolerated and had antitumor activity in pts with *MTAP*-del advanced solid tumors (ORR, 23%; median DOR, 10.5 mo). BMS-986504 also demonstrated dose-dependent reductions in plasma symmetric dimethylarginine (SDMA) levels, a PD biomarker of PRMT5 inhibition. Here, we report expanded PD and genomic analyses and initial results of exploratory proteomic analyses from CA240-0007. **Methods:** Pts with advanced, unresectable, or metastatic solid tumors with homozygous *MTAP*-del received BMS-986504 (50–800 mg) in 3-wk cycles. Analyses of SDMA levels and proteomic profiles from paired plasma samples (baseline and C2D1) were performed using mass spectrometry and SomaScan 11K, respectively. Tumor genomic information was extracted from local pathology reports. ORR was assessed per RECIST v1.1. **Results:** Among 78 pts with paired samples at data cutoff (22 Sept 2025; median f/u, 15.9 mo), dose-dependent reductions were seen in plasma SDMA levels, with the greatest reductions at 400 mg QD (median, 60.3%; n = 31) and 600 mg QD (median, 60.3%; n = 23). Proteomic pathway enrichment analysis demonstrated downregulation of PI3K/Akt/mTOR, Myc target, cell cycle, and DNA damage repair (DDR) pathways with BMS-986504 on C2D1 (n = 87), consistent with the expected effect of PRMT5 inhibition; a trend toward deeper modulation of PRMT5-regulated pathways was observed at higher doses. No proteins at baseline (n = 94) were found to be significantly associated with ORR (false discovery rate > 0.05). Responses in clinically evaluable pts with NSCLC (n = 33) or PDAC (n = 35) were observed regardless of *EGFR*, *KRAS*, or *TP53* status. In pts with NSCLC, *STK11* and *SMARCA4* alterations were numerically higher in nonresponders. No gene alterations were associated with response in PDAC, except *GABRA6* alterations (n = 2, both responders). A trend toward higher ORRs was seen in pts with alterations in DDR genes (*CHEK2, FANCD2, XRCC4*, and/or *MSH2*), consistent with the role of PRMT5 in DDR via regulation of mRNA splicing. ctDNA analysis will be presented. **Conclusions:** BMS-986504 demonstrated robust dose-dependent PD effects in pts with advanced solid tumors in plasma SDMA and proteomic analyses. Downregulation of PRMT5-regulated pathways was observed with BMS-986504 treatment. Response was seen regardless of *EGFR, KRAS*, and *TP53* alterations in NSCLC or PDAC, and DDR gene alterations were associated with improved response. These findings further support the MOA of BMS-986504 and its ongoing investigation in the phase 2/3 MountainTAP-9, -29, and -30 studies as a potential treatment option in pts with *MTAP*-del advanced solid tumors. Clinical trial information: NCT05245500. Research Sponsor: Bristol Myers Squibb.

3147 Poster Session

Fast-TRACKing precision oncology for rare cancers: A national decentralized trial offering comprehensive genomic profiling and a molecular tumor board. First Author: Jim Palma, TargetCancer Foundation, Cambridge, MA

Background: The TargetCancer Foundation TCF-001 TRACK study (Target RAre Cancer Knowledge, NCT04504604) initiated on Oct 01, 2020, is a fully remote, advocacy-driven decentralized precision trial seeking to evaluate the clinical impact of utilizing comprehensive genomic profiling (CGP) reviewed by a molecular tumor board (MTB) for patients (pts) with rare cancers. **Methods:** Pts were remotely enrolled/consented. Blood samples were collected via mobile phlebotomy and tested with FoundationOne Liquid CDx; tissue biopsies (TBx) were tested using FoundationOne CDx ± laboratory developed (LD) FoundationOne RNA or LD FoundationOne Heme. Liquid biopsy testing (LBx) included algorithmic predictions for clonal hematopoiesis (CH). MTB reviewed results and provided recommendations. **Results:** As of Oct 01, 2025, 230 pts from 46 US states were enrolled with evaluable results; 76% (175/230) had TBx and LBx, 22% LBx, and 2% TBx biopsies. MTB review was completed for 226 pts. Median age was 57 years (interquartile range [IQR]: 47,66); > 60 tumor types were represented: cholangiocarcinoma (35%), gastrointestinal (19%), soft tissue-related sarcomas (17%), brain (14%), and others (15%). First on-study TBx CGP (n=173) showed microsatellite instability high in 2%, homologous repair deficiency-signature in 2%, and median tumor mutational burden (TMB) of 1.3 mut/Mb (IQR: 0.8,3.6; 5 pts ≥ 10 mut/Mb). In LBx (n=57), ctDNA tumor fraction (TF) was ≥1% in 28% of pts; median blood TMB was 1.3 (IQR: 0,2.5; 1 pt ≥ 10 mut/Mb). Overall, 95% (219/230) of tumors had >1 pathogenic alteration; TBx CGP detected alterations in 96% (172/179), most frequently *TP53* (35%), *CDKN2A* (29%), *CDKN2B*(21%), *KRAS* (19%), *MTAP* (17%), and *TERT* (14%). LBx CGP detected alterations in 85% (192/225), with tumor-derived (TD) variants in *KRAS* (11%), *IDH1* (7%), and *CDKN2A* (6%). *TP53* (31%) included both TD and CH variants, while *DNM3TA* (30%), *ATM* (10%), *TET2* (10%), and *CHEK2* (8%) were mostly CH. In brain tumors, 52 variants from 28 pts with LBx identified 45 CH, 4 germline, and 3 TD. Across all tumor types, 9% (20/230) had biomarkers for FDA-approved tissue-agnostic therapies. This includes *ERBB2* amplification (2% overall), which is often correlated with *HER2* immunohistochemistry positivity. LBx sensitivity for DNA tissue-detected clonal SVs and rearrangements was 85% (95% CI: 0.74,0.92) when ctDNA TF≥1%; 24% (95% CI: 0.19,0.29) when <1%. Pathogenic fusions detected by RNA sequencing were not detected by DNA in 33% of cases (9/27). **Conclusions:** CGP identified pathogenic alterations in nearly all rare cancer patients, with tissue-agnostic biomarkers in 9%. RNA sequencing adds diagnostic yield. CH in liquid biopsies underscores need for expert MTB interpretation. TRACK, a first-of-its-kind national decentralized trial, provides a scalable framework for equitable precision oncology access. Clinical trial information: NCT04504604. Research Sponsor: TargetCancer Foundation; Foundation Medicine.

3148 **Poster Session**

Multi-modal molecular profiling of CDH1 and CLDN18.2 to identify predictive biomarkers for zolbetuximab efficacy in patients with advanced gastric adenocarcinoma: The ZOL-C3 study. First Author: Shuhei Suzuki, Department of Clinical Oncology, Yamagata University, Yamagata, Japan

Background: Zolbetuximab is a chimeric monoclonal antibody designed to bind to claudin 18.2 (CLDN18.2) and induce antibody-dependent cell-mediated cytotoxicity (ADCC). Although phase 3 trials established its efficacy in CLDN18.2-positive advanced gastric adenocarcinoma (GAC), robust predictive biomarkers beyond protein expression remain an unmet need. We investigated how epithelial-mesenchymal transition (EMT), mediated by CDH1 alterations and the tumor mutational burden (TMB), modulates the therapeutic target and affects zolbetuximab-mediated ADCC efficacy. **Methods:** This study employed a multi-layered integrative framework across four independent datasets to cross-validate genomic, transcriptomic, and phenotypic findings: (1) mechanistic characterization using the TCGA-STAD cohort (n=375); (2) the genomic screening of 2,483 patients with GAC in the Japanese national database (C-CAT), which identified 49 treated with zolbetuximab-containing regimens; (3) a spatial transcriptomic evaluation (10× Genomics Visium platform, GSE251950); and (4) immunohistochemical (IHC) validation of CLDN18.2 in 36 institutional GAC patients. The trial is registered at UMIN-CTR (UMIN000060223), a WHO ICTRP primary registry. **Results:** In the TCGA cohort, CDH1 low-expression was significantly associated with 3.2-fold lower CLDN18 mRNA levels than in the high-expression group ($p < 0.001$). CDH1 expression was strictly regulated by promoter methylation ($p < 0.001$), whereas CLDN18 down-regulation in CDH1-low tumors appeared to be driven by non-epigenetic EMT pathways. Spatial transcriptomics revealed a spatial correlation between CDH1 and CLDN18 mRNAs within the malignant epithelial compartment ($p < 0.001$). The objective response rate within the zolbetuximab-treated C-CAT subset was 22.2%. TMB was markedly lower in responders than in non-responders (median 1.82 vs. 4.0 mut/Mb; p = 0.050). Furthermore, patients without CDH1 single nucleotide variants had higher ORR (p = 0.086). Institutional IHC validation revealed a superior response in cases that retained membranous CDH1 expression to that in cases with the loss of epithelial integrity (100% vs 50% ORR; p=0.088). **Conclusions:** These results demonstrate that CDH1/E-cadherin integrity and low TMB are critical co-determinants of CLDN18.2 expression and zolbetuximab efficacy. Maintenance of the epithelial phenotype appears to be essential for optimal zolbetuximab-mediated ADCC. The integration of comprehensive molecular profiling, including the CDH1 status and TMB, may significantly refine patient selection, with a shift from simple target positivity to a more biological enrichment strategy for zolbetuximab therapy. Research Sponsor: None.

Clinical outcomes of patients with cell cycle alterations by treatment type: The MD Anderson Cancer Center IMPACT 2 study. First Author: Abhijit Chakraborty, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Cell cycle pathway alterations are a hallmark of cancer. Disruption of cell cycle checkpoints results in genomic instability, uncontrolled proliferation and tumor progression to aggressive and treatment-resistant phenotypes. We report the clinical outcomes of patients with cell cycle pathway alterations treated in the IMPACT 2 study (2014-2023; NCT02152254). **Methods:** Patients with advanced cancer underwent tumor biopsy and molecular profiling (CLIA-certified lab). Pathway analysis was conducted using the *maftools* R package. Cell cycle pathway alterations were defined as those involving the *CCND1*, *CCND2*, *CCNE1*, *CDK4*, *CDK6*, *CDKN2A*, *CDKN2B*, and *RB1* genes. Cases were discussed at Molecular Tumor Board meetings. Patients were treated on clinical trials with investigational agents that included matched targeted therapies (MTTs) when available. We analyzed the following outcomes by treatment type (MTT vs. non-matched targeted therapy [NTT] and immunotherapy [IO] vs. non-IO): objective response rate (complete response + partial response), clinical benefit rate (CBR; ORR + stable disease≥4 months), progression-free survival (PFS), and overall survival (OS). **Results:** Of 491 treated patients with targetable alterations, 157 (32.0%) had cell cycle pathway alterations (median age, 61 years [range, 21-82]; female, 46.5%; ECOG performance status 1, 85.4%; median number of prior therapies, 3 [range, 0-9]; liver metastases, 40.8%; >2 metastatic sites, 36.3%; high LDH, 33.1%; low albumin, 10.8%). The most common cancers were sarcoma (19.7%), other gastrointestinal (17.2%), head and neck (14.0%), lung (9.6%), and breast (8.3%). Other tumor characteristics included PD-L1 ≥1%, 45.6% (41/90); MSI-H, 2.0% (2/102); and TMB-H, 13.0% (13/100). Concomitant pathway alterations were TP53 (67.5%), PI3K (29.9%), and RTK-RAS (47.1%). MTT targeted CDK4/6, n=9; BET, n=2; ATR, n=1; PKMYT1, n=1; and ACAT, n=1. Clinical outcomes are shown in the Table. **Conclusions:** Very few investigational therapies that target the cell cycle pathway were available. No differences were noted in tumor response, PFS, or OS by type of therapy, likely owing to the limited antitumor activity of the MTTs and the complexity of targeting this pathway. Novel and effective MTTs are needed for tumors with cell cycle dysregulation. Clinical trial information: NCT02152254. Research Sponsor: National Cancer Institute; P30 CA016672; Mr. and Mrs. Steven Mckenzie's Endowment; Katherine Russell Dixie's Distinguished Professorship Endowment; Jamie's Hope and Mrs. and Mr. James Ritter; Foundation Medicine; TEMPUS AI.

Clinical outcomes of patients with PI3K pathway alterations by treatment type: The MD Anderson Cancer Center IMPACT 2 study. First Author: Apostolia Maria Tsimberidou, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The phosphatidylinositol 3-kinase (PI3K) pathway regulates cell growth, metabolism, and survival and is involved in immune modulation. Alterations in PI3K signaling drive tumor progression and drug resistance in advanced cancers and are associated with poorer prognosis. Herein, we report the clinical outcomes of patients with PI3K pathway alterations treated in the IMPACT 2 study (2014-2023; NCT02152254). **Methods:** Patients with advanced cancer underwent tumor biopsy and molecular profiling (CLIA-certified lab). Pathway analysis was conducted using the *maftools* R package. PI3K pathway alterations were defined as those involving the *PI3K, AKT1, AKT2, AKT3, MTOR, PIK3CA, PIK3CB, PIK3R1, PTEN, TSC1,* and *TSC2* genes. Cases were discussed at Molecular Tumor Board meetings. Patients were treated on clinical trials with investigational agents that included matched targeted therapies (MTTs) when available. We analyzed the following outcomes by treatment type (MTT vs. non-matched targeted therapy [NTT] and immunotherapy [IO] vs. non-IO): objective response rate (ORR; complete response + partial response), clinical benefit rate (CBR; ORR + stable disease ≥4 months), progression-free survival (PFS), and overall survival (OS). **Results:** Of 491 treated patients with targetable alterations, 133 (27.1%) had PI3K pathway alterations (median age, 60.3 years [range, 20.5-79.8]; female, 60.9%; ECOG performance status 1, 85.7%; median number of prior therapies, 3 [range, 0-14]; liver metastases, 42.9%; >2 metastatic sites, 44.3%; high lactate dehydrogenase levels, 42.1%; low albumin level, 9%). The most common tumor types were breast cancer (18%), colorectal cancer (15%), and sarcoma (12%). Concomitant pathway alterations were TP53 (49.6% of patients), RTK/RAS (43.6%), and cell cycle (35.3%). Other tumor characteristics included PD-L1≥1%, 40.5% (32/79); MSI-H, 2.2% (2/89); and TMB-H, 10.3% (9/87). MTT included mTOR inhibitors, n=17; AKT inhibitors, n=5, and PI3K inhibitors, n=4. Clinical outcomes are shown in the Table. **Conclusions:** Taking into consideration the relatively limited use of AKT and PI3K inhibitors compared with mTOR inhibitors, no differences were noted in tumor response, PFS, or OS, by type of treatment. Other contributing factors may include the biological complexity of targeting this pathway, the small number of patients and/or the limited availability and antitumor activity of MTTs. Clinical trial information: NCT02152254. Research Sponsor: Foundation Medicine; Tempus AI; Mr. and Mrs. Steven Mckenzie's Endowment; Katherine Russell Dixie's Distinguished Professorship Endowment; Jamie's Hope and Mrs. and Mr. James Ritter; National Cancer Institute; P30 CA016672.

Clinical outcomes of patients with RTK-RAS pathway alterations by treatment type: The MD Anderson Cancer Center IMPACT 2 study. First Author: Mehmet A. Baysal, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The receptor tyrosine kinase (RTK)-RAS signaling axis comprises distinct membrane receptors and downstream effectors that regulate cell proliferation and survival. Alterations in this pathway drive carcinogenesis and are associated with poor prognosis. We analyzed the outcomes of patients with RTK-RAS pathway alterations enrolled in the IMPACT 2 study (2014-2023; NCT02152254). **Methods:** Patients with advanced cancer underwent tumor biopsy and molecular profiling (CLIA-certified lab). Pathway analysis was conducted using the *maftools* R package. RTK-RAS pathway alterations were defined as those involving *EGFR, ERBB2, ALK, MET, KRAS, NRAS, BRAF*, and *MAP2K1/2* genes. Cases were discussed at Molecular Tumor Board meetings. Patients were treated in clinical trials with investigational agents, including matched targeted therapies (MTTs) when available. We analyzed the following outcomes by treatment type (MTT vs. non-matched targeted therapy [NTT] and immunotherapy [IO] vs. non-IO): objective response rate (ORR; complete response + partial response), clinical benefit rate (CBR; ORR + stable disease≥4 months), progression-free survival (PFS), and overall survival (OS). **Results:** Of 491 treated patients with targetable alterations, 216 (44%) had RTK-RAS pathway alterations (median age, 62.3 years [range, 21-80]; female, 54.1%; ECOG performance status 1, 90.3%; median number of prior therapies, 3 [range, 0-10]; liver metastases, 46.3%; > 2 metastatic sites, 34.7%; high LDH, 37.0%; low albumin level, 11.1%). The most common cancers were gastrointestinal (40.3%), head/neck (10.2%), and lung (10.2%). Other tumor characteristics included PD-L1≥1%, 43.6% (58/133); MSI-H, 1.3% (2/153); and TMB-H, 10.7% (16/150). Concomitant pathway alterations were TP53 (62.5%), PI3K (26.9%), and cell cycle (34.3%) pathways. MTT targeted EGFR, n = 8; FGFR, n = 10; HER2, n = 6; BRAF+MEK, n = 3; ALK, n = 1; and MEK, n = 4 among others (n = 24). Clinical outcomes are shown in the Table. **Conclusions:** The ORR was 14.6% in IO-treated patients vs. 5% in the non-IO-treated group (p = 0.049), although the difference was not significant. No differences in PFS or OS were observed by therapy type in patients with RTK-RAS pathway alterations. Novel MTTs (i.e., KRAS inhibitors) that were unavailable during the study period may improve the outcomes of these patients. Identification of molecular subsets benefiting from MTT is needed. Clinical trial information: NCT02152254. Research Sponsor: National Cancer Institute; Foundation medicine; TEMPUS AI; Katherine Russell Dixie's Distinguished Professorship Endowment; Jamie's Hope and Mrs. and Mr. James Bitter.

Clinical outcomes of patients with TP53 pathway alterations by treatment type: The MD Anderson Cancer Center IMPACT 2 study. First Author: Jacopo Venturini, Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: TP53 pathway alterations are found in over 50% of human cancers, with variable frequency across tumor types. They are associated with aggressive tumor biology, increased metastatic potential, and poor prognosis. Herein, we report the clinical outcomes of patients with TP53 pathway alterations treated in the IMPACT 2 study (2014-2023; NCT02152254). **Methods:** Patients with advanced cancer underwent tumor biopsy and molecular profiling (CLIA-certified lab). Pathway analysis was conducted using the *maftools* R package. TP53 pathway alterations were defined as those involving the *TP53*, *ATM*, *CHEK1*, *CHEK2*, *MDM2*, and *MDM4* genes. Patients were treated on clinical trials with investigational agents that included matched targeted therapies (MTTs) when available. MTT included anti-vascular endothelial growth factor (VEGF) targeted therapy, as previously published (PMID: 27466356). We analyzed the following outcomes by treatment type (MTT vs. non-matched targeted therapy [NTT] and immunotherapy [IO] vs. non-IO): objective response rate (ORR; complete response + partial response), clinical benefit rate (CBR; ORR + stable disease≥4 months), progression-free survival (PFS), and overall survival (OS). **Results:** Of 491 treated patients with targetable alterations, 278 (56.6%) had p53 pathway alterations (median age, 60.1 years [range, 20.5-81.7]; female, 51.4%; ECOG performance status 1, 86.0%; median number of prior therapies, 3 [range, 0-11]; liver metastases, 42.2%; >2 metastatic sites, 36.0%; high lactate dehydrogenase level, 41.0%; low albumin level, 9%). The most common tumors were colorectal (21.2%), sarcoma (13.7%), other gastrointestinal (12.2%), and breast (8.6%). Immune markers included PD-L1≥1%, 47.3% (78/165); MSI-H, 1% (2/199); and TMB-H, 10.5% (19/181). Concomitant pathway alterations were RTK-RAS (48.6%), PI3K (24.8%), and cell cycle (38.1%) pathways. MTT included VEGF/VEGFR inhibitors, N=57; MDM2 inhibitors, N=4; and TP53 activator, N=1. Clinical outcomes are shown in the Table. **Conclusions:** Median OS was significantly longer in patients with TP53 pathway alterations treated with IO compared with non-IO regimens. Considering the limited availability of TP53-targeted agents, no differences in clinical outcomes were noted for MTT compared with NTT. Further analyses are warranted to elucidate the molecular substrates underlying immunotherapy benefit. Clinical trial information: NCT02152254. Research Sponsor: National Cancer Institute; P30 CA016672; Foundation Medicine; Tempus AI; Katherine Russell Dixie's Distinguished Professorship Endowment; Jamie's Hope and Mrs. and Mr. James Ritter.

Impact of dual inhibition of iNOS and COX2 on antitumor immunity and response to immune checkpoint blockade in hepatocellular carcinoma. First Author: Yuzhen Li, University of Pittsburgh, Department of Surgery, Pittsburgh, PA

Background: Hepatocellular carcinoma (HCC) remains a leading cause of cancer-related mortality worldwide. Although immune checkpoint blockade (ICB) benefits a subset of patients, efficacy is often limited by an immunosuppressive tumor microenvironment. Inducible nitric oxide synthase (iNOS/NOS2) and cyclooxygenase-2 (COX2) are inflammation-associated enzymes implicated in immune regulation. We hypothesized that inhibition of these pathways enhances antitumor immunity and improves responsiveness to immune checkpoint therapy in HCC. **Methods:** Tumor tissues from 75 patients with resected hepatocellular carcinoma (HCC) were analyzed by immunohistochemistry for NOS2, COX2, and CD8 to assess expression levels and spatial correlations. In parallel, an orthotopic murine HCC model was established by intrahepatic injection of 7.5×10^5 RIL-175 cells (n = 6–10 mice per group). Mice were treated with vehicle control, selective NOS2 inhibition (1400W), COX2 inhibition (celecoxib), anti–PD-L1, or combination regimens including triple therapy. After two weeks of treatment, tumors were harvested for immune profiling, including flow cytometry, spatial imaging, plasma cytokine analysis, and CITE-seq. In vitro, splenocytes isolated from B6 mice were treated with prostaglandin E2 (PGE2) or the nitric oxide donor DETA-NONOate, and expression of CD226 and TIGIT was quantified by flow cytometry. **Results:** High intratumoral NOS2 expression was associated with inferior overall survival in resected HCC patients (HR 3.65, p=0.0011), with further worsening observed in tumors co-expressing NOS2 and COX2 (HR 9.31, $p<0.0001$). In murine HCC, combined iNOS and COX2 inhibition significantly reduced tumor burden and promoted intratumoral accumulation of $CD8^+$ and $CD4^+$ T cells, accompanied by increased B-cell recruitment and elevated circulating IL-2 and IFN-γ. Triple therapy with dual enzyme inhibition plus anti–PD-L1 resulted in superior tumor control and prolonged survival. Single-cell transcriptomic analysis comparing control, dual inhibition, and triple-treatment groups revealed a progressive enhancement of $CD8^+$ T-cell activation states, characterized by increased expression of activation-associated markers and reduced expression of inhibitory receptors. Dual and triple therapy induced upregulation of CD226 and downregulation of TIGIT in $CD8^+$ T cells, reflecting enhanced antitumor effector function. In vitro, nitric oxide and prostaglandin E2 directly impaired $CD8^+$ T-cell function, as evidenced by reduced CD226 and increased TIGIT expression. **Conclusions:** iNOS and COX2 cooperatively establish an immunosuppressive inflammatory program in HCC that limits $CD8^+$ T-cell–mediated antitumor immunity and response to checkpoint blockade. Dual targeting of these pathways represents a promising strategy to enhance immunotherapy efficacy in HCC. Research Sponsor: UPMC enterprise.

3154 **Poster Session**

Safety, pharmacokinetics (PK), pharmacodynamics (PD), and antitumor activities of FL115, a novel IL-15 superagonist, from the first-in-human study in patients with locally advanced/metastatic solid tumors. First Author: Carlos Roberto Becerra, Hoag Family Cancer Institute, Newport Beach, CA

Background: FL115 is an engineered IL-15/IL15Rα-Fbody fusion protein, in which Fbody is a single-chain Fc designed to eliminate classical Fc effects including ADCC/CDC/ADCP while retaining FcRn engagement. It aims to enhance anti-tumor immunity via IL-15-mediated signaling on NK and CD8+ T cells while minimizing complexity from Fc. **Methods:** The first-in-human, dose-escalation study of FL115 (NCT06130722) evaluated the safety, tolerability, pharmacokinetics, pharmacodynamics, and antitumor activity of FL115 in adult patients with advanced solid tumors. FL115 monotherapy was administered intravenously once weekly. **Results:** 11 patients (7F, 4M) were enrolled, median age 64, who had progressed on prior systemic therapies across four dose cohorts (3–60 μg/kg). MTD was not reached. No SAEs related to FL115 or DLT were observed. Most TRAEs were Grade 1–2 and aligned with the known safety profile of cytokine-based therapies and underlying conditions of patients. Only three reversible TRAEs occurred, including transient Grade 3 alanine aminotransferase elevation, Grade 3 headache, and Grade 4 neutropenia. PK was dose-dependent, with half-life at 2.1-3.1 hours. Four patients had Stable Disease per imaging (DCR 36.3%). Dose-dependent expansion of lymphocytes was observed, with average absolute lymphocyte count (ALC) of 1257 cells/μl at baseline, and peak ALC count of 2371 cells/μl post treatment, mainly from increase in NK cells and CD8+T cells. One patient (Cervical Cancer) had Stable Disease from 1st dose at July 2024 (ALC of 1100 cells/μl) to study completion (ALC of 1900 cells/μl in August 2025). FL115 treatment led to significant transient cytokine release in peripheral blood: at 3 μg/kg, peak interferon-γ level reached 3730 pg/ml with IL-6 at 0.8 pg/ml, suggesting specific targeting of NK and T cells. An essentially identical Phase 1 study of FL115 was conducted in China, in which similar trends were observed; two patients remained on treatment with confirmed partial responses lasting 32 and 24 weeks, respectively. **Conclusions:** FL115 is the first IL-15 superagonist as monotherapy has shown a favorable safety profile and promising signs of durable antitumor activities in heavily pretreated patients, along with significant and sustained expansion of NK and T cell population and unique robust transient induction of interferon-γ. A Phase II study of FL115 with Bacillus Calmette-Guérin in patients with nonmuscle invasive bladder cancer (NCT07122414) and a Phase Ib study of FL115 (IV) in combination with an anti-PD-1 antibody in solid tumor patients (NCT07131202) are ongoing, and a Phase I study of FL115 subcutaneous injection will be initiated soon (IND submitted). Clinical trial information: NCT # 06130722. Research Sponsor: Furlong.

TPS3155 **Poster Session**

A phase 1/2, first-in-human, open-label, dose-escalation and -expansion study of TAK-188, a novel antibody-drug conjugate (ADC) targeting $CCR8^+$ regulatory T cells, in adult patients with locally advanced or metastatic solid tumors. First Author: Anthony J. Olszanski, Fox Chase Cancer Center, Philadelphia, PA

Background: Regulatory T cells (Tregs) are key contributors to an immunosuppressive tumor microenvironment (TME). Their abundance in solid tumors is often linked to poor patient prognosis, decreased overall survival, and resistance to immunotherapy. Tumor-infiltrating Tregs express high levels of chemokine receptor CCR8, making CCR8 an attractive target for immunotherapy. TAK-188 is a first-in-class anti-CCR8 ADC that aims to enhance patients' own antitumor activity by selectively eliminating CCR8-positive Tregs within the TME. It uses a novel amanitin payload capable of killing both actively dividing and non-dividing cells and is linked to the antibody via a cleavable linker. The nonclinical toxicology profile demonstrated monitorable and partially-to-completely reversible toxicities at doses exceeding projected clinically efficacious exposures. Preclinical evaluation of TAK-188 showed robust and deep depletion of $CCR8^+$ cells *in vitro* and *in vivo*, and demonstrated anti-tumor activity as a single agent in non-clinical models (Casson et al. AACR 2026). **Methods:** This phase 1/2 study (NCT07205718) is enrolling adult patients with locally advanced or metastatic solid tumors known to express high levels of CCR8 on Tregs in the TME (gastroesophageal adenocarcinoma [GC] and esophageal squamous cell carcinoma [ESCC], pancreatic ductal adenocarcinoma, non-squamous and squamous non-small cell lung cancer [NSCLC], head & neck SCC [SCCHN], or colorectal cancer), and whose disease has progressed on, or are intolerant to, all standard therapies. Eligible patients must have Eastern Cooperative Oncology Group performance status $\leq$1 and radiographically measurable disease per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1. In phase 1, TAK-188 is intravenously administered weekly at escalating dose levels following a Bayesian Optimal Interval design, to determine the recommended phase 2 dose (RP2D) and dosing schedules for the cohort-expansion phase. The primary objective is to determine the safety and tolerability of TAK-188 in phase 1 and to assess the preliminary efficacy in phase 2 in NSCLC, SCCHN and GC. Secondary objectives include characterization of the RP2D and pharmacokinetic parameters for TAK-188, changes in T cell populations (abundance and ratio of Tregs and effector T cells) within the tumor post-treatment, and preliminary efficacy in select cancer types. Exploratory objectives include the impact of TAK-188 on $CCR8^+$ Tregs, molecular response determined by circulating tumor DNA (ctDNA) analysis, and changes in cytokines and chemokines in peripheral blood. The study plans to enroll up to 223 patients in the USA (47 patients across 15 sites for dose-escalation; 62–176 patients across ~35 sites in cohort-expansion). Clinical trial information: NCT07205718. Research Sponsor: Takeda Development Center Americas, Inc. (TDCA), Cambridge, MA, USA.

TPS3156 Poster Session

A phase 1 study of HWK-007, a next-generation, protein tyrosine kinase 7 (PTK7)–targeted antibody-drug conjugate (ADC), in patients with advanced solid tumors. First Author: Manish R. Sharma, The START Center for Cancer Research - Midwest, Grand Rapids, MI

Background: PTK7 is a pseudokinase expressed during embryogenesis and down-regulated in normal adult tissue. Aberrant overexpression of PTK7 has been reported in up to 70% of solid tumors and is associated with tumor progression, metastasis, chemoresistance, and poor prognosis. A previous analysis demonstrated particularly high *PTK7* expression in non-small cell lung cancer (NSCLC), endometrial carcinoma (EC), and ovarian cancer (OC), across histologic subtypes and disease stages, making PTK7 an attractive therapeutic target with cross-indication applicability (Matulonis et al. AACR-NCI-EORTC 2025, Poster C040). Results from early clinical trials of cofetuzumab pelidotin, a PTK7-targeted, auristatin-based ADC, showed promising clinical activity. HWK-007 is a next-generation, PTK7-targeted ADC comprising an Fc effector-attenuated IgG1 antibody conjugated to the DNA topoisomerase I inhibitor (TOP1i) CPT116. It was designed using novel bioconjugation and advanced linker–payload technologies that enhance intracellular delivery and minimize systemic release of unconjugated TOP1i. This first-in-human, phase 1 trial evaluates HWK-007 in patients with advanced or metastatic solid tumors. **Methods:** This multicenter, open-label, single-arm, phase 1 dose-escalation (a)/expansion (b) trial is enrolling patients aged ≥18 years with advanced or metastatic NSCLC (non-squamous, epidermal growth factor receptor–wild-type [*EGFR*wt]), EC (all histologies), or epithelial OC (all histologies). Patients with NSCLC or EC must have prior treatment with platinum-based chemotherapy and a PD-(L)1 inhibitor, if eligible. Patients with OC must have platinum-resistant disease and prior treatment with standard-of-care therapy. All patients must have measurable disease per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 (except in the OC dose-escalation cohorts in which patients with non-target lesions per RECIST and CA125 ≥2 times ULN are permitted), Eastern Cooperative Oncology Group performance status 0 or 1, and no prior treatment with a TOP1i-containing ADC. Patients with clinically active brain metastases or a history of pneumonitis/interstitial lung disease are ineligible. In phase 1a, patients are sequentially assigned to HWK-007 dose levels (DLs; administered intravenously, once every three weeks) using a Bayesian Optimal Interval design (toxicity threshold, 25%), with potential backfill. Backfill cohorts are enriched for patients with *EGFR*wt NSCLC. Primary endpoints are safety, maximum tolerated dose, and recommended dose for expansion cohorts (phase 1a); and safety and objective response rate (phase 1b). Secondary endpoints include pharmacokinetics and preliminary efficacy outcomes. Recruitment is underway; planned enrollment is up to 226 patients. Clinical trial information: NCT07444814. Research Sponsor: None.

TPS3157 Poster Session

A phase 2 study of telisotuzumab adizutecan (ABBV-400; Temab-A) in patients with advanced solid tumors harboring *MET* amplification. First Author: Manish R. Sharma, The START Center for Cancer Research – Midwest, Grand Rapids, MI

Background: *MET* amplification is a rare alteration occurring at a rate of 0.06%–4.2%, in different solid tumor types across genomic databases. It is associated with poor prognosis and has limited treatment options. Currently, there are no therapies approved specifically to target *MET*-amplified tumors. Temab-A is an antibody-drug conjugate targeting c-Met and conjugated to a topoisomerase 1 inhibitor payload. In a first-in-human study (NCT05029882), Temab-A demonstrated encouraging activity (objective response rate 46%) and a manageable safety profile in *MET*-amplified solid tumors (Murciano-Goroff et al. ESMO 2025), supporting the continued investigation of Temab-A. The present phase 2 study evaluates Temab-A in adults and adolescents (12–17 years) with relapsed/refractory advanced solid tumors harboring *MET* amplification. **Methods:** This is an open-label, single-arm, global, multicenter phase 2 study (NCT07196644) enrolling approximately 125 patients (100 global; 25 China cohort) with locally advanced or metastatic solid tumors harboring *MET* amplification. Patients must have received ≥1 prior systemic therapy appropriate for their tumor type in the advanced/metastatic setting and have no satisfactory alternative treatment options. Patients must be ≥12 years old, have ECOG PS 0–1, measurable disease per RECIST v1.1 or RANO, and documented *MET* amplification by local next-generation sequencing or central FoundationOne CDx. Patients are treated with Temab-A 2.4 mg/kg IV every 3 weeks until disease progression, unacceptable toxicity, or other discontinuation criteria are met. Trial objectives are listed in the table. Enrollment began in November 2025; as of December 2025, 1 patient has enrolled. Clinical trial information: EU CT: 2024-518871-74-00. Research Sponsor: AbbVie.

Objectives.	
Primary	Evaluate efficacy (ORR per ICR, RECIST v1.1/RANO) and safety of Temab-A (AEs, vital signs, ECG, clinical laboratory testing)
Secondary	Further assess efficacy (DOR, PFS, OS, disease control) and characterize PK and immunogenicity (PK parameters, ADAs, nADAs)
Exploratory	Biomarker analyses (eg, c-Met expression) and PROs evaluation

ADAs, antidrug antibodies; AEs, adverse events; DOR, duration of response; ECG, electrocardiogram; ICR, independent central review; nADAs, neutralizing antidrug antibodies; ORR, objective response rate; OS, overall survival; PFS, progression-free survival; PK, pharmacokinetics; PROs, patient-reported outcomes; RANO, Response Assessment in Neuro-Oncology; RECIST v1.1, Response Evaluation Criteria in Solid Tumors version 1.1.

TPS3158 Poster Session

A phase I, multi-center study of KIVU-107, a novel PTK7-targeting antibody-drug conjugate (ADC), in participants with advanced solid tumors. First Author: Jeffrey C. Goh, ICON Research, South Brisbane & Queensland University of Technology, Brisbane, QLD, Australia

Background: Protein tyrosine kinase 7 (PTK7) is a transmembrane pseudokinase involved in normal embryonic development and has been associated with tumor initiation, metastasis and therapeutic resistance in cancer. PTK7 is over-expressed in multiple solid tumors, including lung, head and neck, breast, ovarian and endometrial cancers. KIVU-107 is an antibody-drug conjugate (ADC) comprised of a PTK7-targeting antibody conjugated to the SYNtecan E linker-payload via the GlycoConnect/Hydraspace (GC/HS) site-specific conjugation technology with a drug-to-antibody ratio of 4.[1,2] The GC/HS platform abolishes Fcγ receptor-mediated effector activity and utilizes a highly polar spacer to reduce hydrophobicity and aggregation of the ADC, translating into improved safety and pharmacokinetic profiles.[1,2] KIVU-107 has demonstrated potent anti-tumor efficacy as a single agent and in combination across multiple preclinical tumor models, including regression in tumors refractory to chemotherapy or ADCs.[1,2] Moreover, KIVU-107 is highly stable and well tolerated in non-human primates.[1,2] **Methods:** This Phase 1, multi-center, open-label, dose-finding and dose-expansion study is designed to investigate safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD) and preliminary efficacy of KIVU-107 in patients with select advanced solid tumors. The Dose Finding stage will employ Backfill Bayesian Optimal Interval (BF-BOIN) design to establish the maximum tolerated dose (MTD) and recommended dose for expansion (RDE). Eligible participants for the Dose Finding stage include those with advanced solid tumors known to be enriched for PTK7 overexpression and that have exhausted available standard-of-care (SOC) treatments including non-small cell lung, small cell lung, head and neck squamous cell carcinoma, breast, endometrial, ovarian and others. The Dose Expansion stage will further explore the safety, tolerability and preliminary efficacy in disease-specific cohorts relapsed or refractory to SOC therapies. The primary endpoints include safety, tolerability, and determination of MTD and RDE for KIVU-107. Secondary and exploratory endpoints include PK, immunogenicity, preliminary clinical activity and biomarker assessments. Enrollment for Dose Finding has initiated. Clinical trial information: NCT07229313. 1) Trikha M. Striving for Kinder and Gentler ADCs: Spotlight on Solid Tumor Target and Preclinical Development of KIVU-107. Presented at: 16th World ADC San Diego; November 4, 2025; San Diego, CA. 2) Viller V, Zhang L, Jiang X, et al. Preclinical Efficacy and Safety of KIVU-107, a Novel PTK7-Targeting Antibody-Drug Conjugate (ADC). Poster presented at: 16th World ADC San Diego; November 5, 2025; San Diego, CA. Clinical trial information: NCT07229313. Research Sponsor: Kivu Bioscience.

TPS3159 Poster Session

A phase 1, first-in-human study of DS3610, a stimulator of interferon genes (STING) agonist antibody-drug conjugate (ADC), in patients with advanced/metastatic solid tumors. First Author: Shigehiro Koganemaru, National Cancer Center Hospital East, Kashiwa, Japan

Background: While immunotherapies have improved treatment for patients with advanced/metastatic solid tumors, there remains a need for novel therapies that can overcome resistance to existing therapies, enhance antitumor activity, and delay disease progression. Promoting the innate immune response through activation of the endoplasmic reticulum adaptor protein stimulator of interferon genes (STING) has been associated with antitumor activity. DS3610 is an antibody–drug conjugate (ADC) comprising an anti-epidermal growth factor receptor (EGFR) monoclonal antibody attached to an immunomodulatory payload that acts as an agonist of STING. EGFR is a transmembrane receptor tyrosine kinase that is overexpressed in a broad range of solid tumors. DS3610 is designed to deliver the STING agonist payload directly to the tumor microenvironment, activating immune cells such as antigen-presenting cells and T cells, and inducing immune targeting of cancer cells. The antibody component has novel Fc modifications designed to reduce the risk of class-specific adverse events, such as systemic cytokine release. **Methods:** DS3610-071 (NCT07159126) is a Phase 1, first-in-human, open-label, global, dose-escalation study of DS3610 (N≈70). Patients must be adults with advanced or metastatic solid tumors and be intolerant to standard-of-care therapies or have disease that has relapsed after or is refractory to such therapies. Eligible tumor types include non-small cell lung cancer, head and neck cancer, renal cell carcinoma, urothelial carcinoma, colorectal cancer, gastric cancer, pancreatic cancer, esophageal cancer, biliary tract cancer, and uterine cancer. Patients must have measurable disease per RECIST 1.1; an ECOG performance status of 0, 1, or 2; and be willing and able to provide a pretreatment or archival tumor tissue sample. Patients will receive DS3610 at escalating doses. The primary objectives are to assess the safety and tolerability of DS3610 and to determine the recommended dose(s) for expansion for further evaluation of DS3610. Safety endpoints include identifying dose-limiting toxicities and treatment-emergent adverse events. Secondary endpoints include the assessment of DS3610 immunogenicity, based on the prevalence and incidence of antidrug antibodies, and the evaluation of DS3610 pharmacokinetics. Exploratory endpoints include evaluating the efficacy of DS3610 and identifying biomarkers that may be associated with clinical benefit. Enrollment is ongoing. Clinical trial information: NCT07159126. Research Sponsor: Daiichi Sankyo.

TPS3160 **Poster Session**

BNT326-01: A Phase 1b/2 trial of BNT326/YL202 (HER3 ADC) as monotherapy and in combination with pumitamig (anti-PD-L1 × VEGF bsAb) in patients with advanced solid tumors. First Author: Siqing Fu, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: BNT326/YL202 is an investigational ADC composed of an anti-HER3 IgG1 monoclonal antibody conjugated to ~8 molecules of a novel topoisomerase I inhibitor payload via a tripeptide linker. HER3 is frequently overexpressed in various solid tumors, particularly in relapsed or refractory tumors, making it an attractive therapeutic target. Increasing evidence suggests that ADCs may enhance the efficacy of immunotherapeutic agents. It is hypothesized that combining BNT326 with immunotherapy including pumitamig, an investigational anti-PD-L1 x VEGF-A bispecific antibody, could lead to better patient outcomes than administering either drug alone. Targeting angiogenesis may facilitate ADC penetration, which in turn could stimulate tumor immunity and increase sensitivity to PD-L1 inhibition. Preclinical in vivo models testing the combination of pumitamig with BNT326 showed superior tumor growth inhibition compared to each treatment alone (Hamilton E, AACR 2025, #648). **Methods:** This global Phase 1b/2, open-label, adaptive two-part multicohort trial (NCT07070232) will evaluate safety, efficacy, optimal dose and pharmacokinetics of BNT326 in selected indications, both as monotherapy (Part 1) and in combination with pumitamig (Part 2) in patients (≥18y, ECOG PS 0 or 1) with histologically or cytologically confirmed solid tumors that are advanced and/or have relapsed/progressed after prior therapy. Both parts will start enrolling patients independently of each other. In Part 1, patients in Cohorts 1A-C will be randomized to one of two dose levels of BNT326 based on doses derived from the ongoing monotherapy trials (YL202-INT-101-01 [NCT05653752] and YL202-CN-201-01 [NCT06107686], whereas Cohorts 1D, 1E, and 1G receive dose level 2 of BNT326. 1A: cutaneous melanoma 2L+; 1B: NSCLC 2L+, negative for actionable oncogenic alterations; 1C: EGFRm NSCLC 2L+; 1D: rare melanoma; 1E: other advanced solid tumors; 1F: drug-drug interaction cohort, dose defined in randomization cohorts 1A - 1C; and 1G: cervical cancer 2L+. In Part 2, patients in Cohorts 2A and 2B will receive two dose levels of BNT326 in combination with pumitamig. Patients in Cohorts 2D and 2E will receive two dose levels of BNT326 with pumitamig and dose level 2 of BNT326 as monotherapy. Patients in Cohort 2F receive one combination dose level. 2A: cutaneous melanoma 2L+; 2B: HER2-negative breast cancer 2L+/1L; 2C (optional, not open): cutaneous melanoma 1L+; 2D: gastric/gastroesophageal junction cancer 2L+; 2E: colorectal cancer 2L+; and 2F: cervical cancer 2L+. Primary endpoints are safety, overall response rate, and pharmacokinetics for cohort 1F. Enrollment for all cohorts is ongoing globally. Clinical trial information: NCT07070232. Research Sponsor: BioNTech SE.

TPS3161 **Poster Session**

A phase 1, multicenter, open-label, dose-escalation and expansion study to evaluate the safety, tolerability, pharmacokinetics, and preliminary efficacy of SBO-154 in subjects with advanced solid tumors. First Author: Charlotte Rose Lemech, Scientia Clinical Research-Prince of Wales Clinical School, Randwick, NSW, Australia

Background: Mucin 1 (MUC1) is a transmembrane glycoprotein overexpressed in advanced epithelial malignancies, where it promotes tumor progression and correlates with poor clinical outcomes. The membrane-proximal SEA domain of MUC1 is exposed on tumor cells and undergoes rapid internalization, enabling targeted intracellular delivery of cytotoxic payloads. SBO-154 is a MUC1 SEA–directed antibody–drug conjugate (ADC) conjugated to the clinically validated cytotoxic payload monomethyl auristatin E (MMAE) via a protease-cleavable linker. Unlike the shed MUC1-VNTR that creates an antigen sink limiting efficacy of prior ADCs, the negligibly shed MUC1-SEA epitope enables more effective SBO-154 tumor targeting. Nonclinical studies of SBO-154 showed MUC1-dependent cytotoxicity, dose-dependent tumor inhibition in vivo, and a favorable safety for clinical evaluation. This first-in-human study is designed to evaluate the safety, tolerability, pharmacokinetics (PK), immunogenicity, and preliminary antitumor activity of SBO-154 in subjects with locally recurrent or metastatic solid tumors who have exhausted or are intolerant to available therapies. **Methods:** This phase 1, open-label, multicenter study comprises two parts: dose escalation (Part 1) and dose expansion (Part 2). Eligible adults (≥18 years) must have RECIST v1.1–measurable, locally recurrent or metastatic solid tumors (excluding sarcoma), documented progression after or intolerance to standard therapy, ECOG performance status 0–1, adequate organ function, and tumor tissue for immunohistochemistry (IHC) analysis. SBO-154 will be administered as an intravenous infusion on Day 1 of each 21-day treatment cycle (Q3W) over 30 minutes. Part 1 will use an mTPI-2 design with intra-patient dose escalation from 0.3 mg/kg to 2.5 mg/kg. Approximately 75 subjects will be enrolled in Part 1 (~50 in dose escalation and ~25 in backfill cohorts), and up to 102 subjects in Part 2. After determining the maximum tolerated dose (MTD) and the recommended dose for expansion (RDE), Part 2 will be initiated with a Simon's two-stage design. Planned expansion cohorts will include NSCLC, ER+ breast cancer, and ovarian cancer, with enrolment to be restricted to tumors with high MUC1-SEA expression. Treatment will continue until disease progression, unacceptable toxicity, or withdrawal from the study. Primary endpoints: include dose-limiting toxicities (DLTs), treatment-related serious adverse events, dose modifications, and clinical/laboratory safety findings. Secondary endpoints: include PK, immunogenicity and efficacy. Enrollment Status: The study initiated enrolment in August 2025. Cohorts 1 and 2 have been completed without any DLTs, and enrolment in Cohort 3 is ongoing as of December 2025. Clinical trial information: NCT07042100. Research Sponsor: None.

TPS3162 **Poster Session**

Phase 1/2 study of CLIO-8221, a HER2-targeted, dual-payload exatecan and ATR inhibitor antibody-drug conjugate (ADC) in patients with advanced HER2-expressing solid tumors. First Author: Timothy A. Yap, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: CLIO-8221 is a novel anti-HER2 ADC designed to overcome topoisomerase 1 inhibitor (Topo1i) resistance by incorporating both Topo1i (exatecan) and ataxia telangiectasia and rad3-related protein inhibitor (ATRi; berzosertib) payloads. Enabled by proprietary dual-payload ADC linker technology, CLIO-8221 uses an Fc-engineered trastuzumab, site-specifically conjugated with a stable protease-cleavable linker designed for optimal efficacy and tolerability. Trastuzumab deruxtecan (T-DXd) has redefined the treatment paradigm for HER2-expressing breast cancer and is emerging as a frontline treatment option. However, most patients develop resistance and disease progression. Topo1i-induced replication stress triggers activation of the DNA damage response pathway, which is an important driver of Topo1i resistance. Studies show that ATRi synergizes with Topo1i to enhance DNA damage and increase antitumor activity. In preclinical studies, CLIO-8221 binds with high affinity and specificity to HER2-expressing tumor cells and is rapidly internalized to release the Topo1i and ATRi payloads to drive direct tumor cell killing with a strong bystander effect. CLIO-8221 shows superior *in vivo* efficacy across tumor models with a range of T-DXd sensitivity, inducing tumor regression after a single dose in T-DXd resistant and refractory xenograft models. Additionally, CLIO-8221 is designed to minimize off-target uptake through Fc engineering for abrogated FcγR binding, and a proprietary hydrophilic linker for reduced macropinocytosis. CLIO-8221 is well tolerated in nonclinical toxicity studies in non-human primates. **Methods:** CLIO-8221-001 is a Phase 1/2, first in human dose-escalation and -expansion study. Eligible patients are adults with metastatic or unresectable HER2-expressing solid tumors, including those who previously received T-DXd. Patients must have measurable disease per RECISTv1.1 and have previously received therapies known to confer clinical benefit unless ineligible, refused by the patient, or not available in the region. CLIO-8221 will initially be given by intravenous infusion on Day 1 of a 21-day cycle; treatment may continue until disease progression, unacceptable toxicity, or other reason for discontinuation. The primary objectives are to assess the safety and tolerability of CLIO-8221 and to identify the maximum tolerated dose, if reached, and recommended Phase 2 dose. Phase 1 of the study utilizes a BOIN dose-escalation design with an expansion phase, while Phase 2 comprises tumor-specific expansion cohorts treated at the doses recommended from Phase 1. Antitumor activity, PK, immunogenicity, and biomarkers including HER2 status and ctDNA dynamics will also be evaluated. Enrollment is planned at sites in Australia, US, and China (NCT07300943). Clinical trial information: NCT07300943. Research Sponsor: Callio Therapeutics.

TPS3163 **Poster Session**

Phase 1, first-in-human, open-label study evaluating the safety, tolerability, pharmacokinetics, and preliminary efficacy of TGW101 in patients with advanced solid tumors. First Author: Anthony W. Tolcher, NEXT Oncology San Antonio, San Antonio, TX

Background: Tumor-associated glycoprotein 72 (TAG-72) is a non-internalizing glycoepitope that is aberrantly expressed in a broad range of epithelial cancers, predominantly adenocarcinomas. TGW101 is an antibody-drug conjugate (ADC) therapy that utilizes a novel, bio-orthogonal click chemistry-based linker technology that enables the targeting of non-internalizing cancer antigens and controlled payload release. The first component of TGW101 is a chemically cleavable ADC (TGW101-ADC) that consists of a diabody targeting TAG-72 and a highly stable *trans*-cyclooctene (TCO) linker conjugated to a monomethyl auristatin E (MMAE) payload. Once the TGW101-ADC binds to intratumoral TAG-72 and is largely cleared from the systemic circulation, the second drug component, a tetrazine trigger (TRG001), is administered, leading to rapid MMAE release from TGW101-ADC via a selective cleavage reaction with the TCO linker. Upon release of MMAE into the tumor microenvironment, it readily diffuses into surrounding tumor cells, binds to microtubules, inhibits cell cycle progression, and activates local immune cells. In preclinical studies, TGW101 treatment led to tumor regressions in the OVCAR3 (ovarian) cell line and GXF214 (gastric) patient-derived xenograft model, and improved survival in LS174T (colon) tumor bearing mice. **Methods:** This first-in-human, open-label Phase 1 study evaluates the safety and tolerability of TGW101 and defines a maximum tolerated dose (MTD). A Bayesian Optimal Interval (BOIN) design is used to determine the recommended dosing regimen(s) for expansion. Secondary objectives include assessing the pharmacokinetic (PK) profile, intratumoral pharmacodynamics, preliminary anti-tumor activity, and immunogenicity of TGW101. Exploratory analysis will investigate the relationship between TAG-72 expression and tumor response, as well as the effect of TGW101 exposure on tumor biomarkers. Up to 50 participants with advanced solid tumors, including breast, NSCLC, prostate, cervical, endometrial, ovarian, gastroesophageal, and non-squamous cell carcinoma of the head and neck are planned for enrollment. During dose escalation, increasing doses of TGW101-ADC, administered intravenously on Day 1 followed 7 days later by a fixed-dose infusion of TRG001, will be explored in cohorts of 3-4 participants treated in 3-week cycles. Once pharmacologically active dose levels are identified, specific cohorts may enroll additional participants to further explore safety, PK, tumor biomarker changes, and efficacy. Adverse events are assessed according to CTCAE v5 and tumor response is determined by RECIST 1.1 or PCWG3 criteria every 6 weeks for the first 2 cycles, then every 9 weeks. The trial began in May 2025 and 7 sites, all within the United States, are open for enrollment. Clinical trial information: NCT06959706. Research Sponsor: None.

TPS3164 **Poster Session**

First-in-human clinical evaluation of ST-01156, an optimized and selective degrader of RNA-binding motif 39 (RBM39): A phase 1 study in advanced solid malignancies with a focus on RBM39-dependent cancers. First Author: Eric Keith Rowinsky, SEED Therapeutics Inc., King of Prussia, PA, China

Background: ST-01156 is an orally administered agent developed to degrade RBM39, a protein target that is principally involved with splicing RNA into messenger RNA and is commonly upregulated in cancer. ST-01156 has entered phase 1 clinical trials for the treatment of several cancer types supported by its novel mechanism of action and data from preclinical testing. The lead optimization process for ST-01156 maximized degradation selectivity, anticancer potency, metabolic stability (including deuteration), and other drug-like properties. The ability of ST-01156 to achieve functionally meaningful and selective effects is exemplified by complete degradation of RBM39 within hours following treatment *in vitro,* accompanied by downstream mis-splicing of pathogenic transcripts, most notably the *EWSR1-FLI1* fusion transcript driving Ewing sarcoma (ES). Adding to this effect, ST-01156 depleted proteins involved in DNA damage repair (DDR), supporting the potential for synthetic lethality with cancer cells that depend on proficient DDR. RBM39 is also involved in the splicing of KRAS isoforms thought to be essential for the proliferation and survival of oncogenic KRAS cancer stem cells, providing an anticancer mechanism distinct from the mechanisms of current KRAS inhibitory agents. In advanced hepatocellular carcinoma (aHCC), RBM39 is substantially overexpressed and likely impedes essential arginine sensor activities. In addition to demonstrating robust activity in these malignancies, ST-01156 is highly active in patient-derived xenograft models of neuroblastoma, biliary tract carcinoma (BTC), and endometrial carcinoma (EC). In animal toxicology studies, hematologic and gastrointestinal tissues were most susceptible to RBM39 inhibition. **Methods:** In the first-in-human study, ST-01156 doses will be adaptively escalated based on the rate and severity of adverse events in trial participants with advanced solid malignancies. ST-01156 will be administered orally for 5 consecutive days every 7 days with an option of adapting a continuous dosing schedule, if tolerable. Backfilling of safe dose levels with participants with high priority malignancies will be allowed. In addition to traditional safety and tolerability endpoints, dose escalation and Phase 2 dose derivation will be based on pharmacokinetic (PK) endpoints and real-time RBM39 targeting measurements in peripheral mononuclear cells. The optimal dose of ST-01156 derived from safety tolerability, PK and pharmacodynamic data will be evaluated in trial participants in the following expansion cohorts: A, ES; B, aHCC; C, *KRAS*-mutant cancers; and D, an adaptive cohort of cancers projected to be susceptible to RBM39 inhibition including BTC, EC, and cancers with DDR aberrations. Clinical trial information: NCT07197554. Research Sponsor: SEED Therapeutics Inc.

TPS3165 **Poster Session**

A phase 1/2 first-in-human study of TH9619 in patients with advanced refractory solid tumors (ODIN). First Author: Victor Moreno, START-Madrid-FJD Early Phase Clinical Trials Unit, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

Background: TH9619 is a first-in-class, potent, small-molecule, and dual inhibitor of methylene-tetrahydrofolate dehydrogenase (MTHFD)1 and MTHFD2, both highly overexpressed in solid tumors and cancer-specific key enzymes within the one-carbon metabolic pathway. TH9619 kills cancer cells via a dual mechanism of action (1) inhibition of MTHFD1 traps folate leading to thymidine depletion, and (2) inhibition of nuclear MTHFD2 disrupts DNA damage response and repair pathways. With its unique characteristics, in preclinical models, TH9619 kills tumour cells, while sparing healthy tissues. The results from pre-clinical models, the novel mechanism of action, and the high unmet medical need in advanced refractory solid tumours support this investigation. **Methods:** ODIN (NCT07151040; EudraCT No. 2024-519639-40-00) is a first-in-human, multicentre, open-label, Phase 1/2 study. Eligible patients include adults with histologically confirmed advanced colorectal cancer, non–small cell lung cancer, head and neck squamous cell carcinoma, gastric cancer, or gastroesophageal junction cancer who have exhausted the institutional standard of care and have progressive and measurable disease per RECIST 1.1. Patients will receive TH9619 monotherapy via an intravenous infusion, weekly for 3 weeks, followed by one week without infusion, of a 28-day cycle, for up to 2 years. The Phase 1a dose-escalation, planning to recruit up to 80 patients, will assess the overall safety and tolerability profile and determine the maximum tolerated dose (MTD) and recommended Phase 2 dose(s) (RP2D(s)). Phase 1b is cohort expansion and plans to recruit up to 60 patients. Assessments include adverse events, pharmacokinetic (PK) and pharmacodynamic (PD) parameters, and preliminary anti-tumor activity per RECIST v1.1. Additionally, predictive biomarkers and metabolites related to the one-carbon metabolism and potential correlation with efficacy of TH9619 will be explored. The Phase 2 will further characterize safety, PK, PD, and efficacy at the RP2D(s). The ODIN phase 1/2 study is actively enrolling across leading academic and clinical research centres in the United Kingdom, France, and Spain, with expansion planned across additional European sites in the coming months. As of this submission, dose escalation is ongoing. Clinical trial information: NCT07151040. Research Sponsor: None.

TPS3166 **Poster Session**

TAGNOT: A phase 1b/2 tumor-agnostic study of the selective anti-FGFR1 monoclonal antibody OM-RCA-01 in FGFR1-expressing advanced solid tumors. First Author: Igor A. Utyashev, Institute of Oncology, Hadassah Medical Moscow, Moscow, Russian Federation

Background: Fibroblast growth factor receptor 1 (FGFR1) plays a key role in the pathogenesis of multiple malignancies; however, no highly selective FGFR1-targeted therapies for solid tumors are currently approved. OM-RCA-01 is a humanized monoclonal antibody that selectively binds extracellular domains II–IIIc of FGFR1 with high affinity (Kd = 1.59 nM) and has demonstrated promising antitumor activity in preclinical models. In the first-in-human, tumor-agnostic (TAGNOT) study, patients with FGFR1-expressing advanced cancers are being treated with OM-RCA-01. **Methods:** TAGNOT is a phase 1b/2, multicenter, multicohort, prospective study designed according to the FDA-recommended OPTIMUS approach. Key eligibility criteria include FGFR1 expression by immunohistochemistry (IHC 2+ or 3+ in $\geq$10% of tumor cells) and metastatic disease progressing after $\geq$2 prior systemic treatment lines. The primary objective of the phase 1b component is to determine the recommended phase 2 dose (RP2D). Two dose levels of OM-RCA-01 (50 mg and 100 mg administered intravenously every 2 weeks) will be compared for safety (CTCAE v5.0), preliminary efficacy (objective response rate [ORR] per RECIST v1.1), pharmacokinetics, neutralizing antibody formation, and circulating tumor DNA dynamics. The primary endpoint of the phase 2 component is ORR in the ITT population. Five tumor-specific cohorts are planned: clear-cell renal cell carcinoma (n = 11), castration-resistant prostate cancer (n = 11), non-small cell lung cancer without EGFR or ALK alterations (n = 11), breast adenocarcinoma with known receptor status (n = 11), and head and neck squamous cell or salivary gland carcinomas (n = 11). Using Simon's two-stage design, a total of 55 patients will be enrolled. The null hypothesis of a true ORR of 10% will be tested against a one-sided alternative of 25%. The study will be terminated after the first stage if $\leq$3 responses are observed among 31 patients. Otherwise, 24 additional patients will be enrolled. The null hypothesis will be rejected if $\geq$10 responses are observed in 55 patients, yielding a one-sided type I error rate of 0.05 and 90% power. Clinical trial information: NCT07292168. Research Sponsor: Bureau for Cancer Research - BUCARE.

TPS3167 **Poster Session**

A first-in-human study of ATX-295, an oral inhibitor of KIF18A, in patients with advanced or metastatic solid tumors, including ovarian cancer. First Author: Judy S. Wang, Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, FL

Background: ATX-295 is an oral inhibitor of KIF18A, an adenosine triphosphate (ATP)-dependent, plus end-directed mitotic kinesin. KIF18A facilitates chromosomal alignment and spindle microtubule dynamics during mitosis in certain advanced solid tumors with chromosomal instability (CIN). In preclinical studies, ATX-295 demonstrated robust antiproliferative activity in chromosomally instable solid tumor models, including in high grade serous ovarian cancer. In vivo, oral administration of ATX-295 induced dose-dependent tumor growth inhibition in CIN platinum-resistant ovarian and squamous non-small cell lung cancer cell-line derived xenograft (CDX) and patient derived xenograft (PDX) models. **Methods:** NCT06799065 is a multi-center, first-in-human, Phase 1/2, open-label, single-arm, dose-escalation and expansion study to evaluate the safety profile of ATX-295 and determine the recommended phase 2 dose (RP2D) in subjects with locally advanced or metastatic solid tumors. The study in progress will be conducted in two parts: dose escalation, followed by dose expansion. Participant enrollment and continuous safety assessment will be guided by a mTPI-2 design (Guo, 2017) to identify an optimal dose. To assess evidence of preliminary antitumor activity, a Simon 2-stage design (Simon, 1989) will be used during dose expansion. Key eligibility criteria: patients with histologically confirmed solid tumors who have locally recurrent or metastatic disease, including high grade serous ovarian cancer (HGSOC) and squamous non-small cell lung cancer (sqNSCLC); refractory to or relapsed after all standard therapies with proven clinical benefit. For the expansion cohorts, participants must have histological confirmation of HGSOC and be determined to be platinum-resistant, platinum-refractory, or platinum-intolerant; have measurable disease; have an Eastern Cooperative Oncology Group (ECOG) performance status of 0 to 1. Primary endpoints will evaluate safety and tolerability of ATX-295 at pharmacologically active dose(s) and/or schedule(s) and determine the recommended phase 2 dose (RP2D). Secondary endpoints will evaluate pharmacokinetics (PK) of ATX-295 in plasma and evaluate pharmacodynamic (PD) effects of ATX-295 to assess preliminary evidence of anti-tumor activity. The study is actively recruiting. Clinical trial information: NCT06799065. Research Sponsor: Accent Therapeutics.

TPS3168 **Poster Session**

First-in-human phase 1 dose escalation and expansion study of PIN-5018, a CK1α-selective molecular glue degrader, in patients with advanced solid tumors. First Author: Bhumsuk Keam, Department of Internal Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, South Korea

Background: Casein kinase 1 alpha (CK1α) is a serine/threonine kinase involved in multiple oncogenic signaling pathways regulating cell proliferation, differentiation, and survival. Dysregulation of CK1α has been implicated across several solid tumor types, supporting its evaluation as a therapeutic target. PIN-5018 is an orally administered, CK1α-selective molecular glue degrader designed to induce targeted proteasomal degradation of CK1α via cereblon-mediated ubiquitination. Previously presented preclinical studies have demonstrated selective CK1α degradation and antitumor activity in multiple solid tumor models, providing the scientific rationale for first-in-human clinical evaluation. In addition to safety and dose optimization, the study incorporates tumor- and blood-based correlative analyses to characterize CK1α degradation and downstream pathway modulation. **Methods:** PIN-5018-001 is an ongoing, first-in-human, open-label, multicenter phase 1 study evaluating PIN-5018 in patients with progressive, locally advanced (unresectable), or metastatic solid tumors who have exhausted standard treatment options. The study consists of a dose escalation phase followed by dose expansion at selected dose levels based on safety, pharmacokinetics, and preliminary antitumor activity. PIN-5018 is administered orally once daily in 21-day cycles (14 days on treatment followed by 7 days off). Dose escalation evaluates six planned dose levels (10–100 mg) using a Bayesian Optimal Interval (BOIN) design with a target dose-limiting toxicity rate of 25%. Dose-limiting toxicities are assessed during Cycle 1. Up to 36 patients may be enrolled in dose escalation, with plan to add dose optimization and dose expansion cohorts. Eligible patients are adults (≥18 years) with ECOG performance status 0–1 and at least one measurable lesion per RECIST v1.1. Mandatory pre-treatment and on-treatment tumor biopsies are required when medically feasible to support correlative biomarker analyses. Enrollment has begun. Cohort 1 has been completed without DLT, and enrollment to subsequent cohorts is ongoing. Clinical trial information: KCT0011322. Research Sponsor: Pin Therapeutics, Inc.

TPS3169 **Poster Session**

An open-label, multicenter study of DPTX3186 to evaluate safety, tolerability, and pharmacokinetics in subjects with known Wnt pathway–activated solid tumors where no other treatments exist. First Author: Alexander I. Spira, Virginia Cancer Specialists and NEXT Oncology, Fairfax, VA

Background: Constitutive activation of the Wnt/β-catenin pathway drives malignancy in a wide range of cancers, where β-catenin has been notoriously difficult to drug due to its disordered nature, lack of defined drug-binding pockets, and associated toxicities. Biomolecular condensates are membraneless organelles that orchestrate cellular processes, biological pathways, and protein activity by compartmentalizing biomolecules. DPTX-3186 is a small molecule condensate modulator (c-mod) that acts via a novel mechanism of action, sequestering β-catenin into inactive condensate depots. This sequestration selectively inhibits β-catenin-driven transcription and induces robust cancer cell death. DPTX3186 is an orally bioavailable small molecule c-mod that demonstrates strong anti-tumor activity across multiple tumor types driven by various defects along the Wnt/β-catenin pathway. Studies in xenographs show that DPTX-3186 modulates Wnt pathway activity as evidenced by formation of inactive β-catenin condensates and modulation of β-catenin-driven gene transcription. Profound pharmacological efficacy, including regressions and complete responses, has been observed in murine models of gastric cancer as monotherapy. The molecule has been granted Fast Track and Orphan Drug Designations by the FDA. **Methods:** This first-in-human, phase 1/2, multicenter, open-label, dose-escalation (phase 1) and dose-expansion (phase 2) study evaluates the safety/tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and anti-tumor effects of DPTX3186 monotherapy in patients with known Wnt pathway activated solid tumors. Eligible patients must have no other approved treatment options available. In Phase 1, DPTX3186 is administered orally in a 4 days on / three days off schedule, at escalating dose levels, evaluated sequentially in a BOIN design. Phase 2 dose expansion will utilize a TOP-BOIN design and will evaluate DPTX3186 monotherapy in patients with histologically or cytologically confirmed non-resectable gastric adenocarcinoma who are refractory to prior treatment. Primary endpoints are safety and tolerability of DPTX-3186, including dose-limiting toxicities (DLT) and the determination of the MTD and recommended dose for expansion. Secondary endpoints are PK, PD, and preliminary anti-tumor activity (e.g. overall response rate, duration of response, progression-free survival, disease control rate, and overall survival). 40 patients are planned to be enrolled in Part 1, which is currently enrolling in the USA. Clinical trial information: NCT07312903. Research Sponsor: Dewpoint Therapeutics.

TPS3170 **Poster Session**

Phase 1/2 study of the novel Werner helicase inhibitor EIK1005 as monotherapy and in combination with pembrolizumab in patients with advanced solid tumors, including MSI-H or dMMR tumors. First Author: Timothy A. Yap, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Cancers with deficient mismatch repair (dMMR) have high microsatellite instability (MSI-H) and are reported to be sensitive to inhibition of the Werner syndrome helicase (WRN) via synthetic lethality. WRN inhibition in MSI-H cells leads to loss of genomic integrity and ultimately cell death while not affecting microsatellite stable (MSS) and healthy cells. Standard of care for patients (pts) with MSI-H tumors includes surgery and immunotherapy (checkpoint inhibitors [CPIs] like pembrolizumab [pembro]). While these are viable treatment options, depending on the indication, ~30 to 50% do not respond to first-line immune CPIs, or acquire resistance. A critical unmet medical need exists for new therapies for such patients (pts). EIK1005 is a novel, potent, high-affinity and selective WRN inhibitor (WRNi) with the potential for targeted antitumor activity in MSI-H or dMMR solid tumors. In vitro studies demonstrated sustained target engagement leading to cell death in MSI-H cells while sparing MSS and healthy cells. In a Phase 1 single ascending dose study in healthy participants, EIK1005 was well tolerated at the doses evaluated. **Methods:** EIK1005-002 (NCT#07262619) is a multicenter, multi-part, Phase 1/2 study of EIK1005 monotherapy and combination with pembro, in participants with advanced solid tumors including MSI-H and dMMR tumors. The study has three parts; Part 1A (monotherapy dose escalation [DE]): EIK1005 will be evaluated at ~ three dose levels (DL) in participants without alternative therapeutic options (n~40). Preference is given to pts with MSI-H or dMMR cancer for whom prior CPI therapy has failed, or with MSS cancer who progressed after ≥1 regimen of platinum, alkylating or topoisomerase chemotherapy as evidence suggests MMR alterations and MSI induction in previously MSS cancer. Part 1B (combination DE): participants with MSI-H or dMMR tumors (n~40) will receive EIK1005 + pembro (Q3W). Part 2 (dose optimization [DO]): participants (n~80) with MSI-H and dMMR tumors and slowly progressive disease are randomized 1:1 to receive EIK1005 at one of two doses from Part 1A. Key eligibility criteria: participants ≥18 years, life expectancy ≥3 months, unresectable and/or metastatic solid tumor, measurable disease at baseline (RECIST v1.1), progression after or intolerance to ≥ 1 advanced-setting standard treatment regimen (Part 1A), has MSI-H or dMMR tumor (Parts 1B and 2) and slowly progressive disease (Part 2). Primary objectives: safety and tolerability of EIK1005 monotherapy and + pembro to determine the MTD (Part 1) and to inform DO (Part 2). Secondary objectives: preliminary antitumor activity, characterize plasma PK profile of EIK1005 monotherapy and + pembro. This study began in December 2025. Clinical trial information: NCT07262619. Research Sponsor: None.

TPS3171 **Poster Session**

Phase 1, multi-center clinical trial evaluating the safety, pharmacokinetics, pharmacodynamics and anti-cancer activity of PQ203, a first-in-class peptide drug conjugate targeting SORT1 in patients with advanced solid tumor malignancies (NCT07190469). First Author: Philippe Bedard, Princess Margaret Cancer Centre – University Health Network, University of Toronto, Toronto, ON, Canada

Background: Antibody–drug conjugates (ADCs) have improved outcomes in several refractory cancers by enabling the targeted delivery of potent cytotoxins but their use is limited by suboptimal payload release, off-target and immune-related toxicities, poor tumor penetration and complex manufacturing. Peptide drug conjugates (PDCs) offer potential advantages over ADCs including smaller size, increased tumor penetration, more rapid systemic clearance and decreased immunogenicity. PQ203 is a first in class, AI-designed PDC comprised of a 17 amino acid peptide targeting sortilin (SORT1) conjugated to the cytotoxin monomethyl auristatin E (MMAE) via a para-amino-benzyl-valine-citrulline (PAB-VC) cleavable linker. SORT1, a receptor of the Vps10p family involved in protein trafficking, is overexpressed across multiple tumor types and associated with tumor invasiveness. Preclinical breast cancer models, including patient-derived xenografts, show that PQ203 can overcome resistance to commonly used TOP1-based ADCs. **Methods:** This first-in-human, multi-country Phase 1A/B dose-escalation, expansion and optimization clinical trial is designed to assess the safety, pharmacokinetics, pharmacodynamics, immunogenicity and preliminary anti-tumor activity of PQ203. Treatment consists of once weekly IV infusion × 4 weeks (Q1Wx4) and continues until the occurrence of disease progression or dose-limiting toxicity. In Part 1 of the study, up to 7 dose cohorts are anticipated (commencing at 0.02 mg/kg) in a backfill Bayesian optimization (BF-BOIN) dose escalation design with a target toxicity rate of 27.5%. Upon satisfaction of pre-defined safety criteria for particular dosing cohorts, up to 9 additional patients (pts.) in pre-defined settings of biologic and clinical interest may be enrolled to backfill expansion of that dose level. Upon identification of one or more recommended doses for expansion, up to 50 pts. across 1-3 tumor types of particular clinical interest, including pts. with triple negative breast cancer, will be enrolled in the expansion and dose optimization phases of the study. Alternative dosing schedule(s) with reduced frequency may additionally be explored based on emerging PK and safety data. At the time of submission, cohorts 1 and 2 were completed without DLTs and enrollment of Cohort 3 was initiated in January, 2026. Clinical trial information: NCT07190469. Research Sponsor: None.

TPS3172 **Poster Session**

A phase 1 first-in-human study of BGM-2121 in patients with advanced solid tumors. First Author: Chien-Chih Ou, BioGate Precision Medicine Corporation, Taipei, Taiwan

Background: Parathyroid hormone-related protein (PTHrP) is a hormone frequently overexpressed in tumors such as pancreatic ductal adenocarcinoma (PDAC), lung, and head and neck cancers. In some cases, this overexpression can lead to hypercalcemia in patients with malignancies. PTHrP is a ligand of G-protein–coupled receptor (GPCR) known as parathyroid hormone type 1 receptor (PTH1R), thereby activating multiple downstream signaling pathways. Despite the significant role of GPCRs in cancer biology, therapeutic options targeting these receptors in oncology remain limited. BGM-2121 is a potent, first-in-class, humanized IgG1 monoclonal antibody targeting the N-terminal region of PTHrP, aiming to inhibit the PTHrP/PTH1R pathway. Preclinical studies exhibit high affinity and specificity for PTHrP, demonstrating robust antitumor activity in pancreatic cancer xenograft models, and significantly prolonging survival. In lung squamous cell carcinoma models, BGM-2121 was found to prevent and reverse hypercalcemia and cancer-associated weight loss, which are the key features of humoral hypercalcemia of malignancy and cachexia. **Methods:** BGM-2121-001 (NCT07346846) is a first-in-human, open-label, phase 1 trial designed to evaluate the safety, tolerability, pharmacokinetics, and preliminary antitumor, anti-cachexia, and anti-hypercalcemia activity in adults with advanced solid tumors. Eligible participants are adults with histologically or radiographically confirmed advanced solid tumors who are refractory to, intolerant of, or without available standard therapies. Tumor types of primary interest include pancreatic, esophageal, head and neck, and non–small cell lung cancers, particularly sub-type of squamous cell carcinoma. Participants must have ECOG performance status $\leq$2 and adequate organ function. Key exclusions include active central nervous system metastases, significant cardiovascular disease, uncontrolled infections, recent anticancer therapy, prior allogeneic transplantation, active viral hepatitis or HIV infection. BGM-2121 is administered intravenously every 2 weeks in sequential dose-escalation cohorts (160, 320, 480, 800, and 1200 mg) using a standard 3+3 design. Dose-limiting toxicities are assessed during the first 28 days, and the maximum tolerated dose is defined as the highest dose at which $\leq$1 of 6 patients experiences a dose-limiting toxicity. Dose modifications are determined by the Safety Review Committee. Treatment continues until disease progression, unacceptable toxicity, or loss of clinical benefit. Clinical trial information: NCT07346846. Research Sponsor: Biogate Precision Medicine Corporation.

TPS3173 **Poster Session**

A multicenter phase 1/1b study of AMG 436 as monotherapy and combination therapy in patients with advanced MSI-H/dMMR solid tumors. First Author: Elizabeth Won, Amgen Inc., Thousand Oaks, CA

Background: Microsatellite instability-high (MSI-H)/mismatch repair deficiency (dMMR) tumors are characterized by high mutational burden and replication stress. These tumors rely on Werner syndrome protein (WRN), a DNA helicase required for DNA replication and repair, to sustain tumor cell survival. As a result, this reliance on WRN creates a synthetic lethal vulnerability, making WRN inhibition a promising therapeutic strategy. AMG 436 is a selective, covalent WRN inhibitor that is designed to exploit this dependency in MSI-H/dMMR tumors. AMG 436 represents a tumor-intrinsic approach that is mechanistically distinct from immune checkpoint inhibitors (ICIs), the current standard of care. This first-in-human Phase 1/1b trial evaluates AMG 436 as monotherapy and in combination with immune checkpoint inhibitors and/or chemotherapy in adults with MSI-H/dMMR solid tumors, including ICI-naïve and post-ICI populations. **Methods:** This study is a Phase 1/1b, open-label, multicenter trial enrolling approximately 464 adult participants with metastatic or locally advanced MSI-H/dMMR solid tumors. The study consists of 4 parts: Part 1 involves monotherapy dose exploration; Part 2 explores combination doses with chemotherapy or an immune checkpoint inhibitor; Part 3 focuses on monotherapy dose expansion and randomized dose optimization; and Part 4 involves combination dose expansion with chemotherapy and/or ICIs. The primary objectives are to assess safety and determine the maximum tolerated dose or recommended dose for expansion, with primary endpoints being the incidence of dose-limiting toxicities (DLTs) during the DLT evaluation period and the incidence of treatment-emergent adverse events and serious adverse events. Secondary objectives include pharmacokinetics and preliminary antitumor activity per RECIST v1.1. Descriptive statistics will be used to summarize safety, pharmacokinetic, and efficacy data. Key eligibility criteria are adults with MSI-H/dMMR status, ECOG 0–1, and adequate organ function. Enrollment is ongoing globally across North America, South America, Europe, and Asia-Pacific. Participants may remain on treatment for up to 2 years, with total trial duration including follow-up extending up to 5 years. Clinical trial information: 177459. Research Sponsor: Amgen Inc.

TPS3174 **Poster Session**

Phase I study of [^{225}Ac]Ac-ETN029, a DLL3-targeted radioligand therapy, in patients with advanced DLL3-expressing solid tumors. First Author: Cristiano Ferrario, Jewish General Hospital, McGill University, Montreal, QC, Canada

Background: Delta-like ligand 3 (DLL3) is an atypical Notch ligand that is highly expressed in small cell lung cancer (SCLC) and other neuroendocrine carcinomas, with minimal expression in normal adult tissues. [^{225}Ac]Ac-ETN029 (^{225}Ac-ETN029) is a novel, DLL3-targeted, macrocyclic peptide-based radioligand therapy (RLT) demonstrating potent antitumor activity in DLL3-positive, SCLC cell line–derived, xenograft mouse models. Here, we describe CESP359A12101 (NCT07006727), a global first-in-human phase 1 study evaluating ^{225}Ac-ETN029 in patients with selected advanced DLL3-expressing solid tumors. **Methods:** The primary objectives of the study are to assess the safety and tolerability of ^{225}Ac-ETN029 and to identify the recommended radioactive dose(s) of ^{225}Ac-ETN029 for further clinical evaluation. Secondary objectives are to assess the preliminary antitumor activity of ^{225}Ac-ETN029, characterize the pharmacokinetics (PK) and dosimetry of ^{225}Ac-ETN029, and characterize the safety, PK, dosimetry, and imaging properties of [^{111}In]In-ETN029 (^{111}In-ETN029). Study participants are expected to receive 4 cycles of ^{225}Ac-ETN029 at 6-week intervals, although a lower or higher number of cycles may be explored if deemed beneficial and safe. The study includes dose escalation and dose expansion parts. During dose escalation, increasing levels of administered activity per cycle will be assessed across cohorts. Dose escalation decisions will be based on a review of all available data, including safety, tolerability, dosimetry, PK, pharmacodynamics, and preliminary efficacy, and guided by the Bayesian logistic regression model using the escalation with overdose control principle. Dose expansion will begin once recommended radioactive dose(s) of ^{225}Ac-ETN029 for further clinical investigation have been determined. Eligible patients must be $\geq$18 years old; have locally advanced, unresectable, or metastatic disease measurable per RECIST v1.1; and be diagnosed with one of the following: (1) SCLC, (2) large cell neuroendocrine carcinoma (LCNEC) of the lung (escalation only), (3) de novo or castration-resistant, treatment-emergent, neuroendocrine prostate cancer (NEPC; expansion only), or (4) gastroenteropancreatic neuroendocrine carcinoma (GEP-NEC; expansion only). Patients with SCLC, LCNEC, and GEP-NEC must have disease progression following, or intolerance of, $\geq$1 prior line of systemic therapy. Patients with NEPC and GEP-NEC must have $\geq$1 measurable lesion (per RECIST 1.1) demonstrating ^{111}In-ETN029 uptake higher than surrounding tissues on SPECT/CT as assessed by the investigator. Patients with prior DLL3-targeted therapy (except for SCLC) or prior RLT (except for NEPC) will be excluded. Patient enrollment began in October 2025. Clinical trial information: NCT07006727. Research Sponsor: None.

TPS3175 **Poster Session**

Alpha-emitting radionuclide or beta-emitting radionuclide combined with metastasis-directed stereotactic body radiotherapy for oligorecurrent prostate adenocarcinoma (ANDROMEDA): A phase II trial. First Author: Kekoa Taparra, Department of Radiation Oncology, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA

Background: The recent LUNAR study (NCT05496959) found that adding beta-emitting ^{177}Lutetium-PNT2002 (^{177}Lu-PSMA) to stereotactic body radiation therapy (SBRT) more than doubled median progression-free survival (PFS) compared to SBRT alone in oligorecurrent hormone-sensitive prostate cancer (orHSPC), hazard ratio (HR)=0.37. However, the relative efficacy compared to novel alpha-emitting ^{225}Actinium-PSMA-617 (^{225}Ac-PSMA) is unknown. The hypothesis is that ^{225}Ac-PSMA will improve PFS by treating more micrometastases, given its higher radiobiologic effectiveness. We aim to compare the relative benefit of 2 cycles of ^{177}Lu-PSMA versus 1 cycle of ^{225}Ac-PSMA followed by SBRT metastasis-directed therapy (MDT). **Methods:** ANDROMEDA (NCT07150715) is a phase II, non-blinded, single-center randomized trial for individuals with orHSPC and 1-5 PSMA-avid metastases outside the prostate/prostate bed (N1 and/or M1). Eligibility criteria include testosterone $>$150 ng/dL, $\geq$18 years, and ECOG performance status $\leq$2. Exclusion criteria include *de novo* metastatic disease, castrate-resistance (testosterone $<$50 ng/mL with rising PSA), ADT/chemotherapy within 6 months of enrollment, and neuroendocrine histology. Participants are randomized 1:1 to 2 cycles ^{177}Lu-PSMA (7.4 GBq/cycle, 6 weeks apart) or 1 cycle of ^{225}Ac-PSMA (8 MBq, once), followed by SBRT to all lesions 1-2 weeks after radioligand therapy infusion. The primary endpoint of PFS is defined as the time from randomization to either 1) a new PSMA-avid lesion or 2) PSMA-PET local progression ($>$30% SUV increase or $>$20% increase in the sum of the longest lesion diameters) with a PSA rise. For those alive without progression, PFS will be censored at the time of the last scan. All randomized subjects will be analyzed based on intent-to-treat. Secondary endpoints include 24-month disease burden by PSMA-PET, physician-scored toxicity, patient-reported quality of life, ADT-free survival, local control of SBRT lesions at 24 months after last radionuclide infusion, and time-to-progression (locoregional, distant, new metastasis). We hypothesize that the 24-month post-SBRT PSA-based recurrence rate of ^{177}Lu-PSMA will be ~50%, which will be reduced with ^{225}Ac-PSMA to ~30% (PFS HR~0.51). We anticipate an accrual time of 1.5 years and a median follow-up time of 24-months. A sample size of 96 patients (48 per arm) would provide 80% power to detect the expected difference in PFS at a 0.1 alpha level. Assuming a 10% drop-out/screen failure rate, the target trial accrual is 107 patients. Early stopping guidelines include monitoring site-specific grade 4-5 toxicity with a safety threshold of 20% from the time of the first enrolled patient, which would trigger halting the trial and safety consultation. ANDROMEDA is currently open for enrollment. Clinical trial information: NCT07150715. Research Sponsor: None.

TPS3176 **Poster Session**

[^{212}Pb] Pb-MP0712 in patients with small cell lung cancer and other Delta-like ligand 3–expressing solid tumors: A phase 1/2a study to assess safety, tolerability, and efficacy. First Author: Ticiana Leal, Winship Cancer Institute of Emory University, Atlanta, GA

Background: [^{212}Pb]Pb-MP0712 is a novel radiopharmaceutical comprising a Designed Ankyrin Repeat Protein (DARPin) that binds with high affinity to DLL3 and carries the alpha-emitting isotope lead-212 (^{212}Pb) for targeted delivery of high linear energy transfer radiation. DLL3 is highly expressed in SCLC, large cell neuroendocrine carcinoma (LC-NEC) of the lung, and extrapulmonary NEC (epNEC), while its expression in healthy tissue is virtually absent. In preclinical studies, [^{212}Pb]Pb-MP0712 selectively accumulates in DLL3-positive tumors, exhibits an adequate biodistribution profile, and induces complete and durable tumor regression with prolonged survival and a favorable safety profile (Croset et al. AACR 2025). Initial human imaging data from a patient who received [^{203}Pb]Pb-MP0712 in a Named Patient Access Program under the legal framework for compassionate care in South Africa indicate its specific uptake in tumor (Steiner et al. TRP EU 2025). **Methods:** This first-in-human Phase 1/2a study evaluates the safety, biodistribution, dosimetry, and preliminary antitumor efficacy of [^{212}Pb]Pb-MP0712 (NCT07278479). Key inclusion criteria are SCLC and progression or recurrence following $\geq$2 prior lines of systemic therapy, or lung LC-NEC or epNEC with progression or recurrence following $\geq$1 prior line of systemic therapy, and measurable disease by RECIST v1.1. Patients with clinically stable central nervous system metastasis or prior DLL3-targeted therapy are eligible. Key exclusion criteria are Merkel cell carcinoma, neuroendocrine prostate cancer, interstitial lung disease, and active non-infectious pneumonitis. This study has two parts, a dose escalation (Part 1) and an expansion (Part 2). Primary objectives of Part 1 are to evaluate safety and tolerability of [^{212}Pb]Pb-MP0712, and to determine the maximum tolerated dose and recommended phase 2 dose (RP2D). Primary objective of Part 2 is to assess preliminary antitumor activity of [^{212}Pb]Pb-MP0712. All patients will receive a single dose of [^{203}Pb]Pb-MP0712 as intravenous (IV) injection at 185 MBq to evaluate DLL3-expressing tumor lesions, pharmacokinetics, biodistribution and dosimetry using single-photon emission computerized tomography (SPECT)/CT, followed by [^{212}Pb]Pb-MP0712 treatment. In study Part 1, for SCLC/lung LC-NEC cohorts, treatment proceeds regardless of imaging results; for epNEC cohorts, a DLL3-positive SPECT/CT is required. Patients will be enrolled in sequential cohorts to receive escalating doses of [^{212}Pb]Pb-MP0712 as IV injection on Day 1 of each 28-day cycle for up to six cycles. The dose escalation will be guided by an adaptive Bayesian Logistic Regression Model. Upon completion of Part 1, Part 2 will enroll two groups of patients with DLL3-positive SCLC/lung LC-NEC or epNEC at the RP2D. Clinical trial information: NCT07278479. Research Sponsor: Molecular Partners AG, Zuerich-Schlieren, Switzerland; Orano Med SAS.

TPS3177 **Poster Session**

Beamion BCGC-1: Four new phase Ib/II cohorts to evaluate oral zongertinib with other agents in HER2-positive metastatic breast cancer (mBC) and metastatic colorectal cancer (mCRC). First Author: Kohei Shitara, National Cancer Center Hospital East, Kashiwa, Japan

Background: Zongertinib, an oral, irreversible TKI, selectively inhibits HER2 while sparing wild-type EGFR, thereby minimizing associated toxicities. Beamion BCGC-1 (NCT06324357) is an ongoing Phase (Ph) Ib/II trial evaluating zongertinib in HER2-positive tumors. Trial details for Cohorts A–K, evaluating zongertinib as monotherapy or combined with T-DM1, T-DXd, or trastuzumab $\pm$ capecitabine in patients (pts) with HER2-positive mBC, and with T-DXd in pts with HER2-positive metastatic gastric, gastroesophageal junction, or esophageal adenocarcinoma (mGEAC), have recently been published (Hurvitz et al, *Future Oncol* 2025). In addition to BC and GEAC, early-phase data indicate zongertinib is also active in mCRC (Yoh et al, *Ann Oncol* 2025, abstr 491P). Here, we report 4 new cohorts (L–O) to evaluate the efficacy and safety of zongertinib plus zanidatamab in HER2-positive mBC, or plus trastuzumab or mFOLFOX6 $\pm$ trastuzumab in HER2-positive mCRC. **Methods:** For the 4 new cohorts, pts must have histologically/cytologically confirmed, unresectable HER2-positive mBC or mCRC, and documented HER2-positive disease (overexpression/amplification). Pts with mBC must have disease progression following $\geq$1 prior HER2-targeted treatment; pts with mCRC must have disease progression/recurrence during or following their latest treatment. Pts with brain metastases are allowed. There are 3 new Ph Ib cohorts (M, N, and O; each ~20 pts). Cohorts M and N will assess zongertinib in mCRC: pts will receive once-daily zongertinib across escalating dose levels plus mFOLFOX6 every 14 days (Cohort M), or mFOLFOX6 every 14 days + trastuzumab every 21 days (Cohort N; Table). In Cohort O, pts with mBC will receive once-daily zongertinib across escalating dose levels plus zanidatamab every 21 days. Dose escalation will be guided by a BLRM with overdose control. In Ph II, Cohort L, a new dose justification cohort (~40 pts with mCRC), will receive zongertinib 120 mg once daily plus trastuzumab every 21 days. In Ph Ib, the primary endpoint is DLTs during the MTD evaluation period; secondary endpoints include objective response (OR) by RECIST v1.1, DLTs in the on-treatment period, and pharmacokinetics (PK). In Ph II, the primary endpoint is OR by RECIST v1.1; secondary endpoints include PFS, disease control, AEs leading to dose reduction, PK, and pt-reported outcomes. Pts will remain on treatment until any protocol-defined stopping criterion occurs. Clinical trial information: NCT06324357. Research Sponsor: Boehringer Ingelheim.

Cohort	Indication	Zongertinib Regimen
Ph Ib dose escalation		
M	mCRC	+ mFOLFOX6: oxaliplatin (85 mg/m^2), leucovorin (400 mg/m^2), 5-FU (2400 mg/m^2)
N	mCRC	+ mFOLFOX6: oxaliplatin (85 mg/m^2), leucovorin (400 mg/m^2), 5-FU (2400 mg/m^2) + trastuzumab (8 mg/kg loading; 6 mg/kg maintenance)
O	mBC	+ zanidatamab (1800 mg $<$70 kg; 2400 mg $\geq$70 kg)
Ph II dose justification		
L	mCRC	+ trastuzumab (8 mg/kg loading; 6 mg/kg maintenance)

TPS3178 **Poster Session**

A study of MT-4561 in patients with various advanced solid tumors (NCT06943521). First Author: Kimberly Lynne Futch, Tanabe Pharma America, Inc., Jersey City, NJ

Background: MT-4561 is a bromodomain-containing protein 4 (BRD4) protein degrader, which is a bi-functional molecule having both a binder moiety that binds to BRD4 and a degron moiety that binds to damage-specific deoxyribonucleic acid (DNA) binding protein 1 (DDB1) and cullin 4 (CUL4) associated factor 16 (DCAF16), which is responsible for the ubiquitination of BRD4. MT-4561 degrades BRD4, a bromodomain protein that stimulates oncogene transcription, using the ubiquitin-proteasome system. Tanabe Pharma has demonstrated that this novel BRD4 degrader, MT-4561, exerts continuous anti-tumor effects in various cancer xenograft models (Ooike, 2024). **Methods:** This trial is a FIH, Phase I/II study to evaluate safety, tolerability, PK, PD, and efficacy of MT-4561 in patients with advanced solid tumors. Part 1 is evaluating safety, tolerability, PK, MTD, and the doses to be investigated in Part 2 (dose optimization) using the BOIN design. Part 2 evaluates the safety and efficacy of MT-4561 in patients with pre-specified tumor types based on data from Part 1, and to determine the RP2D. Part 2 can begin enrollment after the MTD and/or the doses to be investigated in Part 2 have been determined based on data from Part 1. Part 3 of the study is the open-label drug-drug interaction (DDI) cohort to evaluate the effect of MT-4561 on the PK established in Part 1. A retrospective analysis will also be conducted to assess the correlation between efficacy and expression of BRD4/its downstream gene products in patient samples to explore predictive biomarkers. MT-4561 is administered as an intravenous (IV) infusion over 30 minutes once every week in 28-day cycles, until disease progression or discontinuation criteria are met. Parts 1 and 3 of the study will enroll patients 18 years and older with who have failed at least 1 therapy , who have $\geq$ 1 measurable lesion by RECIST v1.1 and with confirmed histologic or cytologic diagnosis of one of the following tumors: HNSCC, NSCLC, esophageal cancer, gastric cancer, biliary tract cancer, PDAC, breast cancer, ovarian cancer, cervical cancer, endometrial cancer, prostate cancer, urothelial carcinoma, NET or NEC, soft tissue sarcoma, and NUT carcinoma. Part 2 will enroll only pre-specified tumors for dose optimization to determine the RP2D. Key exclusion criteria include patients with unresolved $\geq$ Grade 2 toxicities from previous treatment and those with QTc prolongation $>$ 470 msec at screening. Also, patients who received drugs with a known risk of QT interval prolongation or torsade de pointes, before the start of IMP administration. Enrollment in Part 1 of the study began May 2025 and continues to enroll patients in the US and Japan with 10 patients enrolled through Dose Level 2 as of Jan 2026. The safety data along with DLT continues to be reviewed in Part 1. Ooike S, et al. PB069, Poster Session, 36th EORTC-NCI-AACR Symposium, 2024. Clinical trial information: NCT06943521. Research Sponsor: None.

TPS3179 **Poster Session**

A phase 1, first-in-human study of DS9051, a novel targeted protein degradation molecule, in patients with advanced/metastatic adrenocortical carcinoma (ACC) or metastatic castration-resistant prostate cancer (mCRPC). First Author: Manish R. Patel, Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, FL

Background: ACC and mCRPC are difficult-to-treat malignancies. mCRPC typically progresses despite androgen deprivation and androgen receptor pathway inhibitor (ARPI) therapy, with or without taxanes. Similarly, treatment options for ACC are limited and prognosis is generally unfavorable. DS9051 is a targeted protein degradation molecule that has been designed to selectively degrade a key protein involved in the development and progression of both ACC and mCRPC via a novel mechanism. It leverages the ubiquitin-proteasome system, where DS9051 acts as a bridge to link the target protein and E3 ligase, initiating ubiquitination and degradation of the target protein. **Methods:** DS9051-079 (NCT07189403) is a Phase 1, first-in-human, open-label, multicenter study of DS9051 (N≈40). Patients must be adults with histologically confirmed advanced or metastatic ACC (Stage III–IV) or mCRPC and an Eastern Cooperative Oncology Group performance status of 0 or 1. Patients with ACC must have measurable disease per Response Evaluation Criteria in Solid Tumours, version 1.1 (RECIST 1.1) that is not amenable to radical surgical resection or definitive radiotherapy. Further inclusion criteria for patients with mCRPC include prior treatment with $\geq$1 line of ARPI therapy for castration-sensitive or -resistant prostate cancer for $\geq$12 weeks and with $\geq$1 line of chemotherapy (or not amenable to chemotherapy). These patients must also have $\geq$1 of the following criteria: prostate-specific antigen (PSA) progression per Prostate Cancer Working Group 3 (PCWG3) criteria, bone disease progression per PCWG3 criteria, or soft tissue disease progression per RECIST 1.1. Patients will receive DS9051 orally at escalating doses. The primary objective is to assess the safety and tolerability of DS9051 and to determine the maximum tolerated dose and/or recommended dose for expansion. Safety endpoints include dose-limiting toxicities and treatment-emergent adverse events. Secondary endpoints for both tumor types include objective response rate, disease control rate, clinical benefit rate, and duration of response (all assessed by the investigator, per RECIST 1.1 for ACC and per PCWG3 criteria for mCRPC); for ACC, progression-free survival (PFS) will be assessed by the investigator per RECIST 1.1, and for mCRPC, radiographic PFS and PSA decline will be assessed by the investigator per PCWG3 criteria. Enrollment is ongoing. Clinical trial information: NCT07189403. Research Sponsor: Daiichi Sankyo.

TPS3180 **Poster Session**

A phase 1, first-in-human, open-label, dose-escalation and -expansion study of gamitrinib, a first-in-class, mitochondria-directed inhibitor of the molecular chaperone heat shock protein-90 (Hsp90) in patients with advanced cancer. First Author: Anthony J. Olszanski, Fox Chase Cancer Center, Philadelphia, PA

Background: Mitochondria are subcellular organelles whose signaling and bioenergetics functions are exploited in cancer. This requires tight control of intra-organelle protein folding, which is made possible by the accumulation of molecular chaperones of the Heat Shock Protein-90 (Hsp90) family in mitochondria of tumors, but not normal tissues. This provides a unique therapeutic opportunity to disable multiple tumor pathways at once, but previously developed Hsp90 inhibitors do not accumulate in mitochondria, and systemic inhibition of chaperone activity is toxic in humans. Gamitrinib is a first-in-class anticancer agent specifically designed to disrupt protein folding in mitochondria, combining the Hsp90 inhibitory backbone of 17-allylamino-geldanamycin (17-AAG) to the mitochondria-targeting moiety, triphenylphosphonium. Gamitrinib selectively accumulates in mitochondria, does not affect the function of cytosolic Hsp90, and irreversibly disrupts organelle protein folding with activation of multiple cell death pathways. In preclinical studies, Gamitrinib shows potent, cytotoxic activity against multiple cancer cell types (IC_{50} 0.16–29 μM), inhibits primary and metastatic tumor growth in xenograft and genetic mouse models, has slower clearance (85.6 $\pm$ 5.8 mL/min/kg) and longer half-life (12.2 $\pm$ 1.55 h) than unconjugated 17-AAG, and is well-tolerated with no alterations in clinical-chemistry parameters, organ function, or tissue histology at dose levels of up to 5 (rats)- and 12 (dogs)-fold higher than therapeutically effective doses in mice (Cancer Biol Ther 23:117). **Methods:** Based on preclinical activity, favorable safety, and unique mechanism of anticancer activity, a first-in-human, open-label, dose-escalation phase 1 trial of Gamitrinib in sequential cohorts of adult patients with advanced solid tumors or lymphoma, for whom no standard therapy is available, was initiated (NCT04827810). Per study protocol, Gamitrinib is administered as a 1-h weekly intravenous (IV) injection on a 28 day-cycle with a 3+3 dose-escalation design and dosing continuing until disease progression, unacceptable toxicity, or patient discontinuation for any other reason. Trial objectives include determination of MTD and/or RP2D, overall safety, PK profile, correlative studies of target engagement in paired pre- and post-treatment biopsies in a 6-patient expansion cohort at MTD and documentation of anti-tumor activity by RECIST 1.1 and RECIL 2017 criteria. As of 2026, 18 evaluable patients have been accrued over 5 escalating Gamitrinib dose levels (10-85 mg) with no DLTs as assessed by NCI CTCAE v5.0 grading. 336 plasma samples have been collected for PK analysis. The study is currently open and enrollment is ongoing. Clinical trial information: NCT04827810. Research Sponsor: Gateway Foundation.

TPS3181 **Poster Session**

Phase Ib study of POLQ inhibitor SYN818 combined with olaparib in advanced solid tumors. First Author: Hongxia Wang, Fudan University Shanghai Cancer Center, Shanghai, China

Background: SYN818 is a selective, potent oral POLQ helicase inhibitor. POLQ is essential for microhomology-mediated end-joining and fills single-stranded DNA (ssDNA) gaps during replication. In tumors with homologous recombination repair (HRR) deficiencies (e.g., BRCA1/2 mutations), inhibition of PARP creates a dependency on POLQ for ssDNA gap filling, providing a synthetic lethal therapeutic strategy. Preclinically, SYN818 significantly enhanced the antitumor activity of Olaparib in breast and ovarian cancer models. Phase 1a monotherapy data demonstrate that SYN818 has a favorable pharmacokinetic profile and is well tolerated, supporting further evaluation of SYN818 in combination with Olaparib in HRR-deficient metastatic solid tumors. **Methods:** This phase 1b, open-label, multicenter study (NCT07156253; CTR20253189) evaluates SYN818 in combination with Olaparib in adults with locally advanced or metastatic solid tumors harboring BRCA mutations and/or homologous recombination repair (HRR) deficiency. During dose escalation (Part 1), patients receive escalating doses of SYN818 in combination with Olaparib (300 mg BID) administered in 21-day cycles to determine the recommended Phase 2 dose (RP2D), guided by a Bayesian dose-finding model. In the dose-expansion phase (Part 2), tumor-specific cohorts, including ovarian cancer and HER2-negative breast cancer, will further assess safety and preliminary antitumor activity at the RP2D. The primary objectives are to evaluate safety, tolerability, and determine the RP2D. Secondary objectives include characterization of pharmacokinetics, pharmacodynamics, and preliminary antitumor activity per RECIST v1.1. Key eligibility criteria include age $\geq$18 years, ECOG performance status 0–1, documented BRCA mutation and/or HRR deficiency, and adequate organ function. Prior PARP inhibitor therapy is permitted. Enrollment initiated in September 2025. Clinical trial information: NCT07156253. Research Sponsor: None.

TPS3182 **Poster Session**

IDE892 as monotherapy and in combination with IDE397 in patients with 5-methylthioadenosine phosphorylase-deleted (*MTAP*-Del) advanced solid tumors (IDE892001): Phase 1 trial. First Author: Benjamin Garmezy, Genitourinary Research Program, Sarah Cannon Research Institute, Nashville, TN

Background: MTAP deletion in solid tumors causes intracellular accumulation of methylthioadenosine (MTA) which partially inhibits activity of the key methylating enzyme, protein arginine methyltransferase 5 (PRMT5) and creates synthetic lethal dependencies on PRMT5 and methionine adenosyltransferase 2A (MAT2A), the rate limiting step in the synthesis of PRMT5 substrate, S-adenosyl methionine. PRMT5 and MAT2A are essential to transcription modulation, gene splicing, and DNA damage response. IDE892 is an MTA-cooperative PRMT5 inhibitor designed to exploit this vulnerability in MTAPdel tumors. Preclinical studies report robust antitumor activity with IDE892 monotherapy in MTAPdel xenograft models and an enhanced response when combined with IDE397 (an allosteric MAT2A inhibitor). IDE892-001 is a Phase 1 study evaluating safety, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of IDE892 alone and in combination with IDE397. **Methods:** IDE892-001 is an ongoing, open-label, multicenter four-part study: IDE892 monotherapy dose escalation (Part 1), monotherapy dose expansion in MTAPdel NSCLC (Part 2), IDE892 + IDE397 dose escalation (Part 3), and combination expansion in MTAPdel NSCLC (Part 4). Adults with advanced or metastatic MTAPdel solid tumors including lung, urothelial, gastrointestinal cancers (including pancreatic and biliary tract cancers) and mesothelioma are eligible following disease progression on standard therapies. Key exclusion criteria include symptomatic brain metastases, cardiac disease, active severe infection, and prior treatment with a PRMT5 or MAT2A inhibitor. Part 1 uses a Bayesian optimal interval design to determine maximum tolerated dose (MTD) and recommended doses for expansion (RDE). Part 3 uses a modified toxicity probability interval design to evaluate escalating combinations of IDE892 and IDE397. Oral treatment is given QD in 21-day cycles until progression or unacceptable toxicity. Serial blood samples are collected for PD analyses. Imaging will be performed every 6 weeks through week 24, then every 9–12 weeks. Efficacy endpoints will be assessed by RECIST v1.1. Primary objectives for dose-escalation cohorts (Parts 1 and 3) are safety and tolerability, including determination of MTD/RDE. In expansion cohorts (Parts 2 and 4), co-primary objectives include safety and preliminary antitumor activity (objective response rate and duration of response). Secondary endpoints for all parts include PK of IDE892 alone and in combination with IDE397. Exploratory assessments include progression free survival, changes in circulating and tumor-based markers of PRMT5 pathway modulation, molecular predictors of response, exposure–response relationships, and metabolite characterization. Clinical trial information: NCT07277413. Research Sponsor: IDEAYA Biosciences.

TPS3183 **Poster Session**

Study design of OMAHA-015: A phase 2 basket study of steroidogenesis inhibitor opevesostat in participants with selected solid tumors. First Author: Virginia G. Kaklamani, University of Texas Health Science Center at San Antonio, San Antonio, TX

Background: Opevesostat (MK-5684; ODM-208), an oral steroidogenesis inhibitor, selectively inhibits CYP11A1, blocking synthesis of all steroid hormones and their precursors, and may suppress steroid-driven tumor growth. The randomized, open-label, phase 2 OMAHA-015 trial (NCT06979596) is designed to evaluate the efficacy and safety of opevesostat compared with standard of care in breast, ovarian, and endometrial cancers. **Methods:** Cohort A will enroll participants (pts) with locally advanced unresectable or metastatic hormone receptor–positive (estrogen receptor and/or progesterone receptor $\geq$1% expression)/HER2-negative breast cancer (IHC 0, 1+ or 2+/ISH-) and disease progression on or after $\geq$1 prior endocrine-based therapy in the metastatic setting. Exclusion criteria include any line of cytotoxic chemotherapy (chemo) or PARP inhibitor in the inoperable or noncurative advanced/metastatic setting and prior treatment with both fulvestrant and exemestane in the metastatic setting. Cohort B will enroll pts with platinum-sensitive, histologically confirmed high-grade epithelial ovarian (including high-grade serous or predominantly serous, high-grade endometrioid, clear cell, or malignant mixed Müllerian tumors [carcinosarcoma]), fallopian tube, or primary peritoneal carcinomas. Pts must have received 4-8 cycles of platinum-based doublet chemo in a third-line setting for ovarian cancer with $\leq$9 weeks between the last dose of third-line chemo and randomization. Cohort C will enroll pts with histologically confirmed primary advanced or recurrent low-grade endometrioid carcinoma (FIGO grade 1/2, or well/moderately differentiated), with known pMMR status, and wild type p53 expression. Pts must either be treatment naive or have received 1 prior line of platinum-based therapy in the advanced/metastatic or adjuvant/neoadjuvant setting. In cohort A, ~80 pts will be randomized 1:1 to arm 1: opevesostat 5 mg PO twice daily (BID) + daily corticosteroids or arm 2: physician's decision of fulvestrant 500 mg IM (D1 and D15 of cycle 1 and D1 of each cycle thereafter) or exemestane 25 mg PO daily. Randomization will be stratified by 1 line versus $\geq$2 lines of prior endocrine therapy. In cohort B, ~90 pts will be randomized 1:1 to arm 3: opevesostat 5 mg PO BID + daily corticosteroids; or arm 4: observation. In cohort C, ~80 pts will be randomized 1:1 to arm 5: opevesostat 5 mg PO BID + daily corticosteroids; or arm 6: physician's choice of megestrol acetate 80 mg PO BID, alternating megestrol + tamoxifen 20 mg PO BID, or letrozole 2.5 mg PO daily. The primary end point is progression-free survival per RECIST v1.1 assessed by blinded independent central review (BICR). Secondary end points include overall survival, clinical benefit rate (cohort A only), objective response rate, and duration of response per RECIST v1.1 assessed by BICR, and safety. The study is currently enrolling. Clinical trial information: NCT06979596. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS3184 **Poster Session**

STELLA: A dose expansion of the ATR kinase inhibitor alnodesertib (ART0380) administered orally in combination with low-dose irinotecan to patients with advanced or metastatic CRC and PDAC. First Author: Kim Anna Reiss, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

Background: Replication stress (RS) creates cancer cell vulnerability to which the critical DNA damage response kinase, ATR (Ataxia-Telangiectasia and Rad3-related) responds. ATR senses the stress, halts the cell cycle, and promotes DNA repair to allow proliferation. Alnodesertib is an ATR inhibitor developed to prevent cancer cells from successfully repairing RS and proliferating further. In earlier stages of alnodesertib development, preclinical and translational research demonstrated that tumor cells experience three combined biological insults: irinotecan-induced RS, endogenous RS via ataxia-telangiectasia mutated (ATM) loss, and RS rescue prevention by ATR inhibition. Data from the dose escalation and initial dose expansion cohorts of this trial in a tumor agnostic population showed encouraging results in ATM-negative cancers (confirmed Overall Response Rate of 50% in 20 patients with ATM negative cancers and responses across 8 cancer types including complete responses, Ulahannan et al, AACR 2025). Tumor-specific dose expansion cohorts are now enrolling, including colorectal cancer (CRC) and pancreas ductal adenocarcinoma (PDAC). **Methods:** Two tumor-specific cohorts are now open, each enrolling approximately 50 patients (pts): ATM-negative CRC and ATM-negative PDAC. Pts will receive the recommended dose of alnodesertib 200mg orally on days 1-3 and 8-10 combined with low-dose irinotecan 60mg/m^2 IV on days 1 and 8, of each 21-day cycle. Tumor tissue is prescreened by immunohistochemistry for ATM protein loss (H score 0) for enrollment eligibility. Pts with CRC must have received a maximum of 2 prior chemotherapies excluding prior trifluridine/tipiracil, fruquintinib, or regorafenib, and pts with PDAC must have received a maximum of 1 prior chemotherapy for advanced disease. Prior targeted agents are allowed and do not count as prior lines of therapy. Key objectives include safety, tolerability, and preliminary efficacy. Clinical trial information: NCT04657068. Research Sponsor: Artios Pharma.

TPS3185 **Poster Session**

KANDLELIT-014: A phase 2 study of MK-1084 as monotherapy and in combination with cetuximab in *KRAS* G12C-mutant advanced solid tumors. First Author: Nehal J. Lakhani, START Center for Cancer Research, Grand Rapids, MI

Background: *KRAS* is one of the most frequently mutated oncogenes in human cancers, with the G12C mutant isoform accounting for ~15% of all *KRAS* mutations. Despite their promising antitumor activity and manageable safety profile in advanced solid tumors, first-generation KRAS G12C inhibitors are often limited by acquired resistance in the monotherapy setting. MK-1084 is a next-generation, highly potent and selective KRAS G12C–GDP covalent inhibitor that exerts downstream regulation of the MAPK pathway. EGFR-mediated reactivation of RAS-MAPK signaling is proposed as a key driver of resistance to KRAS G12C inhibitors, particularly in colorectal cancer (CRC). The combination of KRAS G12C inhibitors and EGFR-targeted monoclonal antibodies has demonstrated clinical benefit in *KRAS* G12C-mutated CRC and non-small cell lung cancer (NSCLC), supporting the potential of this mutation as a clinically-relevant target across tumor types. KANDLELIT-014 (NCT07209111) is a phase 2, randomized, open-label, multicenter, tumor-agnostic study of MK-1084 as monotherapy and in combination with EGFR inhibitor cetuximab in participants with previously treated advanced solid tumors harboring a *KRAS* G12C mutation. **Methods:** Eligible participants are aged ≥18 years with histological or blood-based *KRAS* G12C-mutated locally advanced unresectable or metastatic solid tumors (other than CRC) that have progressed on or following standard-of-care systemic treatment, or for whom no satisfactory alternative treatment options are available. Additional eligibility criteria include an ECOG PS score of 0 or 1 and measurable disease per RECIST v1.1. Participants were excluded if they had uncontrolled, significant cardiovascular or cerebrovascular diseases; an additional progressive active malignancy that required treatment within the past 3 years; or active CNS metastases, carcinomatous meningitis, or primary brain tumors. Participants will be randomly assigned 1:1 to receive MK-1084 100 mg orally once daily as monotherapy (Arm 1) or in combination with cetuximab 500 mg/m^2 intravenously every 2 weeks (Arm 2) until discontinuation criteria are met. Randomization will be stratified according to the following tumor groups: NSCLC, pancreatic ductal adenocarcinoma, endometrial cancer, biliary tract cancer, and other solid tumors. The primary end points are ORR per RECIST v1.1 as assessed by blinded independent central review (BICR), safety, and tolerability. Key secondary end points include OS, DOR per RECIST v1.1 by BICR, and PFS per RECIST v1.1 by BICR. Imaging will be performed every 6 weeks until Week 18, every 8 weeks until Week 50, and every 12 weeks thereafter until disease progression or discontinuation. AEs will be evaluated from randomization to 30 days after the last dose of study treatment per NCI CTCAE v5.0. This global study is actively enrolling. Clinical trial information: NCT07209111. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Informing optimal duration of adjuvant chemotherapy (ACT) in resected stage I-IV colorectal cancer (CRC) based on early circulating tumor DNA (ctDNA) dynamics. First Author: Hiroyuki Yamamoto, Teine Keijinkai Hospital, Sapporo, Japan

Background: While ACT is recommended by clinical guidelines for patients (pts) with high-risk stage II and stage III CRC, individual benefit varies significantly and appropriate ACT duration is debatable. Here, we evaluated whether on-ACT ctDNA dynamics can inform recurrence risk and benefit from continued ACT beyond 3 months (mo) in resected stage I-IV CRC. **Methods:** This analysis included 1,028 pts from the CIRCULATE-Japan GALAXY observational study who received ACT but no neoadjuvant chemotherapy, with >2 ctDNA results available within 6 mo post-surgery. Patients were divided into long-ACT (>3 mo, N = 651) and short-ACT cohort (< 3 mo, N = 377) cohorts. ctDNA was analyzed using a personalized, tumor-informed Signatera assay at two timepoints: a) pre-ACT (≥14 days post-surgery, before ACT), and b) post-3 mo from ACT (short cohort) or 3 mo ±45 days from ACT (long cohort). Disease-free survival (DFS) was measured from the date of surgery and compared between pts who received long vs short ACT, stratified by ctDNA dynamics. Subanalyses comparing ACT duration were landmarked at the second ctDNA timepoint. **Results:** Of the 1,028 pts (< 1%/17%/75%/7% stages I/II/III/IV), 44% were females; 81% had colon cancer and 19% rectal cancer. Median pt age was 66 (24-89) years. Median follow-up was 30.7 (4.9-55.8) mo. Median ACT duration was 5.7 mo in long-ACT and 2.5 mo in short-ACT cohorts. Pre-ACT sampling was a median of 14 and 20 days before ACT start for long- and short-ACT cohorts, respectively; post-3 mo sampling was a median of 112 days after ACT start for both cohorts. ctDNA dynamics from the pre-ACT to post-3 mo ACT timepoints revealed sustained negativity in 78.7% (N = 809) of pts, ctDNA clearance in 14.7% (N = 151), decreasing but detectable levels in 2.7% (N = 28), rising levels in 2.8% (N = 29), and newly detectable ctDNA on ACT in 1.1% (N = 11). No benefit of short vs long ACT duration was observed among pts with sustained ctDNA negativity (HR 0.71, p = 0.11) or ctDNA clearance (HR 1.06, p = 0.84). Similarly, pts with rising ctDNA experienced no benefit from longer ACT (HR 1.82, p = 0.18). Conversely, within the decreasing but detectable ctDNA subgroup, longer ACT was associated with improved DFS compared with short ACT median DFS 5.9 vs 1.7 mo; HR 3.64, p = 0.012), acknowledging that the analysis was limited by small cohort size and requires further investigation. **Conclusions:** ctDNA dynamics during ACT provide clinically meaningful stratification of recurrence risk and reveal heterogeneity in treatment benefit. Pts with ctDNA clearance or sustained negativity showed durable disease control and may not require longer ACT. Conversely, pts with partial molecular response showed directional benefit from longer ACT. Pts with molecular progression on ACT did not benefit from extended ACT, indicative of chemotherapy refractory disease and the need for alternative treatment regimens. Clinical trial information: R000044197. Research Sponsor: None.

Observation versus maintenance PD-1 inhibitor therapy after clinical complete response in dMMR/MSI-H colorectal cancer managed with non-operative management: A multicentre cohort study. First Author: Xiaohang Gao, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University, Guangzhou, Guangdong, China

Background: Patients with mismatch repair–deficient (dMMR)/microsatellite instability–high (MSI-H) colorectal cancer (CRC) who achieve a clinical complete response (cCR) after PD-1 inhibitor therapy may undergo non-operative management (NOM) with active surveillance. We aimed to assess the necessity of maintenance immunotherapy after achieving cCR, with a focus on survival outcomes and the burden of immune-related toxicity. **Methods:** A multicentre observational cohort study was conducted at five tertiary hospitals in China between Jan 1, 2018, and March 21, 2025. Patients with dMMR/MSI-H CRC who achieved cCR after PD-1 inhibitor therapy and entered NOM were included. Patients were stratified into an observation group (discontinue PD-1 inhibitor after cCR) and a maintenance group (received ≥2 cycles of PD-1 inhibitors after cCR). Disease-free and overall survival were compared between groups using Kaplan–Meier methods with log-rank test, and local regrowth, distant metastasis, and immune-related adverse events were assessed. **Results:** Among 318 patients treated with PD-1 inhibitors, 195 (61·3%) achieved cCR. A total of 129 patients were analysed (observation n = 66; maintenance n = 63), including 58 with rectal cancer, 61 with colon cancer, and 10 with synchronous dual primary tumours; 14 had distant metastases at diagnosis. Clinical complete response was assessed with endoscopy and pelvic MRI/CT along with digital rectal examination for rectal cancer, and endoscopy with contrast-enhanced CT or PET/CT for colon cancer. Median PD-1 inhibitor exposure to achieve cCR was eight cycles in both groups; 69·8% achieved cCR within eight cycles. Median follow-up was 3·2 years (IQR 2·0–4·0). Local regrowth occurred in two patients in the observation group and none in the maintenance group, and no distant metastases were observed. The 3-year DFS was 96·4% (95% CI 91·6–100·0) in the observation group and 98·4% (95% CI 95·2–100·0) in the maintenance group (log-rank p = 0·55). The 3-year OS was 100·0% (95% CI 100·0–100·0) versus 98·4% (95% CI 95·2–100·0) (p = 0·34). Any-grade irAEs occurred in 42/66 (63·6%) versus 44/63 (69·8%); grade 3 irAEs were numerically higher with maintenance (7/63 [11·1%] vs 2/66 [3·0%]; p = 0·091). **Conclusions:** To our knowledge, this is the largest series of dMMR/MSI-H CRC patients achieving cCR after PD-1 inhibitor therapy and managed with NOM. Maintenance therapy after cCR did not provide a clear survival advantage but was associated with a higher burden of immune-related toxicity, supporting treatment discontinuation with close surveillance. Research Sponsor: None.

BREAKWATER: Progression-free and overall survival analyses of first-line (1L) encorafenib + cetuximab (EC) + FOLFIRI in BRAF V600E-mutant metastatic colorectal cancer (mCRC). First Author: Scott Kopetz, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

3504 Oral Abstract Session

SWOG S2107: Randomized phase II trial of encorafenib and cetuximab with or without nivolumab for patients with previously treated MSS, *BRAF*^{V600E} metastatic colorectal cancer (mCRC). First Author: Van K. Morris II, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: *BRAF*^{V600E} mutations are associated with poor survival yet increased immune activation among patients (pts) with microsatellite stable (MSS) mCRC. A prior single-institution trial of the BRAF inhibitor encorafenib (E) with the anti-EGFR antibody cetuximab (C) and the anti-PD-1 antibody nivolumab (N) reported an overall response rate (ORR) of 50% and median progression-free survival (PFS) of 7.2 months in pts with MSS, *BRAF*^{V600E} mCRC, promising findings relative to historical controls with E+C. **Methods:** In this phase II SWOG/NCTN study (NCT05308446), pts with previously treated, MSS *BRAF*^{V600E} mCRC were randomized 2:1 to receive E (300 mg PO daily) + C (500 mg/m^2 IV every 2 weeks) + N (480 mg IV every 4 weeks) vs E+C only. No prior exposure to BRAF, EGFR, or immune checkpoint therapies were allowed. The primary endpoint was PFS and targeted a hazard ratio (HR) of 0.57 with a 1-sided α=0.10 and 80% power. Randomization was stratified by prior lines of therapy (1 vs 2) and Zubrod PS (0 vs 1). Treatment response was assessed every 8 weeks radiographically (RECIST 1.1). Secondary endpoints were overall survival (OS), ORR, and treatment-related adverse events (TRAE) according to CTCAE v5. Differences in PFS by treatment arm were assessed via stratified log-rank test. **Results:** Of 88 pts enrolled, 85 were eligible and evaluable (57 E+C+N, 28 E+C). Participant characteristics are listed in Table. Median PFS was 5.8 months (95% CI 4.0-7.8) with E+C+N and 6.3 months (95% CI 5.0-11.4; p=0.64) with E+C; HR 1.10 (95% CI 0.65-1.86). ORR was 35% for E+C+N and 32% for E+C. OS was similar between E+C+N and E+C: median 13.5 months (95% CI 11.0-18.9) vs. 11.6 months (95% CI 9.2-15.6; p=0.29); HR 0.85 (95% CI 0.47-1.52). 31 out of 57 pts (54%) had grade 3-4 TRAEs for E+C+N, vs 10 out of 28 (36%; p=0.11) for E+C; Grade 3 TRAEs occurring in >10% pts treated with E+C+N included fatigue (14%) and arthralgia (11%). **Conclusions:** The addition of N to E+C did not improve survival outcomes in this study population of pts with pretreated MSS, *BRAF*^{V600E} mCRC. Ongoing correlative studies seek to identify biomarkers associated with treatment benefit that may be applied to future efforts seeking to personalize treatment approaches for this biologically heterogeneous population. Clinical trial information: NCT05308446. Research Sponsor: NIH/NCI/NCTN; U10CA180888; NIH/NCI/NCTN; U10CA180819; Bristol-Myers Squibb.

3505 Oral Abstract Session

Phase 3 trial of trastuzumab rezetecan vs standard of care (SOC) for chemotherapy-refractory, HER2-positive, advanced colorectal cancer (CRC). First Author: Jin Li, Shanghai GoBroad Cancer Hospital, China Pharmaceutical University, Shanghai, China

Background: Antibody-drug conjugate (ADC) targeting HER2 represents standard therapy for HER2-positive gastric cancer and breast cancer. This study aimed to assess trastuzumab rezetecan (an HER2-targeted ADC) vs SOC in patients (pts) with chemotherapy-refractory, HER2-positive, RAS and RAF wild-type advanced CRC. **Methods:** In this randomized, open-label, multicenter, phase 3 trial, pts with HER2-positive, RAS and RAF wild-type, advanced CRC who have progressed after standard 2nd-line therapy were randomized 2:1 to receive trastuzumab rezetecan (4.8 mg/kg, d1, iv, q3w) or SOC (TAS-102 [35 mg/m^2, bid, d1-5 and d8-12], fruquintinib [5 mg, qd, d1-21], or regorafenib [160 mg, qd, d1-21]; po, q4w). Randomization was stratified by HER2 status (IHC 3+ vs IHC 2+/ISH+) and ECOG PS (0 vs 1). Primary endpoint was PFS per RECIST v1.1 by independent review committee (IRC). Key secondary endpoint was OS. **Results:** As of data cutoff (Oct 31, 2025), 130 pts were randomly assigned to trastuzumab rezetecan (N=86) or SOC (N=44). 70.8% of pts had HER2 IHC 3+, and 57.7% had an ECOG PS of 1. Median follow-up was 9.6 mo (95% CI 7.4-10.7). PFS per IRC was significantly increased with trastuzumab rezetecan vs SOC (median 5.5 mo [95% CI 4.8-6.7] vs 2.8 mo [95% CI 2.2-4.2]; HR 0.33 [95% CI 0.21-0.53]; 1-sided p<0.0001). Although median OS were immature, risk of death with trastuzumab rezetecan was reduced by 23% compared with SOC (HR 0.77 [95% CI 0.35-1.73]). PFS per investigator, ORR and DoR were also better with trastuzumab rezetecan vs SOC (Table 1). Grade ≥3 TRAEs occurred in 48.8% with trastuzumab rezetecan and 50.0% with SOC. No patients discontinued treatment due to TRAEs. Treatment-related death was reported in two pts (2.3%) with trastuzumab rezetecan (septic shock and myelosuppression). **Conclusions:** Compared with SOC, trastuzumab rezetecan achieved prolonged PFS and improved ORR in chemotherapy-refractory HER2-positive advanced CRC, with a tolerable safety profile. Clinical trial information: NCT06199973. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

3507 Oral Abstract Session

Structured exercise program following adjuvant chemotherapy for colon cancer: A cost-utility analysis of the CHALLENGE trial. First Author: Kelvin K. Chan, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada

Background: The phase III CHALLENGE trial (CCTG CO.21) demonstrated improved disease-free and overall survival with a 3-year structured exercise program (SEP) compared with health education materials (HEM) in participants with stage III or high-risk stage II colon cancer that had undergone surgery and adjuvant chemotherapy. This study evaluated the cost-effectiveness of SEP versus HEM. **Methods:** A pre-specified economic evaluation was conducted using prospectively collected data from all trial participants (n = 889). The base case adopted the Canadian public healthcare payer perspective and included direct healthcare costs (cost categories available in Table 1), a 5-year time horizon, and a 1.5% discount rate. SF-36 trial data were mapped to SF-6D using a validated algorithm to calculate health utilities. Costs (2024 CAD) and effects measured as life-years (LYs) and quality-adjusted life-years (QALYs) were used to estimate an incremental cost-effectiveness ratio (ICER, $/life year gain (LYG)) and incremental cost-utility ratio (ICUR, $/QALY). Uncertainty was assessed via bootstrapping (n = 1,000). Notable scenario analyses included a 10-year horizon and a societal perspective capturing indirect costs from wages lost due to missed work, measured using a Work Productivity and Activity Impairment questionnaire. **Results:** In the base case, despite the up-front $4327 cost of the SEP intervention, the SEP was dominant over HEM (i.e less costly (−$179) and more effective (+0.06 LYs; +0.10 QALYs)). The SEP was dominant in 49% of bootstrap samples, while 79% met a $50,000 per QALY willingness-to-pay threshold. Major cost drivers in both groups were the costs of recurrence or new malignancy and anticancer therapy. Scenario analysis results were consistent with the base case analysis. The SEP remained dominant with a 10-year time horizon yielding greater cost savings ($-2,528) and more LYG (0.35) than the base case. From a societal perspective, the ICUR was $3,571/QALY, a highly cost-effective strategy. **Conclusions:** The SEP was less costly and more effective when compared with HEM. These data can inform health systems and payers as they look to implement SEP in routine models of care. Research Sponsor: None.

Mean per participant costs, effects, and ICER/ ICUR for the base case analysis.

	SEP (n=445)	HEM (n=444)	Increment
Cost of SEP sessions (including fixed start-up costs) ($)	4,327	0	4,327
Cost of hospitalization (pre- or without recurrence) ($)	3,593	3,092	501
Cost of recurrence or new malignancy (physicians, lab tests, drugs, hospitalizations, surgery, emergency room visits, home care)($)	12,732	15,772	-3,040
Cost of anticancer therapy ($)	12,660	14,582	-1,922
Cost of end-of-life care ($)	54	100	-46
Total cost ($)	33,367	33,546	-179
Total LYs	4.72	4.66	0.06
Total QALYs	3.84	3.75	0.09
ICER ($/LYG) and ICUR ($/QALY)	Dominant*		

*SEP is less costly and more effective than HEM.

Onvansertib plus standard-of-care chemotherapy plus bevacizumab in first-line RAS-mutated metastatic colorectal cancer (mCRC): Interim results from the phase 2 randomized CRDF-004 trial. First Author: Heinz-Josef Lenz, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA

Background: Patients with RAS-mutated mCRC have limited treatment options. Chemotherapy in combination with bevacizumab (Bev) has been the standard first-line treatment for the past two decades, yet the prognosis for these patients remains poor. Onvansertib (Onv), a selective PLK1 inhibitor, has previously demonstrated synergy with chemotherapy in the second line setting. The Phase 2 randomized CRDF-004 trial evaluated onvansertib plus standard-of-care (SoC; FOLFIRI or FOLFOX with Bev) in as first-line RAS-mutated mCRC. **Methods:** Patients with first-line KRAS or NRAS mutant mCRC were randomized to SoC alone or SoC plus onvansertib (20 mg or 30 mg). The primary endpoint was objective response rate (ORR) as determined by a blinded-independent central review (BICR) using RECIST v1.1. Key secondary endpoints included progression-free survival (PFS), duration of response, and safety. PFS was assessed by BICR and investigator assessments combined. Results are presented in the intent-to-treat population (ITT). **Results:** At the data cutoff of 22 Jan 2026,110 patients were randomized with a median follow up of approximately 10 months. Baseline characteristics were relatively balanced across arms. Onv 30 mg + FOLFIRI + Bev demonstrated numerically higher ORR (n = 13/18, 72.2%, 95% CI: 46.5, 90.3) compared with the FOLFIRI + Bev control arm (n = 8/19, 42.1%, 95% CI: 20.3, 66.5), the FOLFOX + Bev control arm (n = 8/18, 44.4%, 95% CI: 21.5, 69.2) and the combined control arms (SoC: n = 16/37, 43.2%, 95% CI: 27.1-60.5). Onv 30mg + FOLFIRI + Bev demonstrated a p-value of 0.051 for confirmed ORR vs. SoC; and a p-value of 0.045 for the 6-month ORR compared to FOLFIRI + Bev (n = 10/18, 55.6%, 95% CI: 30.8-78.5 vs. n = 4/19, 21.1%, 95% CI: 6.1-45.6, respectively). The median PFS for the control arms was 10.97 months (95% CI: 7.52, NR) for FOLFIRI + Bev, 9.89 months (95% CI: 9.43, NR) for FOLFOX + Bev and 10.97 months (95% CI: 9.43-15.44) for the combined SoC arms. The median PFS in the Onv 30mg+ FOLFIRI + Bev arm was not reached (95% CI: 9.72-NR). The PFS HR of 30mg + Onv +FOLFIRI + Bev vs FOLFIRI + Bev was 0.38 (95% CI: 0.12-1.17) and vs SoC was 0.37 (95% CI: 0.13-1.02, p = 0.048). The clinical benefit from Onv treatment was further evidenced by the 12-month PFS rates, 61.9% (95% CI: 40.1, 95.8) in the Onv 30 mg + FOLFIRI + Bev arm vs. 28.4% (95% CI: 9.3, 86.9) in the FOLFIRI + Bev arm, and 30.1% (95% CI: 13.8-65.7) in the SoC. Onvansertib was well tolerated, with no unexpected toxicities observed; the most common grade ≥3 adverse event was neutropenia. PK data support moving forward with the onvansertib 30mg dose with FOLFIRI + Bev. **Conclusions:** Onvansertib plus FOLFIRI and bevacizumab demonstrated improved antitumor activity and manageable safety in first-line RAS-mutated mCRC. These results support further clinical and support planned confirmatory Phase 3 evaluation. Clinical trial information: NCT06106308. Research Sponsor: Cardiff Oncology.

3511 **Rapid Oral Abstract Session**

Circulating tumor DNA (ctDNA) clearance as an early indicator of sotorasib + panitumumab efficacy and prognosis in *KRAS* G12C–mutated colorectal cancer (mCRC): Results from phase 3 CodeBreaK 300. First Author: Filippo Pietrantonio, Medical Oncology Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Phase 3 CodeBreaK 300 (NCT05198934) explored two doses of sotorasib (soto) (240 mg and 960 mg) in combination with panitumumab (pani) 6 mg/kg versus investigator's choice (IC) and demonstrated superior progression-free survival (PFS) with soto 960 mg+pani versus IC in chemorefractory *KRAS* G12C-mutant mCRC. We evaluated whether early ctDNA clearance could serve as non-invasive biomarker of treatment (tx) response using one of the largest cohorts of mCRC patients (pts) treated with a KRAS^{G12C} inhibitor plus an EGFR antibody and the only longitudinal ctDNA dataset from a KRAS^{G12C} inhibitor trial in mCRC. **Methods:** ctDNA analyzed using the Guardant Infinity assay was quantified using *KRAS* G12C variant allele frequency (VAF) and methylation-based circulating tumor fraction (cTF) metrics. Clearance was defined at ≥50%, ≥80%, ≥90% and 100% reduction thresholds. Associations with objective response rate (ORR), PFS, and overall survival (OS) were assessed using logistic regression, Fisher-exact tests, Cox proportional hazards models, and Kaplan–Meier methods. **Results:** A total of 142 pts had evaluable baseline and Cycle 2 Day 1 ctDNA results. Early ctDNA clearance was more frequent in the soto arms than in the IC arm. This finding was consistent across ctDNA assessment methods, with high concordance between VAF and cTF. At ≥80% threshold, VAF clearance rates (95% CI) were 77.3% (62.2–88.5) and 65.9% (50.1–79.5) in the soto 960 mg and 240 mg arms (each N=44), respectively, compared with 15% (5.7–29.8) in the IC arm (N=40). Complete (100%) VAF clearance (95% CI) was observed in 45.5% (30.4–61.2), 31.8% (18.6–47.6), and 5.0% (0.6–16.9) of pts in the 960 mg, 240 mg, and IC arms, respectively. Reductions in ctDNA were correlated with radiographic tumor shrinkage. Lack of ctDNA clearance was associated with non-response, whereas pts achieving clearance were more likely to respond. Among pts treated with soto 960 mg who achieved ≥80% ctDNA clearance, the ORR (95% CI) by VAF was 35.3% (12/34; 19.7–53.5) and 32.3% (10/31; 16.7–51.4) by cTF. Decline in ctDNA was associated with improved PFS and OS independent of tx arm, confirming the role of ctDNA as a prognostic marker. Increasing clearance stringency did not enhance prognostic value. **Conclusions:** Early ctDNA clearance, assessed by *KRAS* G12C VAF or cTF, is prognostic for improved outcomes, supporting its utility as an early response biomarker. Clinical trial information: NCT05198934. Research Sponsor: Amgen Inc.

Survival (months) by VAF clearance (≥80%).

Cohort	VAF Clearance	N	mPFS (95% CI)	mOS (95% CI)
IC	N	34	2.0 (1.9–4)	10.3 (6.6–14)
IC	Y	6	8.4 (3.7–NE)	NE

3512 Rapid Oral Abstract Session

Phase III CR-SEQUENCE trial of FOLFOX+panitumumab followed by FOLFIRI+bevacizumab (SEQ1) versus FOLFOX + bevacizumab followed by FOLFIRI + panitumumab (SEQ2) in previously untreated RAS wild-type, left-sided, unresectable metastatic colorectal cancer. First Author: Ramon Salazar, Medical Oncology Department, Institut Català d'Oncologia (ICO), L´Hospitalet De Llobregat, Barcelona, Spain

Background: The optimal sequencing of systemic therapy for patients with RAS wild-type, left-sided metastatic colorectal cancer (mCRC) remains under debate. This study evaluates whether starting with SEQ1 improves the 36-months progression-free survival rate (PFSR) versus SEQ2. **Methods:** Adult patients were randomized (1:1) to SEQ1 or SEQ2 and treated until second-line progression or unacceptable toxicity. Key inclusion criteria were untreated left-sided and wild type RAS (per local test) primary mCRC, ECOG-PS$<$2, measurable disease (RECIST 1.1), and adequate organ function. Primary endpoint was 36-month PFSR in ITT. Secondary endpoints included overall survival (OS), total PFS, objective response rate (ORR), PFS1, PFS2, and safety. **Results:** A total of 418 patients were analyzed (SEQ1=210; SEQ2=208); 54.76% and 70.19% of randomized patients received 2L treatment in SEQ1 and SEQ2 arms, respectively. The median follow-up was 62.2 months (95%CI 55.2 – 65.5). SEQ1 yielded a higher 1st-line ORR (80.95% vs 64.25%, p $<$0.01) and significantly improved median PFS1 (14.09 vs 12.39 months, p=0.03). In second line, SEQ2 (FOLFIRI + panitumumab) resulted in a higher ORR (40.43% vs 27.27%, p=0.03). There was no significant difference in 36-months PFS rate (28.57% vs. 22.36%; p=0.224). Median total PFS and OS were 22.93 vs 21.39 months (p=0.2241) and 36.57 vs 31.74 months (p=0.2949), respectively. Longer follow-up for PFS and OS is ongoing. Curative intent procedures were performed in 22.86% (SEQ1) and 19.23% (SEQ2) of patients, respectively. Rescue surgery improved PFS and OS across both sequences. Common related G3-4 adverse events included neutropenia (42%), rash (15.7%), diarrhea (13%), peripheral neuropathy (12%), and fatigue (12.3%). **Conclusions:** SEQ1 did not improve the 36-month PFSR versus SEQ2. However, starting with SEQ1 yielded superior early efficacy (higher ORR and longer PFS1), which may be clinically relevant in a subset of patients. Molecular profiling and genomic correlation analyses are ongoing to identify biologically defined clusters that may improve selection of sequential treatment strategies. Longer follow-up for clinically relevant secondary endpoints (total PFS and OS) is ongoing. Clinical trial information: 2024-510967-41-00. Research Sponsor: AMGEN.

3513 Rapid Oral Abstract Session

Development of a computational histology artificial intelligence (CHAI)–powered predictive biomarker for first-line chemotherapy intensification in metastatic colorectal cancer (mCRC) and validation in prospective randomized phase III trials (RCT). First Author: Paolo Ciracì, Unit of Medical Oncology 2, Azienda Ospedaliera Universitaria Pisana and Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy

Background: In unresectable mCRC, meta-analysis of RCTs suggests triplet therapy consisting of fluorouracil, oxaliplatin, and irinotecan (FOLFOXIRI) + bevacizumab (bev) may improve survival outcomes over doublet regimens of fluorouracil with irinotecan (FOLFIRI) or oxaliplatin (FOLFOX) + bev, at the expense of increased toxicity. Adoption of triplet therapy remains low. A histology-based biomarker to predict outcomes in mCRC treated with triplet vs doublet regimens could optimize treatment selection. We aimed to use the previously described CHAI platform to develop and validate a histology-based predictive biomarker for doublet vs triplet therapy in mCRC with participant-level data from 3 RCTs. **Methods:** Development used diagnostic H&E-stained whole slide images (WSI) from participants with mCRC treated with first-line (1L) chemotherapy enrolled in the MRC FOCUS RCT. WSIs were analyzed using the CHAI assay and trained towards clinical outcomes as a function of chemotherapy escalation. Weighting of histologic features was optimized for association with progression-free (PFS) & overall survival (OS) to construct a signature that was combined with tumor sidedness to create the mCRCpred biomarker. A cutpoint was selected to optimize treatment effect stratification, assigning each case a binary label. The locked biomarker was evaluated on the independent validation cohort of WSIs from the TRIBE + TRIBE2 RCTs. The association of the biomarker-treatment interaction with PFS & OS was evaluated with multivariable (MVA) Cox models & Likelihood Ratio tests. **Results:** The development cohort included 294 cases from MRC FOCUS. The independent validation cohort (n = 386) comprised cases from TRIBE (n = 159) and TRIBE2 (n = 227). 193 (50%) had 1L triplet+bev and 193 (50%) doublet+bev. Biomarker (+) (indicative of triplet benefit) disease treated with triplet+bev had superior 3-year PFS (17% vs 7%, HR = 0.51 [0.37, 0.70], p $<$ 0.001) and OS (43% vs 22%, HR = 0.51 [0.35, 0.73], p $<$ 0.001) versus doublet+bev. Biomarker (-) cases treated with triplet+bev vs doublet+bev had no significant differences in PFS (5 vs 15%, HR = 1.30 [0.96, 1.74], p = 0.09) or OS (31 vs 40%, HR = 1.35 [0.94, 1.92], p = 0.1). In MVA including cohort, age, ECOG, number of metastatic sites, and timing of metastasis (metachronous/synchronous), the biomarker-treatment interaction was significant (p $<$ 0.001) indicating a predictive association between the biomarker and treatment regimen. **Conclusions:** The CHAI mCRCpred histology-based biomarker predicted differential benefit of chemotherapy escalation (doublet-bev vs triplet-bev) as 1L therapy in mCRC, with independent validation post-hoc in two RCTs (Simons Level of Evidence IB). This biomarker may guide optimal treatment selection for 1L mCRC. Clinical trial information: ISRCTN79877428 (FOCUS); NCT00719797 (TRIBE); NCT02339116 (TRIBE2). Research Sponsor: None.

3514 Rapid Oral Abstract Session

Phase I study of intraperitoneal fast-manufactured IL-9-secreting CEACAM5-targeted CAR-T cells in advanced colorectal cancer with peritoneal metastases. First Author: Hangyu Zhang, Department of Medical Oncology, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: Colorectal cancer peritoneal metastasis (CRPM) remains an unmet clinical need with poor prognosis and limited benefit from systemic therapies. Our prior study on intraperitoneal (I.P.) CEA-targeting CAR-T cells (Nature Cancer) achieved a 25% ORR, yet limited persistence and exhaustion hampered efficacy. Consequently, we developed a novel Th9/Tc9-polarized fast- manufacturing process that exhibited superior T-cell fitness and antitumor function preclinically. We therefore conducted a Phase I study to evaluate the safety and preliminary efficacy of I.P. administration of these optimized CAR-T cells in CRPM population. **Methods:** This open-label, single-arm Phase I study enrolled patients with histologically confirmed, heavily pretreated CEA-positive CRPM. A standard 3+3 dose-escalation design evaluated three dose levels (DLs): DL1 (2.0×10^5 cells/kg), DL2 (3.0×10^5 cells/kg), and DL3 (4.0×10^5 cells/kg), followed by dose expansion. Primary objectives were safety and tolerability; secondary objectives included preliminary antitumor activity, cellular kinetics, and pharmacodynamics. **Results:** Between July 2024 and October 2025, 15 patients were enrolled; 14 were evaluable for efficacy. One dose-limiting toxicity (DLT; Grade 4 pneumonia) occurred at DL2. The most common grade 3 non-hematologic toxicity was diarrhea (53.3%). Cytokine release syndrome (CRS) occurred in all patients and was Grade 1/2 in 93.3%. No treatment-related deaths were reported. Among 14 efficacy-evaluable patients (median 3 prior lines of therapy), ORR was 57.1% and DCR was 100%, with maximum tumor shrinkage reaching 85.6%. Median PFS was 4.7 months (95% CI, 3.7–NE). Peripheral blood CAR- T cells expanded to a mean peak of 1.74×10^4copies/μg, and serum CEA levels decreased in 100% of patients (median reduction: 67.5%). **Conclusions:** Intraperitoneal administration of fast-manufactured Th9/Tc9 like CEACAM5-targeted CAR-T cells demonstrated a manageable safety profile and encouraging antitumor activity in heavily pretreated CRPM patients, at approximately one-tenth of conventionally reported CAR-T cell doses. These findings support further development of fitness-enhanced, regionally delivered CAR-T strategies for peritoneal malignancies. Clinical trial information: NCT05396300. Research Sponsor: None.

3516 Rapid Oral Abstract Session

Real-world outcomes and circulating tumor DNA (ctDNA) dynamics in patients (pts) with microsatellite instability–high (MSI-H) metastatic colorectal cancer (CRC) treated with immune checkpoint inhibitors (ICI). First Author: Hannah Ruth Robinson, Division of Medical Oncology, Department of Medicine, University of Colorado Anschutz School of Medicine, Aurora, CO

Background: ICIs produce durable benefit in MSI-H CRC, yet optimal treatment duration and monitoring strategies remain unclear. ctDNA enables minimally invasive assessment of molecular response during and after ICI. We evaluated real-world treatment patterns, outcomes, and longitudinal ctDNA dynamics in pts with MSI-H CRC treated with ICI. **Methods:** Pts with MSI-H mCRC treated with first-line ICI were identified from Natera's Real-World Database with linked longitudinal ctDNA results (Signatera, Natera, Inc.) and commercial claims data (Forian's Hybrid data ecosystem, CHRONOS). Overall survival (OS) was estimated using available mortality data (Veritas Data Research, Fact of Death Mortality Data Index). ctDNA status was assessed pre-ICI when available and longitudinally following ICI initiation. Outcomes included OS and time to next trmt (TTNT); ctDNA dynamics following ICI discontinuation were descriptively evaluated. **Results:** Among 559 pts treated with first line ICI (pembrolizumab [70.1%], ipilimumab+nivolumab [15.7%], and nivolumab [11.8%]), the median duration of ICI was 266 days. Baseline (pre-ICI) ctDNA results were available for 180 pts, including 38% who were treated with chemotherapy, and most pts (71.7%, 129/180) were ctDNA-positive (ctDNA(+)) prior to ICI initiation. Of these, 89.9% (116/129) had ctDNA-timepoints after the start of ICI, and 81.0% (94/116) achieved anytime ctDNA clearance (from ctDNA(+) to negative), while 19.0% (22/116) remained ctDNA(+). ctDNA(+) at anytime after the start of ICI (HR: 8.0, p $<$ 0.0001) or on first result after the start of ICI (HR: 3.4, p $<$ 0.0001) was associated with inferior OS compared ctDNA-negativity (ctDNA(-)) at these time points. Among pts whose first post-ICI test was ctDNA(+), 32% switched treatments, with a median TTNT of 302 days, compared to only 6.6% of pts (median TTNT 683 days) whose first post-ICI test was ctDNA(-). First post-ICI ctDNA status was associated with longer ICI duration (median 192 days for ctDNA(+) vs 303 days for ctDNA(-)), and ctDNA(+) was predictive of inferior OS (HR: 4.9; p $<$ 0.001). ctDNA after the end of ICI was available for 392 patients; it was persistently negative in 77.2% (303/392), persistently positive in 12.8% (50/392), cleared after the end of ICI (positive to persistently negative) in 4.1%, and the remaining 5.9% had variable patterns (e.g. positive to negative to positive). **Conclusions:** In this large real-world cohort of MSI-H mCRC treated with ICI, longitudinal ctDNA dynamics strongly correlated with treatment durability, time to subsequent therapy, and OS. These findings support further evaluation of ctDNA to inform treatment duration and surveillance strategies in MSI-H mCRC. Research Sponsor: None.

3518 Poster Session

Role of microbiota in response to treatment in anal squamous cell carcinoma. First Author: Jaime Feliú, Hospital Universitario La Paz, Madrid, Spain

Background: Anal squamous cell carcinoma (ASCC) is a rare tumor whose management and treatment have not changed since the 1970s, consisting of classical chemotherapy combined with radiotherapy. Microbiota has been recently included as a hallmark of cancer, playing a relevant role in oncogenesis and tumor progression. Therefore, the aim of this study is the characterization of tumor microbiota in ASCC. **Methods:** Paraffin samples from seventy-six ASCC patients were analyzed. First, DNA was extracted, followed by 16S rDNA sequencing to identify microbiota. Then, a bacterial reference proteome was built, including the bacteria genera identified by 16S, and proteins from human and microbiota were identified and quantified by mass-spectrometry proteomics. **Results:** Seventy-six ASCC patients were included in this study: 46 (60%) female; median age 61 years; 62 (81%) HPV-positive; 1 (1%) stage I, 30 (40%) stage II, 43 (57%) stage III, 1 (1%) stage IV, and 1 (1%) unknown stage. Of these, sixty-nine (stages II-III, treated with chemoradiotherapy) were considered for survival analyses. One thousand and fifty-seven bacteria genera were identified by 16S sequencing, with *Cutibacterium*, *Bacteroides*, and *Fusobacterium* being the most abundant. Using proteomics and after applying quality criteria, 1735 proteins were identified and quantified. Of them, 1727 were human proteins and eight were bacterial proteins. Two oncomicrobiota protein profiles were identified in ASCC, ASCC-OMP1 (36 [47%] pts) and ASCC-OMP2 (40 [53%] pts). ASCC-OMP1 presented a higher expression of proteins from *Sutterella* and *Staphylococcus* whereas ASCC-OMP2 showed higher expression of proteins from *Dialister*, *Campylobacter A*, and *Dysosmobacter*. In addition, the two microbiota profiles showed differences in human proteins related to immune response, adhesion, extracellular matrix, translation, and metabolism. Interestingly, significant differences in disease-free survival (DFS) (p=0.02, HR= 2.73, DFS at 5 years: ASCC-OMP1 78.43%, ASCC-OMP2 52.33%) were shown between ASCC-OMP1 and ASCC-OMP2. Overall survival (OS) is not significant between the two groups but a trend can be observed (p=0.06, HR=2.55, OS at 5 years: ASCC-OMP1 79.28%, ASCC-OMP2 62.92%). In a multivariate analysis including the classical clinical prognostic factors, the prognostic value in disease-free survival of the oncomicrobiota profiles remains. **Conclusions:** Two different oncomicrobiota protein profiles with implications in disease-free survival exist in anal squamous cell carcinoma. Research Sponsor: None.

3519 Poster Session

TROP2 as an actionable biomarker for anal cancer. First Author: Mir Lim, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Chemoimmunotherapy is standard frontline therapy for metastatic anal cancer, with no effective treatment options afterward. Mutation profiling has not yielded matched targeted therapies against anal cancer. Trophoblast cell-surface antigen 2 (TROP2) is overexpressed in other solid tumors, and TROP2 antibody-drug conjugates (ADCs) have demonstrated efficacy in breast and lung cancers. Given the therapeutic availability against TROP2, we evaluated expression of TROP2 in anal cancer as an actionable therapeutic target. **Methods:** Metastatic anal cancer tumors from 33 patients at MD Anderson were sequenced by bulk RNA sequencing ("Tumor Portrait" assay, Boston Gene) to quantify *TACSTD2* (TROP2) gene expression. *TACSTD2* expression was compared across all solid tumors and classified according to ranked expression percentile: high ($>83^{rd}$ percentile), medium (17-83^{rd} percentile), or low ($<17^{th}$ percentile). Gene expression (Nanostring) for >18,000 genes was measured using whole-genome digital spatial profiling (DSP) on a separate cohort of 40 chemoradiotherapy-refractory localized anal cancers collected at salvage surgery. *TACSTD2* gene expression on tumor cells vs TME cells was compared with a t-test (SPSS). TROP2 protein expression (Invitrogen) was quantified by H-score using immunohistochemistry (IHC) and correlated with *TACSTD2* expression via Spearman's correlation. Three patient-derived xenograft (PDX) models of anal cancer (C1411, C1436, O0026) were treated with normal saline (untreated control, UTC) or the TROP2 ADC sacituzumab govitecan (sac-gov; 10 mg/kg IP twice weekly). Tumor growth inhibition (TGI) was defined as 1 - (mean tumor volumes of sac-gov/UTC) at 21 days. **Results:** Median *TACSTD2* (TROP2) gene expression for patients with metastatic anal cancer was ranked at the 75^{th} percentile (IQR 63-85) relative to all solid tumors: 13/33 (39%) with high, 20/33 (61%) with medium, and none with low *TACSTD2* expression. For localized anal cancers, *TACSTD2* gene expression using DSP was significantly higher on tumor segments vs TME segments (log fold change 3.49, adjusted $p < 0.0001$). 30/39 (77%) anal cancers had high TROP2 expression by IHC, defined by H-score >200. Correlation between *TACSTD2* gene expression and TROP2 protein expression by IHC was observed (r= 0.43, $p < 0.001$). In PDX models, TGI with sac-gov relative to UTC was observed in both models with high TROP2 expression (C1411: TGI 54%, $p< 0.001$; C1436: TGI 52%, $p< 0.001$) but not in a model with no TROP2 expression (O0026: TGI 12%, p=n.s.). **Conclusions:** TROP2 expression is high for localized and metastatic anal cancer. *TACSTD2* gene expression correlates with matched TROP2 protein expression for anal cancer. Anti-tumor efficacy of TROP2 ADCs in vivo supports a forthcoming trial of sacituzumab tirumotecan for patients with treatment-refractory metastatic anal cancer, with the ultimate goal of establishing TROP2 as a predictive biomarker for treatment benefit in this rare cancer. H&E–based MSI/MMR testing with artificial intelligence in colorectal cancer: A blinded evaluation across diverse clinicopathological subgroups. First Author: Pahini Pandya, Panakeia Technologies, Cambridge, United Kingdom

Background: Mismatch repair (MMR) deficiency and microsatellite instability (MSI) testing is integral to colorectal cancer management. Despite guideline recommendations, routine testing remains limited by cost, turnaround time, and pathology resources. PANProfiler Colorectal (PPC) is an artificial intelligence (AI) system that infers MSI/MMR status directly from H&E-stained whole slide images (WSIs), offering a rapid, resource-efficient alternative. This study reports blinded validation of PPC, specifically evaluating performance across clinically relevant subgroups. **Methods:** A total of 2,636 WSIs from St. James's University Hospital (Leeds, UK) were retrospectively analyzed, with the dataset representing a broad range of clinicopathological characteristics including age (<50 to >75 years), gender, tumor stage, differentiation, and histological subtypes. PPC returned proficient MMR (*pMMR*), deficient MMR (*dMMR*) or *indeterminate* (no definitive result), with results evaluated for agreement against immunohistochemistry. **Results:** PPC generated definitive results for 2,109 WSIs, achieving a test replacement rate (TRR) of 80%. Overall positive percent agreement (PPA) was 97.9% and negative percent agreement (NPA) 93.8% (Table). Performance was consistent across all age groups and genders. PPA and NPA were mostly robust in all cancer stages, with PPA exceeding 99% in Stage II disease, where MMR status primarily informs adjuvant therapy decisions. In Stage III/IV disease, PPA reduced to 82.6%, which may reflect greater histological heterogeneity in advanced tumors. In mucinous and poorly differentiated tumors, PPA remained high (98.7-100%), supporting reliable detection of dMMR samples, while NPA ranged from 75.4-80%, indicating more conservative classification of pMMR tumors that would require lab tests. **Conclusions:** PPC demonstrated a high overall performance, providing definitive results for the majority of cases. PPA and NPA were consistent in key clinical groups, including younger patients and early stage disease. In more challenging cases like mucinous and poorly differentiated tumors, PPA remained robust despite reductions in NPA, supporting safe guidance of subsequent testing. These findings suggest PPC could streamline MSI/MMR workflows, reducing reliance on conventional testing while maintaining diagnostic safety across diverse clinicopathological profiles. Research Sponsor: None.

Large language model–assisted decision-making in multidisciplinary tumor boards for colorectal cancer. First Author: Aydan Farzaliyeva, Department of Medical Oncology, Baskent University, Ankara, Turkey

Background: Evolving colorectal cancer management and rising incidence have increased the workload of multidisciplinary tumor boards (MTBs), placing growing time demands on healthcare professionals. This study evaluates large language models (LLMs) as decision-support tools by comparing AI-generated recommendations with MTB decisions. **Methods:** This retrospective study used two large language models, Gemini 2.5 (general-purpose) and MedGemma 27B (medical-domain specific), to generate treatment recommendations for patients discussed at MTB. MedGemma 27B was evaluated at two temperature settings (T = 0.0 and T = 1.0). MTB decisions served as the reference standard. Agreement was quantified using Cohen's kappa, and classification performance was assessed with accuracy, F1 score, and recall. Recommendations were independently reviewed by two MTB members for clinical concordance and safety. **Results:** A total of 300 colorectal cancer cases were included. Gemini 2.5 demonstrated high agreement with MTB decisions (Cohen's kappa = 0.792, $p < 0.001$), with 81.7% full concordance, significantly outperforming MedGemma 27B at both temperature settings (57.0% at T = 0.0 and 62.3% at T = 1.0, $p < 0.001$ for both). MedGemma 27B showed moderate agreement (k = 0.566 at T = 0.0, k = 0.610 at T = 1.0, $p < 0.001$), with a modest improvement in concordance at T = 1.0 (p = 0.038). In safety, Gemini 2.5 had the highest rate of clinically safe recommendations (83.7%), outperforming MedGemma at both temperature settings ($p < 0.001$), with no significant safety difference between MedGemma's temperature settings (p = 0.567). Subgroup analyses showed that Gemini 2.5 had higher discordance in stage IV (p = 0.033), recurrent cases ($p < 0.001$), and surgical/interventional or active surveillance decisions ($p < 0.001$). In contrast, MedGemma demonstrated increased discordance in stage II ($p < 0.001$), ECOG PS ≥2 (p = 0.023–0.036), MSI-unstable tumors ($p < 0.001$), recurrent disease (p = 0.008–0.010), and surgical/interventional or active surveillance decisions ($p < 0.001$). **Conclusions:** Large language models demonstrated meaningful alignment with multidisciplinary tumor board decisions, supporting their potential role in clinical decision support for colorectal cancer, while emphasizing the need for further refinement to ensure consistent and safe clinical integration. Research Sponsor: None.

Comparison of large language models' agreement and performance metrics with multidisciplinary tumor board decisions in colorectal cancer.

LLM	Fully concordant	Partially concordant	Discordant	Accuracy	F1 score	Recall	Cohen's kappa (κ)	p value
Gemini 2.5	245 (81.7 %)	23 (7.7 %)	32 (10.7 %)	85 %	0.79	0.82	0.792	<0.001**
MedGemma 27B temperature 0.0	171 (57.0 %)	64 (21.3 %)	65 (21.7 %)	70.3%	0.64	0.61	0.566	<0.001**
MedGemma 27B temperature 1.0	187 (62.3 %)	54 (18.0 %)	59 (19.7 %)	73.5%	0.71	0.66	0.610	<0.001**

Inferring molecular signatures in colorectal cancer directly from routine whole-slide images. First Author: Piotr Keller, Predictive Systems in Biomedicine (PRISM) Lab, Department of Computer Science, University of Warwick, Coventry, United Kingdom

Background: Molecular profiling has advanced colorectal cancer (CRC) research but remains limited in the clinic due to cost and tissue constraints. In contrast, haematoxylin and eosin (H&E) whole-slide images (WSIs) are routinely available. Recent deep learning studies show that molecular signatures can be inferred from morphology. However, prediction of patient level pathway activity remains underexplored despite their pathobiological significance as coordinated drivers of cancer risk. **Methods:** We developed SPARROW, a neural network trained to predict over 200 molecular signatures from WSI graph representation of tumour, stroma, lymphocytic and mucosal regions in resection specimens. SPARROW was trained on TCGA (n = 585) and externally validated in the PETACC3 trial dataset (n = 1,160). It predicts pathway enrichment scores, point mutation and clinically actionable CRC subtypes. **Results:** As shown in the table below, SPARROW accurately predicts key molecular features of CRC directly from routine H&E slides and generalizes robustly to the independent PETACC3 trial. The strongest concordance was observed for biologically and clinically relevant programmes, including intrinsic consensus molecular subtype 3 (iCMS3) genes, Fetal enteric progenitor pathway genes, a 22-gene YAP/TAZ transcriptional target signature and epithelial-specific high-risk gene set (epiHR) activity. SPARROW also showed good performance for clinically used classifications, including iCMS/CMS subtypes, interferon phenotype and BRAF mutation status. Importantly, image-derived molecular scores were predictive of relapse free survival as well. **Conclusions:** SPARROW demonstrates that key molecular features of CRC, including transcriptomic subtypes and genomic alterations, are robustly encoded in and learnable from routine H&E histology. This enables histology to serve as a cost-effective and rapid surrogate for predicting key molecular signatures and actionable molecular subtypes while also allowing mining of spatially localised image signatures associated with transcriptional programmes. Research Sponsor: None.

Molecular Signature	TCGA (4-fold CV)	PETACC3 (external)	Relapse Free Survival Analysis (PETACC3)
iCMS3 (ρ)	0.64 ± 0.05	0.66	HR=1.2*, 95% CI:1.04-1.38
Fetal Mustata (ρ)	0.47 ± 0.06	0.61	HR=1.74*, 95% CI:1.45-2.08
YAP_22 (ρ)	0.41 ± 0.07	0.49	HR=2.54*, 95% CI:2.03-3.18
EpiHR (ρ)	0.40 ± 0.08	0.45	HR=1.59*, 95% CI:1.31-1.92
iCMS2 vs iCMS3 (AUC)	0.90 ± 0.02	0.92	HR=1.12, 95% CI:1.00-1.26
CMS (4 groups) (AUC)	0.84 ± 0.01	0.84	HR=6.3* (CMS4 vs other), 95% CI:3.92-10.01
Interferon (High/Low) (AUC)	0.82 ± 0.08	0.88	HR=1.14, 95% CI:0.86-1.05
BRAF Mutation (AUC)	0.82 ± 0.07	0.80	HR=2.12*, 95% CI:1.13-4.29

HistoChrome: Virtual multiplex immunohistochemistry from routine H&E in colorectal cancer. First Author: Mark Eastwood, Predictive Systems in Biomedicine (PRISM) Lab, Department of Computer Science, University of Warwick, Coventry, United Kingdom

Background: In colorectal cancer (CRC), immunohistochemistry (IHC) is central to assessment of spatial protein expression but is typically limited to few stains per case due to cost, tissue availability, and limited multiplexing. As a result, many relevant markers are not evaluated systematically. It remains unclear which pathobiologically relevant protein expression patterns are reliably encoded in morphological cues visible on routine haematoxylin and eosin (H&E) whole-slide images (WSIs). Markers of epithelial differentiation (CDX2, MUC2), immune infiltration (CD8), and mucin biology (MUC5) are clinically informative in colorectal cancer, yet their correspondence with H&E morphology is poorly defined. We investigate whether whole-slide virtual multiplex IHC (mIHC) can be generated from routine H&E for this marker panel. **Methods:** We trained a generative adversarial neural network with domain-specific constraints to enable whole-slide virtual mIHC generation from H&E. The model operates in stain concentration space using explicit stain separation and recombination and enforces spatial coherence during tiled whole-slide inference via an overlap consistency loss. Training used 52,579 paired H&E-mIHC patches (960×960 at 0.5 microns per pixel) extracted from adjacent, registered sections stained for CDX2, CD8, MUC2, MUC5, and hematoxylin, across 128 WSIs from 23 patients. Performance was evaluated on an independent cohort of 27 paired H&E-mIHC WSIs. **Results:** HistoChrome generates visually realistic and spatially coherent virtual mIHC WSIs from routine H&E. Biological fidelity was assessed by computing patch-wise Spearman correlations between mean stain intensities in real and virtual mIHC, restricted to tumor regions to avoid inflation from morphologically trivial normal tissue. Strong agreement with biological ground truth was observed for epithelial differentiation markers, with correlations of 0.79 for CDX2 and 0.63 for MUC2. CD8-positive immune infiltration was also captured with moderate accuracy (ρ = 0.49). In contrast, MUC5 expression showed only modest correspondence with biological ground truth (ρ = 0.25). **Conclusions:** HistoChrome enables whole-slide virtual multiplex immunohistochemistry from routine H&E, offering scalable access to biologically grounded protein markers without additional tissue or staining. Accurate inference of CDX2, MUC2, and CD8 supports slide-level pathological stratification of differentiation and immune contexts, with direct relevance for prognostic assessment and patient selection in therapeutic studies. The modest performance for MUC5 underscores that not all proteins may be morphologically encoded in H&E, highlighting the importance of marker-specific validation. Together, these findings position virtual mIHC as a practical adjunct to routine pathology and a discovery tool for CRC. Research Sponsor: None.

Validation of DiaSurv, an AI-based algorithm for stage II colon cancer risk stratification. First Author: Lou Rouan, Centre Hospitalier Universitaire de Caen, Caen, France

Background: Adjuvant chemotherapy decisions in stage II colon cancer (IIA T3N0; IIB T4aN0; IIC T4bN0) remain challenging, as conventional risk factors poorly predict recurrence. This results in both overtreatment and undertreatment. AI-based analysis of routine H&E slides may enable more accurate risk stratification to guide personalized treatment decisions. **Methods:** DiaSurv Colon is an AI-powered prognostic tool using a deep neural network to extract in an unsupervised way morphological features from H&E-stained WSI and predict 5-year overall survival (OS). Each patient is assigned an individual survival risk score. The model was trained on the TCGA cohort (n = 463) and previously validated on two external cohorts. In this study, we evaluated its performance on two new independent external cohorts, digitized with two different scanners: CHU Caen (n = 201; 5-y OS 47%, 95%CI 39-53%) and IHP (n = 207; 5-y OS 54%, 95%CI 45-61%). Prognostic accuracy was assessed using concordance index (c-index). Multivariate Cox regression and log-rank tests with hazard ratios (HR) were used to compare DiaSurv Colon performance against conventional clinicopathological factors. **Results:** On external validation, DiaSurv Colon achieved a c-index of 58 (CHU Caen) and 64 (IHP). The AI-based risk score significantly stratified patients: 5-year OS was 64% (95%CI 50-75%) vs 40% (95%CI 32-48%) for low- vs high-risk groups in CHU Caen ($p < 0.01$), and 64% (95%CI 52-73%) vs 39% (95%CI 26-51%) in IHP ($p < 0.001$). The risk score demonstrated strong prognostic value with hazard ratios of 1.29 (95%CI 1.05-1.58, $p < 0.01$) and 1.57 (95%CI 1.23-2.00, $p < 0.001$) for CHU Caen and IHP, respectively. **Conclusions:** DiaSurv Colon demonstrated consistent prognostic performance across independent external cohorts, with robust hazard ratios and concordance indices. This AI-based tool may improve risk stratification in stage II colon cancer and support personalized adjuvant therapy decisions with more confidence. Research Sponsor: None.

A deep learning approach to quantify tumor microenvironment features associated with postoperative ctDNA status and outcomes in a phase III FOLFOX-based adjuvant colon cancer trial (N0147; Alliance). First Author: Frank A. Sinicrope, Mayo Clinic Rochester, Rochester, MN

Background: Tumor microenvironment (TME) features of colorectal cancer (CRC) may influence detection of circulating tumor DNA (ctDNA) and further refine prognosis. We applied a deep learning histopathologic algorithm to quantify TME features in stage III colon cancers and evaluated their association with postoperative ctDNA status among participants in a phase III FOLFOX-based adjuvant trial (NCCTG N0147). **Methods:** QuantCRC (Aiforia Technologies) was applied to digitized hematoxylin and eosin-stained whole-slide images of stage III colon adenocarcinomas to extract quantitative histopathologic features. Among cases where data met quality control (N=1817), associations between 15 distinct pathologist-defined features and clinical outcomes—time to recurrence (TTR), disease-free survival (DFS), and overall survival (OS)—were evaluated, stratified by postoperative ctDNA status assessed by a tissue-free assay (Guardant Reveal). Relationships were analyzed using univariate and multivariable Cox proportional hazards models that were adjusted for clinicopathologic and molecular features (*KRAS*, *BRAF*^{V600E}, MMR status). Interaction testing was performed. **Results:** We found statistically significant quantitative differences for histopathological features by ctDNA status. Features associated with ctDNA positivity(+) included lymphovascular invasion (LVI), and increased %high grade, %tumor budding, %necrosis, and %stroma. ctDNA+ cases had lower %inflammatory stroma and fewer %signet ring cells (all $p < 0.006$). Multivariable analyses, irrespective of ctDNA status, identified % tumor budding, %mucin, %signet ring cells, %inflammatory tumor bed, and %inflammatory stroma as significantly associated with adverse outcomes (TTR, DFS, OS). Within ctDNA+ cases, higher %immature tumor bed was associated with adverse outcome for all 3 variables. Among ctDNA-negative cases, significantly poorer outcomes (TTR, DFS, OS) were observed for tumors with lower tumor infiltrating lymphocyte (TIL) density and reduced %necrosis. After adjustment, significant interactions with ctDNA status were observed for LVI ($p < 0.006$) and %signet ring cells ($p < 0.035$) across all outcome variables, for %necrosis with DFS, OS ($p<0.040$), and for TILs with TTR ($p<0.015$). Analysis is ongoing for ctDNA tumor fraction as well as tumor genotyping data (739 genes; Guardant360). **Conclusions:** QuantCRC identifies TME features associated with postoperative ctDNA status that enable risk-stratification within ctDNA groups. Among ctDNA-negative patients, reduced intratumoral TIL density and reduced tumor necrosis identify high-risk subgroups with inferior clinical outcomes, and may have clinical utility. Research Sponsor: None.

A large-scale, multi-target deep learning model for virtual genomic and molecular risk profiling in colorectal cancer. First Author: Erik N. Bergstrom, Natera, Inc., Austin, TX

Background: Molecular profiling of tumor biopsies is central to precision oncology, informing treatment selection, prognostication, and disease monitoring. Computational analysis of routine H&E slides offers a complementary, scalable approach that can accelerate biological insights and optimize downstream molecular testing. Recent advances in computational pathology have demonstrated that deep learning models can infer molecular features directly from digital H&E images, referred to as virtual genomics. However, most studies in colorectal cancer (CRC) have been constrained by limited cohort sizes, single-target predictions, and a lack of integration with longitudinal clinical outcomes. Here, we present a transformer-based deep learning framework designed for large-scale virtual genomic and molecular recurrence risk profiling in CRC. **Methods:** The model was trained on 45,155 patients with matched digital H&E images, whole-exome sequencing (WES), and longitudinal circulating tumor DNA (ctDNA) for molecular recurrence monitoring. We embedded all images using H-optimus-0 and trained a transformer-based multiple instance learning aggregation head for downstream virtual genomic predictions. We trained individual models to predict genes found in the MSK-IMPACT505 cancer gene panel and a single model that predicts all genes simultaneously. Lastly, we trained an independent model to predict the risk of molecular recurrence. All results were validated on an external cohort from The Cancer Genome Atlas (TCGA; n = 422 CRC patients). **Results:** Individual models predicted 379 mutated genes with an internal area under the receiver operating curve (AUROC) $>$ 0.7. We validated 254 of these genes within TCGA with an AUROC $>$ 0.7. Training a multi-task learning model to predict all genes simultaneously improved the AUROC for 85% of the genes. Based on NCCN guidelines in CRC, we further trained individual models to predict MSI status, BRAF V600E, KRAS G12D/V/G13D, and POLE/POLD1 exonuclease mutations with AUROCs of 0.96, 0.93, 0.84, and 0.86, respectively. Lastly, we developed an image-based molecular recurrence risk model trained directly on longitudinal ctDNA outcomes. The model stratified patients into low, medium, and high risk groups with a concordance index of 0.67. Compared to low-risk patients, the high-risk group exhibited a hazard ratio (HR) of 4.67, while the medium-risk group showed an HR of 1.98 (p-values $<<$ 1E-5). **Conclusions:** This unified framework demonstrates that virtual genomics from routine H&E histopathology can enable scalable, cost-efficient inference of hundreds of clinically relevant genomic alterations and molecular recurrence risk in CRC. By leveraging universally available diagnostic slides, virtual genomics has the potential to expand access to precision oncology, optimize molecular testing strategies, and support earlier risk stratification. The use of miR-5193 to predict oxaliplatin chemosensitivity in colorectal cancer: Integrated in silico, in vitro, and clinical evidence. First Author: Jaime A. González Montero, Bradford Hill Clinical Research Center, Santiago, Chile

Background: Outcomes with first-line chemotherapy in metastatic colorectal cancer (mCRC) are heterogeneous. We evaluated whether tumor microRNA miR-5193 is a predictive marker of chemosensitivity. **Methods:** We performed (i) a discovery analysis in TCGA COAD/READ to test associations between tumor miR-5193 and progression-free (PFS) and overall survival (OS) by Kaplan–Meier/log-rank; (ii) functional assays in colonic epithelium (CON-841) and colorectal cancer cell lines (Caco-2, HCT116) after miR-5193 mimic transfection, assessing 5-fluorouracil (5-FU) and oxaliplatin (L-OHP) sensitivity by MTT and IC50; and (iii) a validation cohort of formalin-fixed paraffin-embedded (FFPE) primary tumors from Chilean mCRC patients (n=50) in which hsa-miR-5193 was quantified by RT-qPCR. Patients were dichotomized into low vs high expression, and PFS/OS were estimated by Kaplan–Meier/log-rank in the overall cohort and in prespecified oxaliplatin- and irinotecan-based first-line subgroups. **Results:** In TCGA mCRC cases selected for standard clinicopathologic features and chemotherapy exposure, low tumor miR-5193 expression was associated with shorter PFS (p=0.03). In vitro, miR-5193 was downregulated in CRC lines vs CON-841, and transient miR-5193 overexpression increased chemosensitivity to 5-FU (Caco-2; reduced viability at 200–250 μM and IC50 from 1138 to 345 μM, p=0.049) and oxaliplatin (HCT116; left-shifted dose–response and ~30–35% IC50 reduction, p$<$0.01). In the Chilean validation cohort, low (n=30) vs high (n=20) hsa-miR-5193 expression was associated with inferior OS (p=0.0081) and showed no statistically significant difference in PFS (p=0.058). Among patients receiving oxaliplatin-based first-line chemotherapy (FOLFOX/CAPEOX), low hsa-miR-5193 predicted shorter PFS (p=0.012), whereas no PFS difference was observed with irinotecan-based regimens (p=0.8104) (Table 1). **Conclusions:** miR-5193 appears to modulate chemosensitivity in mCRC. Low tumor miR-5193 is linked to reduced oxaliplatin and 5-FU sensitivity in vitro, and shorter PFS/OS under oxaliplatin-based therapy, supporting its role as a biomarker of oxaliplatin sensitivity. Prospective validation could enable miR-5193-guided treatment selection and risk stratification, particularly for patients considered for oxaliplatin-containing regimens. Research Sponsor: Agencia Nacional de Investigación y Desarrollo (ANID); SA20I0059; FONDAP; 152220002; Agencia Nacional de Investigación y Desarrollo (ANID); 21240251.

Association between hsa-miR-5193 expression and clinical outcomes in metastatic colorectal cancer.

Study cohort / subgroup	Outcome	miR5193 expression: Low (n=30) vs high (n=20)	P-value
Chilean validation cohort — Overall	PFS	No significant difference	0,058 (NS)
Chilean validation cohort — Overall	OS	Shorter OS	0,0081
FOLFOX/CAPEOX subgroup (oxaliplatin-based)	PFS	Shorter PFS	0,012
Irinotecan-based subgroup	PFS	No difference	0,8104 (NS)

Fruquintinib plus FOLFIRI or mFOLFOX6 as second-line therapy for patients with *RAS*-mutant metastatic colorectal cancer (mCRC): A phase II, multicenter, open-label study. First Author: Yun Xu, Department of Colorectal Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Nearly half of metastatic colorectal cancer (mCRC) patients harbor RAS mutations, and the standard second-line regimen for this substantial subgroup of patients is combination chemotherapy (FOLFIRI/FOLFOX) with bevacizumab, which offers limited efficacy. Fruquintinib, an oral VEGFR-1, -2, and -3 inhibitor, has shown efficacy in refractory mCRC. This study evaluated the efficacy and safety of fruquintinib in combination with FOLFIRI or FOLFOX as second-line therapy for patients with RAS-mutant mCRC. **Methods:** This multicenter, open-label, single-arm phase II trial enrolled patients with RAS mutant mCRC who had failed first-line standard therapy. Participants received fruquintinib (4 mg once daily, days 1-21) plus FOLFIRI or mFOLFOX every 28 days. The primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), disease control rate (DCR), overall survival (OS), and safety. **Results:** As of Nov 11, 2025, 42 eligible pts were enrolled and received at least one cycle of treatment. Baseline characteristics included median age (63.0 [range: 35-74]), male (59.5%), ECOG PS 1 (66.7%), left-sided (73.8%), liver metastasis (59.5%), prior anti-VEGF therapies (73.8%). The median PFS was 8.1 months (95% CI: 6.18, 9.46) and median OS was not reached yet. The Kaplan-Meier estimates for PFS rates at 3, 6, 9, and 12 months were 85.3%, 73.5%, 35.9%, and 15.4%, respectively. In the subgroup analysis, median PFS were longer in pts without liver metastases (8.4mo vs 6.4mo, HR: 1.65, 95%CI: 0.65-4.18), those with left-sided lesion (8.1mo vs 4.8mo, HR: 2.14, 95%CI: 0.79-5.77) and pts without prior anti-VEGF therapies (8.4mo vs 6.5mo, HR: 1.79, 95%CI: 0.59-5.36). The ORR was 52.5% (21/40) which consisted of CR 5% and PR 47.5%. The DCR was 97.5% (39/40). Additionally, the most common any grade treatment-emergent adverse events (TEAEs) were hypertension (23.8%), diarrhea (19.1%), and mucositis (19.1%). Grade ≥3 TEAEs was 14.3% including diarrhea (4.8%), intestinal obstruction (2.4%) and leukopenia (2.4%). **Conclusions:** Fruquintinib combined with either FOLFIRI or mFOLFOX6 as second-line therapy for patients with RAS-mutant metastatic colorectal cancer (mCRC) demonstrated promising efficacy and a manageable safety profile. Clinical trial information: NCT05634590. Research Sponsor: None.

daNIS-3: A phase II platform study of NIS793 and anti–PD-1 combined with standard of care (SoC) anti-cancer therapy for the second-line (2L) treatment (tx) of microsatellite-stable colorectal cancer (MSS CRC). First Author: Filippo Pietrantonio, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Despite advances in tx of MSS CRC including targeted tx, the prognosis remains poor. The daNIS-3 study (NCT04952753) evaluated efficacy and safety of anti-TGFß monoclonal antibody NIS793 (NIS) and anti-PD1 tislelizumab (TISLE) with SoC as 2L tx for MSS CRC patients (pts). **Methods:** This open-label, multicenter study included safety run-in (SRI) Arm 1a: NIS + SoC (bevacizumab [Bev] + FOLFIRI), Arm 1b: NIS + SoC (Bev + mFOLFOX6) followed by Arm 2a: NIS + TISLE + SoC (Bev + FOLFIRI), Arm 2b: NIS + TISLE+ SoC (Bev + mFOLFOX6) to determine NIS recommended phase 2 dose (RP2D) for expansion phase (EP). FOLFIRI and mFOLFOX6 were evaluated independently. While EP included same investigational arms as SRI (Arm 2b not opened for enrollment), additional SoC arm was added. Primary endpoint was progression-free survival (PFS) in EP; secondary endpoints were PFS for SRI, overall response rate (ORR), disease control rate (DCR), duration of response (DOR) and time to response (TTR) using RECIST V1.1, pharmacokinetics (PK), immunogenicity, safety, and tolerability. Based on data monitoring committee recommendation, study was terminated on 31-07-2023 due to unfavorable benefit-risk profile. **Results:** As of 20-01-2025, median (95% CI) PFS in EP was 5.1 months (mo) (3.6–5.7), 3.7 mo (2.2–5.6), and 7.4 mo (5.5–9.4) for Arms 1a&b, Arm 2a, and SoC, respectively (HR vs SoC [95% CI]: Arms 1a&b, 2.06 [1.34–3.18]; Arm 2a, 1.65 [0.90–3.02]). Secondary endpoints are summarized in Table. PK of NIS and other drugs were similar in EP and SRI. All pts were ADA negative at baseline and during the study. NIS RP2D for Arms 1a&b, and 2a was 2100 mg Q2W. In SRI and EP, overall adverse events (AEs) were comparable across all arms. In EP, grade ≥3 AEs were higher in Arm 1a (67.7%) and 1b (66.7%) compared to Arm 2a (55.2%) and SoC (58.7% & 42.9%). Higher incidence of serious AEs was reported in Arm 1a (49.2%) compared to Arm 2a (31%) and SoC (30.4% & 42.9%). Higher deaths were observed in Arm 1a (50.8%) and 1b (60.0%), mostly attributed to underlying malignancy (MSS CRC). Most common AEs of special interest of NIS were infusion-related reactions, hemorrhage, and skin toxicity, consistent with known safety profile of NIS. **Conclusions:** Overall AEs were comparable, but a higher incidence of grade ≥3 AEs vs SoC were observed. NIS arms showed a deleterious PFS outcome in MSS CRC pts. Clinical trial information: NCT04952753. Research Sponsor: Novartis Pharmaceuticals.

Secondary endpoints*	SRI Arms 1a (N = 13) & 1b (N = 9)	SRI Arms 2a (N = 10) & 2b (N = 8)	EP Arms 1a (N = 67) & 1b (N = 13)	EP Arm 2a (N = 29)	SoC (N = 53)
mPFS, mo (95% CI)	3.6 (1.9, 7.3)	2.1 (1.8, 4.3)	–	–	–

Tislelizumab plus cetuximab and irinotecan in relapsed/refractory RAS/BRAF wild-type and microsatellite stable metastatic colorectal cancer: A randomized, controlled, multicenter study (TEC2). First Author: Xiaojing Xu, Department of Oncology, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Under suboptimal efficacy and safety of current third-line standard-of-care (SoC), several single-arm studies have demonstrated that anti-PD-(L)1 antibodies plus EGFR inhibitors with or without chemotherapy may be valuable for relapsed/refractory *RAS/BRAF* wild-type and microsatellite stable metastatic colorectal cancer (R/R *RAS/BRAF* WT and MSS mCRC). This study aimed to compare tislelizumab (anti-PD-1 antibody) plus cetuximab and irinotecan as third- or later-line therapy versus investigator-selected SoC for R/R *RAS/BRAF* WT and MSS mCRC. **Methods:** This was a randomized controlled, open-label, multicenter study (NCT05278351). Eligible patients were aged ≥18 years with histologically confirmed *RAS/BRAF* WT and MSS metastatic colorectal adenocarcinoma who failed ≥2 prior lines of systemic therapy. Patients were randomly assigned (2:1) to receive intravenous tislelizumab (200 mg) plus cetuximab (500 mg/m^2) and irinotecan (180 mg/m^2) on days 1 and 15 or investigator-selected SoC (fruquintinib, regorafenib, or TAS-102) in a 4-week cycle until disease progression, unacceptable toxicity, or other protocol-defined reasons. Primary end point was progression-free survival (PFS). Secondary end points included objective response rate, disease control rate, duration of response, overall survival, and safety. **Results:** Eighty-seven patients (median age, 62.0 years; 59 [67.8%] men) were enrolled between July 2022 and March 2024, randomized, and assessed for efficacy; one patient did not receive the triplet regimen and was removed from the safety population. With median follow-up of 26.1 months (95% confidence interval [CI]: 22.4-28.4) by data cutoff (June 30, 2025), median PFS was 4.4 months (95% CI, 3.8-6.6) in the tislelizumab-cetuximab-irinotecan group and 2.0 months (95% CI, 1.9-5.4) in the SoC group (Breslow-Gehan *P*=0.009). Landmark analysis at a cutoff point of 10 months showed a significantly extended PFS with tislelizumab plus cetuximab and irinotecan versus SoC (HR 0.37 [95% CI, 0.21-0.64]; p<0.001). Grade ≥3 treatment-related adverse events (TRAEs) occurred at comparable frequencies in the two groups (15.8% *vs* 17.2%). No TRAEs led to death. **Conclusions:** Tislelizumab plus cetuximab and irinotecan as third- or later-line therapy appeared feasible and safe for patients with R/R *RAS/BRAF* WT and MSS mCRC. Clinical trial information: NCT05278351. Association of progression-free survival (PFS) with microsatellite instability–high (MSI-H) or mismatch repair–deficient (dMMR) status determined by single vs dual validated companion diagnostic (CDx) assays: CheckMate-8HW post hoc analyses. First Author: Thierry Andre, Sorbonne Université and Hôpital Saint-Antoine, Assistance Publique Hôpitaux de Paris, Paris, France

Background: First-line (1L) nivolumab (NIVO) + ipilimumab (IPI) showed PFS benefit vs chemotherapy (chemo) in patients (pts) with MSI-H or dMMR metastatic colorectal cancer (mCRC) in the phase 3 CheckMate 8HW trial. Using post hoc analyses, we examined the association of PFS with single and dual positivity in validated CDx MSI (polymerase chain reaction; PCR) or MMR (immunohistochemistry; IHC) central assays. **Methods:** Study details were published previously (Andre T et al. *NEJM* 2024). Pts with unresectable or mCRC with MSI-H or dMMR per local testing were randomized 2:2:1 to NIVO + IPI, NIVO, or chemo. Tumor tissue samples were tested centrally using validated Idylla (CDx MSI PCR; Biocartis) and Dako (CDx MMR IHC; Agilent) assays post randomization. Clinical trial assay positive (CTA+) pts were those with locally diagnosed MSI-H/dMMR mCRC randomized to NIVO + IPI or chemo. PFS and hazard ratios (HR) were evaluated in CTA+ pts; pts positive using a single central assay (CDx MSI or CDx MMR); and pts positive in both central assays (CDx dual positive). **Results:** Of the 303 pts randomized to 1L NIVO + IPI or chemo, 301 had locally diagnosed MSI-H/dMMR (CTA+; 2 randomized pts missed local testing and were excluded in the analysis). 263 pts had valid CDx MSI results, 284 had valid CDx MMR results; 208 were CDx dual positive (Table); result missingness was mainly due to lack of tissue samples. PFS benefit was noted with NIVO + IPI vs chemo in CTA+ pts (HR, 0.32; Table). Greater PFS benefit with NIVO + IPI vs chemo was seen in pts positive with single CDx MSI or CDx MMR assays (HR, 0.20 and 0.22, respectively), and was consistent with those from CDx dual positive pts (HR, 0.20; Table). Pts with microsatellite stable (MSS) or mismatch repair proficient (pMMR) status were low, so these data should be interpreted with caution (Table). **Conclusions:** In this post hoc analysis, dual positivity from CDx MSI and CDx MMR assays did not offer greater PFS benefit with 1L NIVO + IPI vs chemo over positivity from a single CDx MSI or MMR assay. Single CDx MSI or CDx MMR assays provided similar PFS benefit with 1L NIVO + IPI vs chemo in pts with MSI-H/dMMR mCRC. Clinical trial information: NCT04008030. Research Sponsor: Bristol Myers Squibb.

Nivolumab + ipilimumab (NIVO + IPI) vs NIVO in microsatellite instability high/mismatch repair-deficient metastatic colorectal cancer (MSI-H/dMMR mCRC): CheckMate 8HW subgroup analyses including treatment-free status and outcomes in long-term survivors. First Author: Elena Elez, Vall d'Hebron University Hospital and Institute of Oncology (VHIO), Barcelona, Spain

Background: In the phase 3 CheckMate 8HW trial, both dual primary endpoints of progression-free survival (PFS) were met for first-line (1L) NIVO + IPI vs chemotherapy (HR 0.21; $P < 0.0001$) and NIVO + IPI vs NIVO in all lines (HR 0.62; $P = 0.0003$) in patients (pts) with centrally confirmed (CC) MSI-H/dMMR mCRC. We report explorative subgroup analyses of NIVO + IPI vs NIVO. **Methods:** The study design was described previously (Andre *NEJM* 2024). Pts with MSI-H/dMMR mCRC per local testing were enrolled. After randomization, IHC and PCR based tests were used for central confirmation. **Results:** In all randomized pts, 84% (296/354) in the NIVO + IPI and 81% (286/353) in the NIVO arm had CC MSI-H/dMMR; in 1L pts, 85% (171/202) and 85% (170/201) had CC MSI-H/dMMR, respectively. Median follow-up in all randomized pts was 55.1 (range 24.7–68.5) mo. Pts receiving NIVO + IPI had improved disease control rates vs NIVO in 1L (85% vs 81%, respectively) and all lines (84% vs 76%, respectively). Pts with complete or partial response (CR/PR) or stable disease (SD) on 1L NIVO + IPI had improved PFS vs NIVO. In all lines, pts with CR/PR or SD receiving NIVO + IPI had improved overall survival (OS) vs those on NIVO (Table). Pts receiving NIVO + IPI had improved disease-specific OS vs NIVO (HR 0.47; 95% CI 0.32–0.68). In all lines, pts on NIVO + IPI had improved PFS and OS vs NIVO regardless of the number of sites of metastasis (Table). After treatment, 82% (185/226) of pts on NIVO + IPI were alive and treatment free vs 67% (125/186) on NIVO; 90% (198/220) and 79% (141/178) of pts were alive and systemic treatment free, respectively. In pts surviving ≥4 years, baseline characteristics and incidence of treatment-related adverse events were consistent with the all randomized CC population. Further analyses will be presented. **Conclusions:** NIVO + IPI demonstrated clinical benefit vs NIVO across subgroups, as shown by numerically increased PFS and OS in pts with CR/PR or SD, and improved PFS and OS regardless of number of metastatic sites. No defining characteristic was identified in long-term survivors vs all randomized CC pts. These results further support NIVO + IPI as a standard of care treatment for MSI-H/dMMR mCRC. Clinical trial information: NCT04008030. Research Sponsor: Bristol Myers Squibb.

Phase 1 study of the tetravalent death receptor 5 agonist ozekibart (INBRX-109) combined with chemotherapy in locally advanced or metastatic, unresectable colorectal adenocarcinoma (CRC). First Author: Hazel Lote, The Royal Marsden Hospital, London, United Kingdom

Background: Patients with metastatic CRC are typically treated with fluorouracil-based chemotherapy in combination with leucovorin and irinotecan (FOLFIRI) or oxaliplatin (FOLFOX). However, patients who progress after 2 lines of therapy have limited treatment options, with poor outcomes (response rates of ≤6%). Ozekibart (INBRX-109) is a next-generation, tetravalent death receptor 5 agonist that has demonstrated robust efficacy as a single agent in chondrosarcoma. Additionally, ozekibart in combination with FOLFIRI showed early signs of antitumor activity in a small cohort of patients with CRC in the ongoing INBRX-109 phase 1 study (NCT03715933) (Berz D, et al. *J Clin Oncol.* 2025. Abstract 129). Based on these findings, the CRC cohort in this study was expanded to include additional patients who had received 2 or 3 prior lines of systemic therapy. We present initial findings from this cohort. **Methods:** Ozekibart + FOLFIRI was examined in patients with locally advanced or metastatic, unresectable CRC in the expansion cohort C4d of the open-label, INBRX-109 phase 1 study. Eligible patients were aged 18 to < 85 years, had received 2 or 3 prior lines of systemic therapy, and had no chronic or acute liver disease. Previous irinotecan-containing regimens were allowed but not as an immediate prior line of therapy. Patients received ozekibart 3 mg/kg every 4 weeks + FOLFIRI every 2 weeks. Safety and clinical response were primary endpoints. **Results:** As of the data cutoff (October 15, 2025), 44 patients had received ozekibart + FOLFIRI in this cohort. Median age was 54.5 years (range, 29-77 years), and > 70% were in the fourth-line treatment setting; 81.8% had previously received an irinotecan-based regimen. Overall, 28 patients (63.6%) remain on treatment; 11 patients had disease progression, 1 patient discontinued due to adverse events (AEs), and 4 patients discontinued for other reasons. Among evaluable patients for response at data cutoff (n = 26), ozekibart + FOLFIRI led to an ORR of 23% (all partial responses) and a disease control rate of 92%. Consistent with the safety profile of FOLFIRI, the most common AEs (in > 25% of patients) were anemia (any grade, 36.4%; grade ≥3, 9.1%), diarrhea (34.1%; 9.1%), nausea (31.8%; 0%), fatigue (27.3%; 2.3%), and alopecia (27.3%; 0%). Increased alanine aminotransferase was the only grade ≥3 hepatotoxicity event and occurred in 1 patient. **Conclusions:** Ozekibart + FOLFIRI demonstrated encouraging preliminary efficacy in a heavily pretreated patient population with metastatic, unresectable CRC. The safety profile of ozekibart + FOLFIRI was manageable, with most AEs being low grade. Our findings support further evaluation of ozekibart + FOLFIRI in advanced CRC. Updated data will be provided at the time of presentation. Clinical trial information: NCT03715933. Research Sponsor: Inhibrx Biosciences, Inc.

A randomized phase II trial of fruquintinib plus capecitabine versus capecitabine alone as maintenance therapy following first-line chemotherapy in metastatic colorectal cancer (mCRC). First Author: Wenhua Li, Department of Medical Oncology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China

Background: Maintenance therapy with capecitabine (Cap) is widely recommended to unresectable mCRC patients (pts). Fruquintinib (Fru) is a highly selective inhibitor of VEGFR1/2/3. We sought to compare the therapeutic potential of Fru plus Cap versus Cap as maintenance therapy for mCRC. **Methods:** Eligible pts with histologically confirmed mCRC who achieved disease control (including CR/PR and SD) after at least six cycles of first-line standard chemotherapy were included in the study. During phase Ib, pts received Fru (4 mg, p.o. qd, 3 weeks on/1 week off, q4w) plus Cap (850 mg/m^2, p.o. bid, d1-7 and d15-21, q4w). In phase II, pts were randomized in a 1:1 ratio to receive either Fru (RP2D, 3mg, 3 weeks on/1 week off) plus Cap or Cap alone. The primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), disease control rate (DCR) and safety. **Results:** As of November 15, 2025, 113 eligible patients were enrolled, including 6 in phase Ib and 107 in phase II. In this presentation, we report only the updated data from Phase II. 107 were randomly assigned to receive either fruquintinib plus capecitabine (Fru+Cap; n=52) or capecitabine alone (Cap; n=55). Baseline characteristics included median age: 61 years (range, 30-78) vs. 60 years (range, 31-80), male: 51.9% vs. 58.2%, left-sided colorectal primary tumors: 55.8% vs. 61.8% and RAS-mutant tumors: 53.8% vs. 52.7%. As first-line maintenance therapy, the median PFS1 (defined as time from randomization to disease progression or death) in the per-protocol population was 6.03 months with Fru+Cap versus 3.30 months with Cap (p=0.003). Furthermore, the Fru+Cap arm demonstrated significantly prolonged PFS2 (defined as the time from first receipt of first-line treatment to disease progression or death): 12.1 vs. 9.7 months, p=0.006. Consistent improvements were observed in objective response rate (ORR: 14.6% vs. 7.0%) and disease control rate (DCR: 75.6% vs. 51.2%). Grade ≥3 treatment-emergent adverse events (TEAEs) in Fru+Cap arm included hypertension (5.77%), palmar-plantar erythrodysesthesia syndrome (1.9%) and albuminuria (1.9%). Diarrhea (3.64%), palmar-plantar erythrodysesthesia syndrome (1.8%) and oral mucositis (1.8%) were the most frequently reported grade ≥3 TEAEs in Cap arm. **Conclusions:** PFS was significantly prolonged and ORR was improved in mCRC pts treated with Fru plus Cap as first-line maintenance treatment. The safety profile of the combination regimen was manageable and aligned with the expected toxicity patterns of the individual agents. Clinical trial information: NCT05451719. Research Sponsor: None.

Intravenous oncolytic virus IDOV-Safe in pMMR/MSS metastatic colorectal cancer. First Author: Tong Xie, Gastrointestinal Cancers, Beijing Key Laboratory of Cell & Gene Therapy for Solid Tumor, State Key Laboratory of Holistic Integrative Management of Gastrointestinal Cancers, Department of GI Oncology, Peking University Cancer Hospital & Institute, Beijing, China

Background: Proficient mismatch repair/microsatellite stable (pMMR/MSS) metastatic colorectal cancer (mCRC) is largely resistant to immune checkpoint inhibitors, with limited options after standard therapies. IDOV-Safe is a systemically deliverable, vaccinia virus-based oncolytic virotherapy. This phase 1 clinical trial evaluated the safety and preliminary efficacy of intravenous IDOV-Safe combined with toripalimab and fruquintinib in patients with pMMR/MSS mCRC (NCT06380309). **Methods:** Patients with pMMR/MSS mCRC who had progressed on or were intolerant to ≥2 prior systemic therapies were enrolled. Dose escalation used a 3+3 design across four dose levels (1×10^9, 3×10^9, 1×10^{10}, and 3×10^{10} PFU). In expansion, three combination strategies with immune-target therapy were evaluated: sequential, early, and IO free combinations using fruquintinib with or without toripalimab. Primary endpoints were safety and objective response rate (ORR). **Results:** Fifty-five patients were enrolled; 80% had received ≥3 prior treatment lines. Dose-limiting toxicities at 1×10^{10} PFU led to selection of 1×10^9 and 3×10^9 PFU for expansion. Grade ≥3 treatment-related adverse events (TRAEs) occurred in 62% of patients, most commonly fever, thrombocytopenia, and neutropenia; grade ≥3 immune-related events were infrequent (2%), and no grade ≥3 TRAEs were attributed to fruquintinib. In sequential combination cohorts, objective responses occurred only after initiation of combination therapy. ORR was 33.3% at 1×10^9 PFU (IIA1) and 30.0% at 3×10^9 PFU (IIA2), with disease control rates (DCRs) of 50.0% and 70.0%, respectively. In early combination cohorts, objective responses were observed at 3×10^9 PFU (IIC2; ORR 16.7%), with high DCRs (83.3% in IIC1 and 91.7% in IIC2). The DCR in the IO-free cohort (IID) was 50.0%. Median progression-free survival (mPFS) across five cohorts was 5.4 (IIA1), 8.7 (IIA2), 5.4 (IIC1), 5.5 (IIC2), and 4.6 months (IID). **Conclusions:** Intravenous IDOV-Safe demonstrated a favorable safety profile and encouraging preliminary antitumor activity when combined with toripalimab and fruquintinib, particularly using a sequential combination strategy in heavily pretreated patients with pMMR/MSS mCRC. Clinical trial information: NCT06380309. Research Sponsor: None.

Efficacy and safety of cetuximab-irinotecan rechallenge versus regorafenib in *RAS* wild-type metastatic colorectal cancer. First Author: Hao Chen, Fujian Medical University Union Hospital, Fuzhou, China

Background: Anti-epidermal growth factor receptor (EGFR) antibodies are widely used in the treatment of RAS wild-type metastatic colorectal cancer (mCRC) across various lines of therapy, including after disease progression. **Methods:** A single-center, prospective, randomized controlled trial (ChiCTR1900026961) evaluated the efficacy of cetuximab rechallenge in mCRC patients with RAS wild-type tumors who had initially responded to cetuximab-based therapy but subsequently progressed on a cetuximab-free regimen. The trial compared cetuximab plus irinotecan with regorafenib, with progression-free survival (PFS) as the primary endpoint and overall survival (OS), disease control rate (DCR), objective response rate (ORR), and safety as secondary endpoints. **Results:** Among 68 patients with microsatellite-stable (MSS), RAS wild-type tumors, 35 received cetuximab rechallenge therapy and 33 received regorafenib. The cetuximab group achieved a DCR of 68.6% and an ORR of 8.6%, both significantly higher than those observed in the regorafenib group. Median PFS was 5.5 months in the rechallenge group compared with 2.6 months in the regorafenib group, while median OS was 18.8 months versus 10.4 months, respectively. Adverse events in the cetuximab group were predominantly grade 1–2 and manageable with supportive care. Univariate and multivariate Cox regression analyses identified age, ECOG performance status, and washout period duration as independent prognostic factors. A nomogram was developed to predict the efficacy of cetuximab rechallenge therapy. **Conclusions:** These findings suggest that cetuximab rechallenge offers promising clinical activity with acceptable toxicity in RAS/BRAF wild-type mCRC, supporting further investigation of rechallenge strategies and biomarker-guided approaches to optimize outcomes in advanced CRC. Clinical trial information: ChiCTR1900026961. Research Sponsor: Tthe Joint Funds for the Innovation of Science and Technology of Fujian province (2018Y9032).

Zongertinib in HER2-altered colorectal cancer: A pooled analysis of colorectal cancer patients from two clinical trials. First Author: Dirk Arnold, Asklepios Tumorzentrum Hamburg, AK Altona, Hamburg, Germany

Background: Zongertinib, an irreversible TKI, selectively inhibits HER2 while sparing wild-type EGFR, thereby minimizing associated toxicities. Here, we present a pooled analysis of a subgroup of patients (pts) with HER2-positive colorectal cancer (CRC) who received zongertinib monotherapy in Phase Ia of a dose-escalation/expansion trial (NCT04886804) or in the ongoing Phase II Beamion PANTUMOR-1 trial (NCT06581432), as well as supporting preclinical data. **Methods:** Preclinical antitumor activity of zongertinib as monotherapy or in combination with other HER2-directed agents was assessed in commercially available *HER2*-amplified mouse PDX models of CRC. Phase Ia of NCT04886804 enrolled pts with advanced solid tumors and HER2 alterations (mutations, amplification, or overexpression) who had exhausted all other standard treatment options. Beamion PANTUMOR-1 includes pts with previously treated HER2-positive (amplification or overexpression) or *HER2*-mutant solid tumors. Pts in NCT04886804 received escalating doses of zongertinib (15 mg BID or 180–360 mg QD); pts in Beamion PANTUMOR-1 received zongertinib 120 mg QD. Efficacy (investigator-assessed objective response rate [ORR]; RECIST v1.1) and safety (incidence of adverse events [AEs]; CTCAE v5.0) were assessed. **Results:** In *HER2*-amplified PDX CRC models, zongertinib monotherapy and in combination with other HER2-directed agents led to tumor growth inhibition or regression, with greater antitumor activity observed with the combinations. A total of 20 pts with HER2-positive CRC (10 from each trial) received zongertinib. Pts had a median age of 53 years (range: 36–70) and had received a median of 2.5 lines of prior systemic therapy. A total of 8 pts (6 from NCT04886804 and 2 from Beamion PANTUMOR-1) had received ≥1 prior HER2-directed therapy, including trastuzumab, pertuzumab, or T-DXd. Median treatment duration with zongertinib was 5.1 months (range: 0–18). The confirmed ORR was 45% (n = 9; all partial responses). A further 9 (45%) pts achieved stable disease, giving a disease control rate of 90%. At the time of analysis, 7 (35%) pts remained on treatment. Treatment-related AEs (TRAEs, any grade/grade ≥3) were reported in 70%/5% of pts. The most common TRAEs were diarrhea (9 pts [45%], all grade 1), rash (3 pts [15%], all grade 1), anemia (2 pts [10%], all grade 2), and increased AST (2 pts [10%], all grade 2). Only one pt had a grade ≥3 TRAE (grade 3 increased lipase). No grade 4 or 5 AEs were reported. **Conclusions:** Pooled analysis of HER2-positive CRC pts from two clinical trials indicates that zongertinib monotherapy has encouraging clinical activity and manageable safety in pts with advanced, HER2-positive CRC, supported by PDX models. Based on these findings, zongertinib continues to be developed in CRC, with Beamion PANTUMOR-1 actively enrolling. An additional Phase Ib/II trial (Beamion BCGC-1, NCT06324357) is also underway. Clinical trial information: NCT04886804, NCT06581432. Research Sponsor: Boehringer Ingelheim.

First-line immune checkpoint inhibitors in elderly colorectal cancer patients in the real world: Retrospective phase of the multicenter ELDER CRC trial. First Author: Martina Cassaniti, Oncology Unit, University Hospital of Ferrara, Ferrara; Oncology Unit Santa Maria delle Croci Hospital - AUSL Romagna, Ravenna, Italy

Background: dMMR/MSI-H metastatic colorectal cancer (mCRC) is more common among the elderly. However, insufficient data about their treatment with immune checkpoint inhibitors (ICIs) are available from interventional and observational trials. **Methods:** ELDER CRC is an observational, multicenter Italian trial enrolling elderly (≥70 years [yrs]) patients (pts) treated with first-line ICI(s) for dMMR/MSI-H mCRC in the real world. Results from the retrospective cohort are presented. **Results:** 132 pts aged 77 yrs as median (IQR 74-82, range 70-93; <75: 32.6%; 75-79: 29.5%; ≥80: 37.9%) were enrolled across 10 Centers. They were mainly female (56.1%) in mediocre conditions (ECOG PS 1: 51.9%, ≥2: 22.2%; G8 ≤14: 80.5% [33/41 available]) with BRAF mutated (58.9% [73/124]), right primary tumor (80%), and synchronous metastases (54.5%) involving liver (34.8%) and/or peritoneum (37.9%). Almost all pts received monotherapy (pembrolizumab or nivolumab: 98.5%; nivolumab+ipilimumab: 1.5%) and most discontinued for PD (31.1%) or completion of 2 yrs (13.6%). 65.2% had an adverse event (AE), mainly fatigue (37.9%), skin rash (20.5%), hypothyroidism (17.4%), diarrhea (15.9%), and arthralgia (12.9%). Only 11% had G3-4 AE (G5=0), mainly gastrointestinal (3.8%), lung (3%), and fatigue (2.3%) and 10.6% discontinued ICI for AE. On 122 evaluable pts, ORR was 51.6% (38.5% PR + 13.1% CR) with 26.2% SD and 22.1% primary PD. At median follow-up of 25.9 months [mos] (22.3-30.3), mPFS was 32.2 mos (26.2-NE) with 56 events and mOS 45.8 mos (32.2-NE) with 46 events. 28.8% are still on treatment at the time of this analysis. Survival outcomes were not influenced by age groups. G8 >14 was related with better PFS (HR=0.79, *p*=0.06) and OS (HR=0.89, *p*=0.09). At multivariable model only neutrophils/lymphocytes ratio ≥3 was significantly associated with worse PFS (HR=1.91, *p*=0.03), while no variables with OS. **Conclusions:** Our results confirm the benefit of first-line immunotherapy for dMMR/MSI-H mCRC even among elderly pts treated in the real world, despite the substantial rate of right-sided and/or BRAF mut CRC pts and regardless of age group. The manageable safety profile of ICI(s) was also confirmed. G8 might be predictive of outcome but needs implementation in daily practice. Research Sponsor: None.

Overall survival benefit of doublet versus triplet BRAF inhibitor–based therapy: Insights from the BEETS study (JACCRO CC-18). First Author: Chiaki Inagaki, Department of Medical Oncology, Kindai University Faculty of Medicine, Sakai, Osaka, Japan

Background: Cetuximab plus encorafenib, with or without binimetinib, is established as one of the standard treatment options for *BRAF* V600E-mutated metastatic colorectal cancer (mCRC) in the second- or later-line setting. Although the triplet therapy (encorafenib/cetuximab/binimetinib; T) is approved in Japan and commonly used for patients with poor prognostic features based on guideline recommendations, objective biomarkers to guide optimal patient selection remain lacking. Given the BREAKWATER trial support for first-line doublet therapy (encorafenib/cetuximab; D) with chemotherapy, the clinical role of MEK inhibitor–containing regimens may become more limited; nevertheless, the development of biomarkers capable of identifying patients who are likely to benefit from MEK inhibition remains an important unmet need. We therefore performed a prospective translational analysis within the BEETS study to identify biomarkers that guide treatment selection between T and D. **Methods:** BEETS (JACCRO CC-18: UMIN000045530) was a multicenter, prospective biomarker study of second/third-line encorafenib-based D or T regimen. We prospectively collected paired pre- and post-treatment blood samples, and analyzed pre-treatment tumor-educated platelet RNA by RNA sequencing (TEP-seq). To address baseline imbalances, propensity score matching (PSM) was performed using ECOG PS, number of metastatic organs (≥3), C-reactive protein (>1 mg/dL), and prior primary tumor resection. Interaction between gene expression (z-score) and treatment arm was evaluated using Cox proportional hazards models. Candidate biomarkers were prioritized based on $|\log2(HR)| \geq 0.5$ and $P < 0.05$. **Results:** Of 203 enrolled patients, 189 were evaluable for TEP-seq. After PSM, 81 patients per arm were analyzed. In the matched cohort, median overall survival (OS) was longer for D than T (17.4 months [m] vs. 10.2 m, HR 1.80; 95% CI:1.24–2.61). Interaction screening identified 44 genes for which higher expression was associated with better outcomes on D but worse outcomes on T, and six genes showing the opposite pattern. Among these candidates, *RAD51C* expression emerged as a representative marker; when dichotomized at the arm-specific median, higher expression favored T but indicated worse outcomes with D (*RAD51C* Low vs. High; T 7.8m vs. 10.6m, HR 0.79, 95%CI 0.49–1.28; D 28.2m vs. 12.9m, HR 2.02, 95%CI 1.16–3.53). Pathway-level exploration suggested a possible association between elevated *RAD51C* expression and increased MAPK-related signaling activity, potentially explaining the requirement for more intensive MEK inhibition in these patients. **Conclusions:** While OS was superior with D regimen in this matched cohort, *RAD51C* expression was identified as a candidate biomarker for identifying patients who may derive preferential benefit from MEK inhibition. Clinical trial information: UMIN000045530. Research Sponsor: None.

Ultra–early-onset metastatic colorectal cancer (<35 years): RAS-driven, APC/TP53-depleted, TMB-low molecular features in a real-world analysis of 2,392 patients. First Author: Andrea Pretta, Medical Oncology Unit, University Hospital and University of Cagliari, Cagliari, Italy

Background: Early-onset colorectal cancer (CRC, <50 years) is on the rise globally and includes a biologically heterogeneous disease. Patients diagnosed before age 35 represent the extreme of early-onset CRC, yet their clinical and genomic features remain poorly understood. We investigated whether ultra–early-onset metastatic CRC (UEO-CRC, <35 years) exhibits distinct outcomes and a unique molecular profile in a large real-world cohort. **Methods:** We analyzed a multicenter cohort of 2,392 patients with metastatic CRC; 1,612 had comprehensive genomic profiling (Foundation Medicine) and were included in molecular analyses. Patients were classified as ≤35 years (n=130) or >35 years (n=1482) at metastatic diagnosis. Overall survival (OS) was assessed using Kaplan–Meier estimates and log-rank tests. Gene- and pathway-level differences were evaluated using Fisher's exact test. A composite UEO-CRC molecular signature was defined based on features significantly enriched or depleted in patients <35 years. **Results:** UEO-CRC represented 8.1% of metastatic cases. Patients ≤35 years had significantly worse survival than those >35 years (median OS 35.0 vs 46.0 months; p=0.0081). Molecular profiling revealed a distinct oncogenic pattern characterized by: enrichment of RAS mutations (KRAS 48.6% vs 36.4%, p=0.011; NRAS 11.7% vs 4.1%, p=0.0011); marked depletion of APC (21.6% vs 63.4%, p<0.001) and TP53 mutations (33.3% vs 63.8%, p<0.001); suppression of WNT pathway alterations (25.2% vs 66.9%, p<0.001); and genomic stability without hypermutation, including absence of TMB-high tumors (0% vs 7.5%, p=0.00037), lower median TMB (3.1 vs 4.8 mut/Mb, p<0.001), no MSI-H cases, and rare POLE/POLD1 or DDR alterations (4.5% vs 1.2%, p=0.017). Integration of these features identified a reproducible UEO-CRC molecular signature (RAS-mutant, APC/TP53 wild-type, TMB-low), over six-fold more frequent in UEO-CRC than in patients ≥35 years (32% vs 5%; p<0.001). **Conclusions:** Ultra–early-onset metastatic CRC (<35 years) represents a biologically aggressive and genomically distinct entity. UEO-CRC is defined by a non-canonical, RAS-driven, APC/TP53-independent tumorigenic program occurring without hypermutation, MSI-H, or POLE-driven biology. The lack of TMB-high indicates limited immunogenicity, emphasising the need for age-specific biological stratification and customised therapeutic strategies in this high-risk population. Research Sponsor: None.

Survival outcomes of human epidermal growth factor receptor 2 (HER2)–amplified and HER2-mutated left-sided colorectal cancer (CRC) patients treated with anti-epidermal growth factor receptor (EGFR) monoclonal antibodies (mAbs). First Author: Yu Jen Alexander Jan, Division of Hematology-Oncology, Department of Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Current guidelines support the use of anti-EGFR mAbs in left-sided CRCs without mutations in *KRAS*, *NRAS* and *BRAF*. Recent reports indicated that HER2-amplified CRCs might respond worse to anti-EGFR mAbs, whereas HER2-mutated CRCs and their response to anti-EGFR mAbs remained relatively unexplored. In this study, we assembled the largest collection of HER2-altered (amplified or mutated) CRCs to date from a real-world database with the goal of describing the impact of these alterations on anti-EGFR mAb therapy. **Methods:** Patients profiled by Caris Life Sciences with microsatellite stable, left-sided CRC without mutations in *KRAS*/*NRAS*/*BRAF* who received anti-EGFR mAbs (cetuximab or panitumumab) were included in this study. Microsatellite stability, amplifications (copies ≥6), and pathogenic or likely pathogenic mutations were identified by NGS. Patient outcomes were obtained from insurance claims data. Overall survival (OS) was calculated from start of anti-EGFR mAbs to time of last clinical contact. Time on treatment (ToT) was calculated from start to end of anti-EGFR mAbs. Hazard ratios and p-values were calculated using the Cox proportional hazards model and log-rank test. **Results:** A total of 3217 patients were included for analysis. Patients were stratified into 3 cohorts: HER2-amplified (N=114), HER2-mutated (N=46), and HER2-normal (N=3057). The HER2-mutated group was older than the HER2-amplified and the HER2-normal groups (median: 64.5 vs 56 and 58 years, p=0.006); no other significant differences were found in patient demographics. The HER2-mutated group had worse OS and ToT than the HER2-normal group (median OS 12.4 vs 25.9 months, HR 1.57, p=0.013; median ToT 4.3 vs 6.7 months, HR 1.40, p=0.036). The HER2-amplified group showed no significant differences in OS but worse ToT compared to the HER2-normal group (median OS 26.1 vs 25.9 months, HR 0.98, p=0.856; median ToT 5.8 vs 6.7 months, HR 1.25, p=0.035). In multivariate Cox regressions accounting for age, gender, and receipt of HER2-targeted therapy, the HER2-mutated group had worse OS and ToT compared to HER2-normal group (OS HR 1.66, p=0.007; ToT HR 1.55, p=0.007), while the HER2-amplified group showed no significant differences in OS and ToT compared to HER2-normal group (OS HR 1.14, p=0.398; ToT HR 1.26, p=0.073). **Conclusions:** In this large, real-world cohort of *KRAS*/*NRAS*/*BRAF* wild-type, left-sided CRCs receiving anti-EGFR mAbs, HER2-mutated patients had worse ToT and OS than HER2-normal patients, whereas HER2-amplified patients showed no difference in OS compared to HER2-normal patients. These findings suggest that alternative treatment studies should be explored in HER2-mutated left-sided CRCs, underscoring the importance of additional biomarker-directed studies in this patient cohort. A phase Ib, open-label, clinical trial of JAB21822 combined with second-line chemotherapy for metastatic colorectal cancer with *KRAS* G12C mutation. First Author: Zhenghang Wang, Department of Gastrointestinal Oncology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital and Institute, Beijing, China

Background: Glecirasib (JAB-21822), a novel, covalent, small molecule KRAS G12C-GDP covalent inhibitor, has been shown to be effective and safe as monotherapy or in combination with cetuximab in treating patients with refractory, unresectable locally advanced or metastatic colorectal cancer (mCRC) harboring KRAS G12C mutation. There are few data regarding the efficacy and safety of KRAS G12C inhibitor in the second-line setting. This multicenter, phase Ib, open label, single arm study aims to investigate the efficacy and safety of glecirasib in combination with the standard second-line chemotherapy and bevacizumab in patients with mCRC with KRAS G12C mutation who failed first-line treatment (NCT06838338). **Methods:** Patients (pts) with mCRC harboring KRAS G12C mutation were enrolled and treated with glecirasib (800mg QD) combined with standard second-line chemotherapy (FOLFIRI or FOLFOX) and bevacizumab until disease progression or intolerable toxicity or patient-initiated withdrawal from the study. The primary endpoint was confirmed objective response rate (ORR). The secondary endpoints included overall survival (OS), progression-free survival (PFS), disease control rate (DCR), duration of response (DoR) and safety. **Results:** As of Dec 10, 2025, 26 pts were enrolled and received glecirasib combined with chemotherapy and bevacizumab in four centers. The median age was 58 years with female (54%)/male (46%), ECOG 0 (8%)/1 (92%). A total of 20 subjects had at least one post-baseline tumor assessment. The confirmed ORR and DCR were 50% (10/20) and 100% (10/20), respectively. Median DoR was 10.1 months (95%CI: 2.9, NE), median PFS was 11.5 months (95%CI: 5.5, NE). Any grade treatment-related adverse events (TRAEs) occurred in 23/26 (88.5%) pts, the most common ones (>20%) being diarrhea, nausea and anemia. Grade 3-4 TRAEs occurred in 6 (23.1%) pts. No grade 5 TRAEs occurred. **Conclusions:** Glecirasib in combination with the second-line standard chemotherapy and bevacizumab demonstrated encouraging efficacy and tolerable safety in the second-line treatment of mCRC patients with KRAS G12C mutation. Clinical trial information: NCT06838338. Research Sponsor: None.

3545 **Poster Session**

A prospective randomized controlled trial of FAPI PET/CT-guided radiotherapy combined with second-line standard systemic treatment and cadonilimab versus second-line standard systemic treatment alone in patients with peritoneal metastasis from colorectal cancer (TORCH-PM01). First Author: Juefeng Wan, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: This study evaluates the efficacy and safety of FAPI PET/CT-guided radiotherapy combined with second-line systemic treatment and cadonilimab compared to second-line systemic treatment alone in patients with peritoneal metastasis from colorectal cancer. **Methods:** In this prospective randomized controlled trial, we enrolled patients with peritoneal metastasis from colorectal cancer who progressed after first-line systemic therapy. Patients were randomly assigned to the control group, receiving second-line standard systemic treatment (n = 20), or the study group, which received hyopfractionated radiotherapy (20-25 Gy in 5 fractions) combined with second-line systemic treatment and cadonilimab (n = 20). The primary endpoint was overall response rate (ORR). A total of 40 patients were enrolled, with 19 evaluable patients in each group following loss to follow-up. **Results:** The ORR was significantly higher in the study group at 63.2% (12/19) compared to 15.8% (3/19) in the control group (p = 0.003). Adverse events (AEs) of grade 3-4 in the study group included neutropenia (26.3%, 5/19), nausea (15.8%, 3/19), vomiting (15.8%, 3/19), and diarrhea (15.8%, 3/19). In the control group, the most common grade 3-4 AE was neutropenia (21.1%, 4/19) and vomiting (10.5%, 2/19). Immune-related AEs of grades 1-2 in the study group included skin reactions (15.8%, 3/19), hypothyroidism (5.3%, 1/19), hepatitis (5.3%, 1/19), and myocarditis (15.8%, 3/19). One case of grade 3-4 skin reaction (5.3%) was observed in the study group. **Conclusions:** FAPI PET/CT-guided radiotherapy combined with second-line systemic treatment and cadonilimab significantly improves ORR in patients with peritoneal metastasis from colorectal cancer compared to standard second-line treatment alone, with manageable toxicity profiles. These findings support a promising therapeutic strategy for this challenging patient population. Clinical trial information: NCT07079462. Research Sponsor: None.

3546 **Poster Session**

A multicenter single-arm phase II trial evaluating the safety and efficacy of panitumumab and irinotecan in patients with Neo*RAS* wild-type metastatic colorectal cancer (C-PROWESS trial). First Author: Hiroki Osumi, Kanagawa Cancer Center, Department of Gastroenterology, Yokohama, Japan

Background: Previous studies have demonstrated favorable efficacy of anti-epidermal growth factor receptor (EGFR) monoclonal antibody (mAb) in metastatic colorectal (mCRC) patients with Neo*RAS* wild type (WT), ie, conversion of *RAS* status from mutant to WT following treatment. This multicenter, single-arm, phase II trial evaluated the efficacy and safety of panitumumab plus irinotecan for mCRC patients with Neo*RAS* WT. **Methods:** Patients with tissue-confirmed *RAS* mutant mCRC who developed intolerance to or disease progression after fluoropyrimidine, oxaliplatin, and irinotecan were screened for *RAS* mutation status in circulating tumor DNA (ctDNA) with the OncoBEAM RAS CRC assay. Those without *RAS* mutations detected within 28 days before enrollment received panitumumab (6 mg/kg) and irinotecan (150 mg/m^2) biweekly. The primary endpoint was a response rate (RR) per RECIST 1.1. Secondary endpoints included disease control rate (DCR; response or stable disease), progression-free survival (PFS), overall survival (OS), safety, and biomarker analysis using next-generation sequencing (NGS) of ctDNA (Guardant360). The null hypothesis was a RR of $< 4\%$, and the alternative hypothesis was $\geq 15\%$, with 80% power and a one-sided 10% significance level. The required sample size is 30. **Results:** Among 404 patients screened for *RAS* status in ctDNA, conversion to Neo*RAS* WT was observed in 54 (13.3%), and 30 patients were enrolled. Median age was 66.5 years old, and 20 (66.7%) were male. Lung was the most frequent site of metastasis (73.3%), and *KRAS* exon 2 accounted for 80% of prior tissue *RAS* MT. RR and DCR were 6.7% (80% CI, 1.8 to 16.8) and 76.7% (95% CI, 57.7 to 90.1), respectively. With median follow-up 22.4 months, median PFS was 4.1 months and median OS was 16.8 months. Grade 3 adverse events were observed in 14 patients (46.7%): skin toxicity (13.3%), hypomagnesemia (10.0%), diarrhea (10.0%), appetite loss (10.0%), and anemia (7.0%). No grade $\geq$4 adverse event was observed. ctDNA NGS results were available for 27 patients and included *KRAS* (44.4%), *NRAS* (3.7%), and *PIK3CA* (7.4%) mutations and *ERBB2* amplification (3.7%). RR for patients with none of these mutations (negative hyper-selection cohort) was 16.7% (2/12) while no patient with any of these alterations achieved a response (0/15). Negative hyper-selection was associated with significantly longer PFS and OS (PFS: 6.1 vs 2.9 months, HR, 0.37, 95% CI, 0.16 to 0.87; OS: 25.5 vs 13.1 months, HR, 0.34, 95% CI, 0.12 to 0.99). In multivariate analysis, negative hyper-selection was an independent factor for PFS (HR, 0.12, 95%CI, 0.03 to 0.41) and OS (HR, 0.30, 95%CI, 0.10 to 0.96). **Conclusions:** Anti-EGFR mAb with chemotherapy may be effective for Neo*RAS* WT mCRC, especially for patients hyper-selected for absence of gene mutations related to anti-EGFR mAb resistance. Clinical trial information: s031210565. Research Sponsor: None.

Serum VEGF-A concentrations as a predictive biomarker of immunotherapy response in refractory metastatic colorectal cancer (mCRC): An exploratory analysis of CCTG CO.26. First Author: François Jobin Gervais, Princess Margaret Cancer Centre-University Health Network, Toronto, ON, Canada

Background: Benefits of immune checkpoint inhibitors (ICIs) in unselected proficient mismatch repair (pMMR) mCRC remain unestablished. This exploratory analysis of CCTG CO.26 evaluated whether serum VEGF-A concentrations may influence ICI efficacy. **Methods:** CCTG CO.26 was a phase II trial that randomized refractory mCRC patients (pts) (2:1) to Durvalumab + Tremelimumab + Best supportive care (DT) vs Best supportive care (BSC) alone and was positive for overall survival (OS). VEGF-A concentrations were determined in baseline serum samples using an ELISA method. OS and progression-free survival (PFS) were compared between high and low groups based on median VEGF-A concentration in each treatment arm. An optimal cutoff was also identified using a minimal p-value approach. *VEGFA* mRNA expression from tissue-based RNA-seq was analyzed in the INSPIRE study, a separate, single arm, multicohort phase II trial comprising multiple tumor types treated with pembrolizumab for external validation. **Results:** Baseline VEGF-A concentrations were available for 161 pts (47 BSC, 114 DT). Median VEGF-A concentration was 1166 pg/ml (range: 226 – 4898; IQR: 784-1755). VEGF-A concentrations were significantly higher in ECOG 1 vs 0 pts (p = 0.03), and in pts who had previously received regorafenib (p = 0.03). Grouped by median VEGF-A, median OS was longer in DT-treated patients with low VEGF-A (7.39 months for DT-Low vs. 6.08 DT-high; hazard ratio (HR) 0.62, 95% confidence interval (CI): [0.42–0.90], p = 0.01), but not in BSC treated patients (4.44 months BSC-Low vs. 4.11 BSC-High; HR 1.05 [0.57–1.92], p = 0.88; interaction HR 0.56 [0.28–1.14], p = 0.11). An optimal VEGF-A threshold of 1540 pg/mL was identified using a minimal p-value approach, with 33.5% pts having high VEGF-A concentrations. Median OS was 7.29 vs 4.37 months for DT-Low and DT-High pts (HR 0.53 [0.35–0.80], $p < 0.005$), and 3.55 vs 7.46 months for BSC-Low and BSC-High pts (HR 1.50 [0.80–2.80], p = 0.21; interaction HR 0.33, [0.16–0.70], $p < 0.005$). In multivariable analyses incorporating ECOG, presence of liver metastases, plasma tumor mutation burden and arginine levels, low VEGF-A concentrations remained statistically associated with improved OS with DT (HR 0.46 [0.30–0.70], $p < 0.001$; interaction HR 0.18 [0.083–0.41], $p < 0.0001$). There was no association between VEGF-A concentrations and PFS in any arm. In the INSPIRE study (n = 66), *VEGFA* mRNA expression was lower in responders ($p < 0.001$) and significantly associated with improved PFS (HR 0.45 [0.25–0.79], p = 0.006) and OS (HR 0.47 [0.26–0.85], p = 0.013) across tumor types. **Conclusions:** Refractory mCRC patients with low VEGF-A concentrations may derive benefit from ICIs. This is the first report to suggest that serum VEGF-A concentration is a potential predictive biomarker for benefit from ICIs. These findings should be prospectively validated. Research Sponsor: None.

3548 Poster Session

Antitumor activity of amivantamab by consensus molecular subtypes in *RAS/BRAF* wild-type metastatic colorectal cancer: Secondary analyses from the phase 1b/2 OrigAMI-1 study. First Author: Marcia Roxana Cruz-Correa, University of Puerto Rico and Pan American Center for Oncology Trials, San Juan, Puerto Rico

Background: Colorectal tumors are classified by mutational subtypes and sidedness, which inform treatment and outcomes. They can also be classified into four Consensus Molecular Subtypes (CMS1–4), with CMS2 (*EGFR*-dependent, canonical) typically showing better prognosis and CMS4 (*EGFR*-independent, MET pathway associated, mesenchymal) associated with poor prognosis and limited response to traditional EGFR inhibition (Thanki *Int Biol Biomed J* 2017, Woolston *Cancer Cell* 2019). In prior analyses, cetuximab monotherapy demonstrated greater antitumor activity against CMS2 *RAS* wild-type (WT) vs CMS4 *RAS* WT tumors (disease control rate [DCR]: 68% vs 29%; Chowdhury *JCO Precis Oncol* 2023), suggesting CMS4 may limit cetuximab efficacy de novo. Additionally, CMS2 to CMS4 subtype switching has been described as a cetuximab monotherapy resistance mechanism (Woolston *Cancer Cell* 2019). Amivantamab, an EGFR–MET bispecific antibody approved for *EGFR*-mutated NSCLC, has demonstrated antitumor activity in refractory metastatic colorectal cancer (mCRC), independent of sidedness. Given the role of *MET* in mesenchymal subtypes (CMS4), targeting with amivantamab could demonstrate antitumor activity in both CMS2 and CMS4. **Methods:** OrigAMI-1 (NCT05379595) enrolled participants with mCRC harboring WT *KRAS*, *NRAS*, *BRAF*, and *EGFR* ectodomain and without *ERBB2/HER2* amplification. Participants with left-sided mCRC without (Cohort A) or with prior anti-EGFR therapy (Cohort B), and those with right-sided disease (Cohort C), received intravenous amivantamab monotherapy. All enrolled participants had 2–3 prior lines of therapy in the metastatic setting. CMS assignment and expression changes in key EGFR/MET ligands at baseline (n = 76) and Cycle 3 Day 1 (C3D1; n = 17) were analyzed by whole-transcriptome RNA-sequencing of biopsies. **Results:** CMS2 (canonical) and CMS4 (mesenchymal) comprised ~95% of tumors. Clinical outcomes for CMS2 (n = 42) and CMS4 (n = 31) were comparable: median PFS was 4.2 vs 5.3 months (P =0.5), respectively, and median OS was 11.3 vs 13.5 months (P= 0.6). PFS and OS within CMS2 and CMS4 subgroups remained consistent across sidedness. Overall response rate and DCR were comparable between CMS2 and CMS4 (26% vs 16% and 83% vs 74%, respectively). Genomic profiles derived from ctDNA were similar for CMS2 and CMS4; however, baseline *AREG/EREG* mRNA expression was higher in CMS2. Paired biopsies demonstrated antitumor activity with or without subtype switching at C3D1. Amivantamab treatment generally decreased *AREG/EREG* and increased *HGF* expression, independent of subtype or response. **Conclusions:** Amivantamab monotherapy demonstrated consistent antitumor activity in both canonical, *EGFR*-dependent (CMS2) and mesenchymal, *EGFR*-independent (CMS4) tumors unlike traditional EGFR inhibitors in refractory *RAS/BRAF* WT mCRC. Clinical trial information: NCT05379595. Research Sponsor: Janssen Research & Development, LLC, a Johnson & Johnson company.

3549 Poster Session

First-in-human study of cavitation-enhanced drug delivery (CEeDD) by sonosensitive particles and focused ultrasound applied to colorectal metastases in the liver. First Author: Jeffrey Rubasingham, Oxford University, Oxford, United Kingdom

Background: Effective treatment of colorectal liver metastases is limited by poor drug delivery, particularly for monoclonal antibodies, the large molecular weight of which, together with abnormal tumor vasculature, elevated interstitial pressure and dense stromal architecture, restricts penetration and distribution into solid tumors. This first-in-human study evaluated a novel platform combining intravenously infused sub-micron gas-stabilizing sonosensitive particles with novel handheld ultrasound probe to cause cavitation that enhances the transport of systemically co-administered therapeutics (i.e. cetuximab/irinotecan) from the vasculature into tumors, without the need to modify these therapeutics. **Methods:** The study comprised 3 patient cohorts. Cohort 1 evaluated the safety of ultrasound activation of intravenously infused sonosensitive particles alone, without drug. With safety confirmed, Cohort 2 assessed intratumoural drug concentration in patients undergoing surgical resection after receiving subtherapeutic irinotecan and cetuximab, with or without ultrasound-activated particles. Cohort 3 evaluated early efficacy in patients receiving standard of care FOLFIRI and cetuximab, with or without cavitation in repeated treatment cycles. Primary endpoints were grade 3 or higher adverse events in Cohort 1, intratumoural drug concentrations in Cohort 2, and radiological tumor response in Cohort 3. **Results:** In Cohort 2, seven evaluable patients underwent resection, with 4 in the control arm and 3 in the ultrasound-mediated-cavitation arm. Mean cetuximab concentrations were modestly higher in the tumour centre (3.6 vs 3.2 ng/mL) and mid radius (4.1 vs 3.7 ng/mL), and substantially higher at the tumour periphery (7.1 vs 3.7 ng/mL) in the ultrasound-mediated-cavitation arm, while liver margin levels were comparable. There was no appreciable beneficial difference in the mean tumour concentrations of irinotecan and its metabolites between the two arms. In Cohort 3, 10 evaluable participants completed at least 3 treatment cycles (control n=3; cavitation n=7). Objective response rate was 66.7% in the control arm versus 85.7 % with cavitation. **Conclusions:** Cavitation with sonosensitive particle infusion demonstrated a favourable safety profile, increased intratumoural antibody delivery, and showed early signals of enhanced anti-tumour activity, supporting further clinical development. Clinical trial information: ISRCTN17598292. Research Sponsor: National Institute for Health Research (NIHR), UK.

Cohort	Number treated	Primary endpoint	Key findings
1	9	Safety	No grade 3 or higher events; sustained cavitation in the target region.
2	7	Drug levels	Increased cetuximab concentrations in the tumours treated with cavitation (7.1 vs 3.7 ng/mL)
3	10	Radiological response	Enhanced radiological response (ORR of 85.7% in patients treated with cavitation)

ORR = objective response rate based on FDG PET-CT.

3550 Poster Session

Negative hyperselection as a predictive biomarker of benefit from first-line doublets + anti-EGFRs/bevacizumab (bev) in microsatellite stable (pMMR/MSS) *RAS* and *BRAF* wild-type (wt) and HER2− metastatic colorectal cancer (mCRC): An individual patient data pooled analysis of seven clinical trials (CTs). First Author: Marco Maria Germani, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy

Background: Primary tumor sidedness is nowadays a major driver for the choice of biologics in the first line of pMMR/MSS *RAS* and *BRAF* wt mCRC patients (pts). It has been suggested that it might be replaced by a broader molecular profiling, but the evidence provided by individual trials is uncertain for the adoption of different panels and underrepresentation of gene-altered cases. We recently showed that HER2+ status does not predict resistance to first-line doublets + anti-EGFRs. **Methods:** We collected individual patient data from 7 CTs in first-line mCRC: TRIBE2, TRIPLETE, VALENTINO, CAPRI-2, FIRE-3, PARADIGM and CALGB/SWOG80405. pMMR/MSS *RAS* and *BRAF* wt and HER2− cases treated with doublets + anti-EGFRs/bev with available NGS data were included. Hyperselected tumors were those without *MET+* status, *ALK/ROS1/NTRKs/RET* fusions, and *HER2/PIK3CAexon20/PTEN/AKT1* mutations. Propensity score adjustment was used to assess clinical outcomes (aHR and aOR) according to first-line doublets + anti-EGFRs/bev. **Results:** Out of 1198 included pts, 990 (83%) had left-sided and 208 (17%) right-sided tumors. Anti-EGFR based regimens were associated with numerically longer OS (aHR: 0.86) in left-sided tumors, but not in right-sided ones (aHR: 0.98), with an insignificant p for interaction [int] = 0.60). Hyperselected and gene-altered cases were 1077 (91%) and 121 (9%), respectively. The anti-EGFR benefit in OS was magnified in hyperselected pts (aHR: 0.83), with an aHR of 1.16 in gene-altered ones (p_{int} =0.11, adjusted also for tumor sidedness). As reported in the table, there was no interaction between the effect of biologics and primary tumor location either in the hyperselected (p_{int} =0.86) or in the gene-altered group (p_{int} =0.41). **Conclusions:** Hyperselection outperforms tumor sidedness as a predictive marker of benefit from doublets + anti-EGFR/bev in pMMR/MSS *RAS/BRAF* wt and HER2− mCRC. The OS benefit from anti-EGFR-based regimens is restricted to pts with hyperselected tumors, independently of primary tumor location. Therefore, in hyperselected mCRC, doublets + anti-EGFRs remain the standard for left-sided pts and may deserve consideration in right-sided ones. A phase II trial of fruquintinib combined with cadonilimab in refractory MSS/pMMR colorectal cancer with pulmonary metastases. First Author: Mengzhou Guo, Department of Medical Oncology, Cancer Center, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Immunotherapy for metastatic colorectal cancer (mCRC) with microsatellite stable/proficient mismatch repair (MSS/pMMR) remains limited. Emerging evidence suggests that the combination of antiangiogenic agents and immune checkpoint inhibitors (ICIs) exhibits synergistic antitumor effects in refractory MSS/pMMR mCRC, particularly among patients (pts) with isolated lung metastases. This open-label, single-arm, phase II trial aims to evaluate the efficacy and safety of fruquintinib plus cadonilimab in pts with MSS/pMMR mCRC who progressed after at least two prior lines of therapy. **Methods:** Patients aged≥18 years, with pathologically confirmed MSS/pMMR mCRC presenting pulmonary metastases and no liver metastases, and who had experienced failure of at least second-line therapy were enrolled. Eligible patients received oral fruquintinib (3 mg once daily) plus intravenous cadonilimab (6 mg/kg every two weeks) until disease progression, unacceptable toxicity, or withdrawal of consent. Tumor assessments were performed every 8 weeks. The primary endpoint was objective response rate (ORR), and secondary endpoints included overall survival (OS), progression-free survival (PFS), disease control rate (DCR), and safety. **Results:** From February 2024 to June 2025, 37 pts were enrolled [median age 61 years, 68% male, 89% ECOG 0-1, 62% RAS mutant, 30% 3L+, 73% prior bevacizumab, 3 pts prior immunotherapy]. The ORR was 31.4%, and the DCR was 71.4%. Median PFS was 6.1 months (95%CI: 4.8-7.5), while OS data remain immature. Moreover, the patients with a history of liver metastases showed a trend toward shorter PFS compared to those without (4.0 vs. 6.9 months; P = 0.194). The most common treatment-related adverse events (AEs) were hypothyroidism (43%), elevated ALT/AST (27%), hypertension (24%), diarrhea (24%), thrombocytopenia (19%), hand-foot syndrome (16%), and rash (16%). Grade ≥3 treatment-related AEs occurred in 10 (27%) pts. Serious adverse events (SAEs) were reported in 5 pts, with no grade 4 or 5 SAEs observed. **Conclusions:** The combination of fruquintinib and cadonilimab demonstrated promising clinical activity and a manageable safety profile in patients with refractory MSS/pMMR mCRC. Clinical trial information: ChiCTR2400079429. Research Sponsor: National Natural Science Foundation of China (82573146).

Detecting *MTAP* loss in liquid biopsies from patients with clinically advanced colorectal cancer (CRC). First Author: Xuanyi Li, Yale Cancer Center, New Haven, CT

Background: Homozygous loss of the *MTAP* gene (*MTAP* loss) is an emerging biomarker guiding investigational use of PRMT5 and MAT2A inhibitors in a wide variety of tumor types, including CRC. Detecting copy number changes, including homozygous losses, in solid tumors is often challenging and requires robust assay and analytic pipeline especially when the amount of extracted DNA is small. In clinically advanced CRC, small endoscopic and needle-based biopsies are often used for diagnosis, imposing significant limitations on immunohistochemistry (IHC) and comprehensive genomic profiling (CGP) required for treatment selection and clinical trial enrollment. We assessed whether liquid biopsy (LBx) CGP could provide treatment-relevant information on *MTAP* loss compared to tissue biopsy (TBx) CGP for patients with CRC. **Methods:** Hybrid capture-based CGP was performed on 46,173 clinically advanced CRC (stage III, IV) TBx cases using the FoundationOne CDx assay and on 9,049 LBx cases using the FoundationOneLiquid CDx assay. Tumor fraction (TF) for each LBx sample was determined using assessments of aneuploidy and variant allele frequencies, as previously described. **Results:** *MTAP* loss was detected in 498 (1.08%) TBx cases. For LBx, detection of *MTAP* loss increased with higher TF, with detections observed only at TF ≥5% (Table 1). With TF ≥5%, the frequency of *MTAP* loss detection was comparable to or exceeds that observed with TBx. Regarding complete vs partial *MTAP* exon loss, TBx and LBx showed similar patterns, with complete loss of all 8 *MTAP* exons observed in 85.7% of TBx cases and 84.5%-89.8% in LBx cases, increasing in higher TF levels. **Conclusions:** LBx emerges as a promising tool for detecting *MTAP* loss in clinically advanced CRC, with *MTAP* loss detection rates approaching those of TBx when LBx TF is ≥5%, while detection is limited at lower TF levels. Incorporation of LBx for *MTAP* loss detection may expand patient access to biomarker-driven clinical trials involving PRMT5 and MAT2A inhibitors for patients with clinically advanced CRC when sufficient tissue for tissue-based CGP is not feasible. Research Sponsor: None.

***MTAP* loss detected by TBx and LBx in clinically advanced CRC.**

Cohort (cumulative)*	*MTAP* no loss	*MTAP* loss	*MTAP* loss frequency
TBx (n=46173)	45675	498	1.08%
LBx TF ≥0% (100% of LBx, n=9049)	9002	47	0.52%
LBx TF ≥1.0% (62.7% of LBx)	5624	47	0.83%
LBx TF ≥5.0% (48.7% of LBx)	4359	47	1.07%
LBx TF ≥10.0% (41.5% of LBx)	3712	46	1.22%
LBx TF ≥20.0% (31.5% of LBx)	2812	38	1.33%
LBx TF ≥30% (24.8% of LBx)	2214	29	1.29%

*TF thresholds represent cumulative subsets of the LBx cohort.

Tumor cell-intrinsic programs of metabolic adaptation and immune evasion in colorectal cancer liver metastases (CRCLMs). First Author: Xuanyi Li, Yale Cancer Center, New Haven, CT

Background: CRCLMs account for the majority of colorectal cancer (CRC)-related mortality and represent a key site of immunotherapy resistance. The tumor cell-intrinsic molecular programs enabling adaptation to the liver microenvironment and immune evasion remain poorly defined. **Methods:** We performed spatial whole transcriptomic analysis of 189 patient-matched primary CRC and CRCLM samples from two independent cohorts (Cohort 1 = 47; Cohort 2 = 141). Samples were represented using tissue microarrays and analyzed using the GeoMx Digital Spatial Profiling (DSP) platform. Two ROIs (tumor cell [CK] and stroma [DAPI]) were analyzed per sample, with analyses focused on tumor cells. Differential expression analyses were conducted independently within each cohort. Results were integrated using Fisher's combined probability method for batch-aware meta-analysis. Expression of selected transcripts in tumor and matched non-tumor tissue in TCGA and associated survival outcomes were evaluated using the GEPIA2 webtool. Gene set enrichment analysis (GSEA) was applied to identify consistently altered biological pathways. Exploratory LASSO regression using normalized expression values identified gene sets distinguishing liver metastases from primary tumors. **Results:** We identified multiple genes consistently enriched in malignant cells from CRCLM compared to primary CRC. Prioritized genes include MMP10 (logFC = 0.41, p = 0.007), KRT17 (logFC = 0.87, p < 0.001) and PLA2G2A (logFC = 0.72, p = 0.002), all showing higher tumor expression relative to normal tissue, association with unfavorable survival, and translational relevance (Table 1). GSEA revealed enrichment of acute-phase response (NES = 1.86, FDR = 0.003), complement activation (NES = 1.81, FDR = 0.002) and xenobiotic metabolism (NES = 1.71, FDR = 0.006) in liver metastases, together with reduced antigen processing and presentation (NES = -1.78, FDR = 0.012). Exploratory LASSO regression yielded cohort-specific gene signatures with limited gene-level overlap but convergence on shared biological programs distinguishing CRCLM from primary CRC, including epithelial and metabolic pathways. Of note, PLA2G2A was among the selected features in an independent cohort, reinforcing its association with CRCLM. **Conclusions:** We identified tumor cell-intrinsic programs in CRCLMs consistent with cellular metabolic adaptations and immune evasion with potential relevance in disease progression and treatment resistance. Our analyses also identified genes, including MMP10, KRT17, and PLA2G2A, as potential therapeutic vulnerabilities in CRCLMs for future investigation. Research Sponsor: None.

Prioritized liver metastasis-enriched genes.

Gene	Translational Relevance
MMP10	Enzymatic target; inhibitor scaffolds exist
KRT17	Tumor-specific biomarker/pathway proxy
PLA2G2A	Enzymatic target; pathway inhibition feasible

Tumor shrinkage and depth of response with fruquintinib in patients with metastatic colorectal cancer: Results from FRESCO and FRESCO-2. First Author: Elena Elez, Vall d'Hebron Barcelona Hospital Campus, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Background: In metastatic colorectal cancer (mCRC), early tumor shrinkage (ETS) and depth of response (DpR) are predictors of overall survival (OS) and progression-free survival (PFS). Durable stable disease (SD) also reflects disease control and can contextualize PFS and OS improvements. The phase 3 FRESCO (F) and FRESCO-2 (F2) trials of fruquintinib vs placebo in patients (pts) with mCRC showed significantly longer OS (F median: 9.3 vs 6.6 months [mo], HR 0.65, P<0.001; F2 median: 7.4 vs 4.8 mo, HR 0.66, P<0.001) and PFS (F median: 3.7 vs 1.8 mo, HR 0.26, P<0.001; F2 median: 3.7 vs 1.8 mo, HR 0.32, P<0.001) with fruquintinib. We report a post-hoc analysis of tumor shrinkage (TS), ETS, and DpR, and the correlation with OS and PFS in F and F2. **Methods:** Pts were randomized to receive fruquintinib + best supportive care (BSC; F n=278; F2 n=461) or placebo + BSC (F n=138; F2 n=230). Tumors were assessed at screening and every 8 weeks until progressive disease (PD). TS was defined as a decrease from baseline in the sum of the longest diameters of target lesions; ETS was TS by the first post-treatment assessment; duration of TS (DTS) was time from first TS to first tumor size increase, PD, or death; in pts with best overall response of SD, duration of SD was assessed as the time from first occurrence of SD to PD/death; and DpR was the maximum percentage change from baseline in the sum of the longest diameters of target lesions. OS and PFS were assessed in pts who received fruquintinib and had TS/ETS. **Results:** In F, 129 (46%) fruquintinib-treated pts had TS, of which 124 (45%) achieved ETS; with placebo, 5 pts (4%) had TS and ETS. In F2, similarly, 178 (39%) fruquintinib-treated pts had TS, of which 154 (33%) achieved ETS; with placebo, 15 pts (7%) had TS and 13 pts (6%) had ETS. In pts with TS in F and F2, median DTS with fruquintinib was 1.9 and 2.0 mo, respectively. Median duration of SD was longer with fruquintinib vs placebo in both F (5.5 vs 3.7 mo) and F2 (5.6 vs 3.7 mo). Magnitude of DpR was greater with fruquintinib vs placebo in both trials. In F and F2, median OS and PFS in pts who received fruquintinib were longer in those who achieved TS and ETS vs the ITT fruquintinib arm (Table). **Conclusions:** ETS was observed in most fruquintinib-treated pts with TS in both F and F2 (F: 96% [124/129 pts]; F2: 87% [154/178 pts]); pts with both TS and ETS showed longer median OS and PFS compared with the fruquintinib ITT population. These data indicate that TS and ETS appear to be predictors of OS and PFS outcomes, and support the prognostic relevance of TS, ETS, and DpR in pts with mCRC. Clinical trial information: NCT02314819 and NCT04322539. Research Sponsor: Takeda Pharmaceuticals U.S.A., Inc., Cambridge, MA.

OS and PFS in pts who received fruquintinib with TS/ETS vs the ITT fruquintinib arm in F and F2.

Months (95% CI)	With TS	With ETS	ITT Fruquintinib arm
F	**n = 129**	**n = 124**	**N = 278**
OS	12.1 (10.8–14.9)	11.6 (10.7–14.9)	9.3 (8.2–10.5)
PFS	5.5 (5.5–7.3)	5.5 (5.5–6.6)	3.7 (3.7–4.6)
F2	**n = 178**	**n = 154**	**N = 461**
OS	10.9 (9.9–12.5)	10.8 (8.9–12.7)	7.4 (6.7–8.2)
PFS	5.6 (5.4–6.2)	5.6 (5.1–5.8)	3.7 (3.5–3.8)

Evaluation of circulating tumor DNA (ctDNA) following liver resection in a high-risk population with colorectal liver metastases. First Author: John Neil Primrose, Cancer Sciences, University of Southampton, Southampton, United Kingdom

Background: Liver resection is routinely performed for oligometastatic colorectal cancer (CRC). ctDNA analysis is becoming important in the management of primary CRC following surgery, but in patients with liver metastases, its role is less clear. This study aimed to evaluate the performance of a plasma ctDNA assay for early detection of recurrence in patients with liver only CRC metastases post surgical resection. The cohort included patients who had inoperable disease prior to induction chemotherapy and those having repeat resections. Patients with the primary cancer in situ were included if a synchronous resection was performed. **Methods:** 61 patients (42 male, median age 68 [range 41-85]) were studied. All patients had CRC liver metastases as the sole metastatic site on evaluation by CT and MRI. Patients were followed up clinically with regular CT imaging. Plasma samples were collected at baseline (pre-surgery, n = 55) and 5 days to 1+ year after surgery, and were tested retrospectively on a blood-only, tumor-agnostic, targeted methylation assay that interrogates informative methylation regions for signal indicative of ctDNA using a machine learning classifier (GRAIL, Inc., Menlo Park, CA). **Results:** ctDNA was detected in 94.5% (52/55) of patients at the pre-surgery timepoint. During clinical surveillance, 46 developed recurrence, 5 had no recurrence for at least 2 years after surgery, and 10 had follow-up for less than 2 years. Among patients with recurrence, ctDNA was detected in 80.4% (37/46) of patients before recurrence, with a median lead time of 245 days [IQR: 65 - 393 days]. All five patients who remained recurrence-free for at least 2 years had undetectable ctDNA following surgery. ctDNA was detected in 57.8% (26/45) of patients who recurred and had plasma collected within 3 months following surgery. Recurrence-free survival (RFS) was significantly lower in patients with ctDNA detected within 3 months after surgery (median RFS 272 vs. 593 days, log-rank p-value < 0.01). **Conclusions:** ctDNA analysis using a methylation-based assay allowed the detection of minimal residual disease and the prediction of recurrence in many patients following resection of CRC liver metastases. These data support the potential use of this biomarker for patient management pending confirmation in prospective clinical studies. Research Sponsor: None.

Screening for intrinsic and acquired resistance mutations to anti-EGFR in real-world MSS colorectal cancer data. First Author: Matthew B. Maxwell, Tempus AI, Inc., Chicago, IL

Background: Anti-EGFR (cetuximab, panitumumab) plus doublet chemotherapy is the first line standard of care for metastatic MSS left-sided RAS/RAF WT colorectal cancer (CRC). However, anti-EGFR clinical efficacy is limited by intrinsic and acquired resistance. Defining anti-EGFR intrinsic resistance mutations could improve patient selection for anti-EGFR treatment while defining anti-EGFR acquired resistance mutations could enable early detection of resistance via liquid biopsy. **Methods:** The intrinsic resistance cohort consisted of 163 metastatic MSS RAS/RAF WT colon adenocarcinoma patients treated in the first line with anti-EGFR with a DNA-seq sample collected before treatment (Tempus xT or xF). We screened mutations for anti-EGFR intrinsic resistance defined as HR $>$ 2 for PFS via univariate CoxPH models. The anti-EGFR acquired resistance cohort consisted of 228 MSS CRC patients with a DNA-seq sample (xT or xF) within 12 months prior to and 0.5-24 months post treatment. We defined acquired resistance mutations as those significantly enriched post-treatment vs pre-treatment via McNemar test. An anti-VEGF acquired resistance cohort of 748 MSS CRC patients was used as a control. Enrichment of targetable gene fusions post-treatment was assessed via Wilcoxon test. FDR $<$ 0.05 was considered significant. **Results:** The screen for intrinsic resistance mutations returned a single significant hit of *PIK3CA* non-exon 9 mutations (~3%, $p <$ 0.01), while *PTEN* deletions (~2%), which are functionally similar, were also associated with shorter PFS but did not reach significance (p=0.08). *PIK3CA* non-exon 9 mutation or *PTEN* deletion were detected in ~5% of patients (n=9) and were associated with shorter PFS (HR = 3.6, 95% CI: 1.7-7.6, $p < 0.001$) and OS (HR = 2.6, 95% CI: 1.03-6.5, $p < 0.05$). Median PFS and OS were 6 and 14 months for patients with these resistance alterations, versus 11 and 29 months for non-altered patients. In a CoxPH model including age, sex, sidedness, and collection procedure, these alterations maintained a significant association with PFS (HR =5.2, 95% CI: 2.2-12.4, $p < 0.01$) but not OS (HR=2.7, 95% CI: 0.9-8.9, p=0.08). Analysis of acquired resistance to anti-EGFR treatment yielded significant mutation hits—*KRAS, NRAS, EGFR*, and *MAP2K1*—as well as significant enrichment of targetable fusions (*BRAF, FGFR, NTRK, ALK, ROS1, RET, NRG1*). No mutations or fusions were observed to be associated with anti-VEGF acquired resistance. **Conclusions:** Patients harboring *PIK3CA* non-exon 9 mutation or *PTEN* deletion displayed intrinsic resistance to anti-EGFR therapy despite being RAS/RAF WT and may be offered anti-EGFR therapy per oncology guidelines. This small underrepresented subset of patients may not benefit from anti-EGFR therapy. Prospective clinical validation will be needed to determine if this subset of PI3K pathway alterations has utility in optimizing first line therapy selection. Research Sponsor: FightCRC.

BAYONET trial: A multicenter phase II trial of staged combination with encorafenib + binimetinib + cetuximab following encorafenib + cetuximab in patients with *BRAF*V600E-mutant metastatic colorectal cancer. First Author: Takeshi Yamada, Department of Gastroenterology, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan

Background: While the doublet combination of encorafenib (ENCO) + cetuximab (CET) is a standard treatment for patients with *BRAF*V600E-mutant metastatic colorectal cancer (mCRC), poor prognosis is expected after disease progression. As resistant mechanisms to BRAF + EGFR blockade, several MAPK pathway alterations, including *RAS* and *RAF* mutations, have been reported, suggesting that additional blockade of MAPK signaling may be an effective strategy. Furthermore, preclinical studies demonstrated that *BRAF* V600E-mutant colorectal cancer cell lines resistant to BRAF inhibitor + anti-EGFR antibody were sensitive to the triple combination of BRAF inhibitor + MEK inhibitor + anti-EGFR antibody. **Methods:** BAYONET is a single-arm, multicenter phase II trial designed to evaluate the efficacy and safety of the staged combination with ENCO, binimetinib (BINI), plus CET for patients with *BRAF* V600E-mutant mCRC who were refractory to ENCO plus CET. The main eligibility criteria are as follows: *RAS* wild-type/*BRAF* V600E-mutant mCRC; age $\geq$ 20; ECOG PS 0 or 1; within 4 weeks from the last administration of previous ENCO or CET; no administration of other systemic therapy after refractoriness to ENCO + CET; complete response, partial response, or $\geq$4 months of stable disease was observed in the previous ENCO + CET. Included patients receive the combination treatment of ENCO (300 mg once a day) + BINI (45 mg twice a day) + CET (400 mg/m^2 initial dose and then 250 mg/m^2 once a week) in a 28-day cycle. The primary endpoint of this trial is 12-week progression-free survival (PFS) rate. The targeted sample size was calculated to be 30 on the basis of a power of 80%, a significance level of 10% (one-sided), a threshold of 20%, and an expected 12-week PFS rate of 40%. Pretreatment ctDNA analysis was performed using the Guardant360 assay. **Results:** Among 30 patients, all had microsatellite-stable or mismatch repair-proficient tumors, and 21 (70%) of patients received prior $<$3 treatment lines. The locally assessed 12-week PFS rate was 33.3% (80% CI, 21.8–46.6). Since the lower limit of 80% CI exceeded 20%, the primary endpoint was met. With a median follow-up duration of 9.8 months (range, 2.1–35.8), the median PFS was 2.0 months (95% CI, 1.6–4.2), and the median overall survival was 14.7 months (95% CI, 7.1–18.7). Patients who achieved 12-week PFS had significantly lower ctDNA *BRAF* V600E VAF (median, 0.2%; range, 0-18%) compared to those who did not achieve it (median, 4.2%; range, 0-41%). Grade 3 or higher adverse events were observed in 50% of patients, most commonly anemia (20%), creatine kinase increase (13%), and diarrhea (10%). No new safety signal was identified. **Conclusions:** Staged combination with ENCO+BINI+CET showed potential to achieve disease control for patients with *BRAF* V600E-mutant mCRC who were refractory to ENCO+CET. Clinical trial information: jRCTs031210510. Research Sponsor: ONO PHARMACEUTICAL CO., LTD.

FOLFOXIRI/bevacizumab in microsatellite stable (pMMR/MSS) *RAS* and *BRAF* wild-type "gene-altered" metastatic colorectal cancer (mCRC): The HYPERTRIBE study. First Author: Marco Maria Germani, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy

Background: Negative hyperselection may allow patient refinement for the use of anti-EGFRs in chemo-naïve pMMR/MSS, *RAS* and *BRAF* wild-type (wt) mCRC patients. However, outcomes are poor with both doublets/anti-EGFRs and doublets/bevacizumab (bev) among patients with gene-altered tumors. We investigated the efficacy of chemotherapy intensification with FOLFOXIRI/bev in this subgroup. **Methods:** We prospectively selected mCRC patients with pMMR/MSS, *RAS* and *BRAF* wt tumors harbouring at least one genomic alteration potentially implied with anti-EGFR resistance in published studies (*ERBB2 / PIK3CAexon20 / PTEN / AKT1 / NTRKs / ERBB3 / NF1 / MAP2K1-2-4 / AKT2 / EGFR* / subclonal *RAS* mutations; *ERBB2 / MET / ERBB3 / FGFR2 / IGF1R / KRAS / ARAF / AKT1-2* amplification; *ALK / ROS1 / NTRKs / RET* fusions; *EGFR* rearrangements; *PTEN / NF1 loss),* treated with upfront FOLFOXIRI/bev in 11 Italian centres. Assuming that the use of FOLFOXIRI/bev could lead to an increase in median PFS (mPFS) from 9 (as observed with doublets/anti-EGFRs) to 16 months (mos), with one-sided α and β errors of 0.10 and 0.20, respectively, 33 patients were needed. Secondary endpoints were overall survival (OS) and objective response rate (ORR). Outcomes were paired with a propensity score-matched external cohort of pMMR *RAS* and *BRAF* wt gene-altered patients treated with doublets/anti-EGFRs in clinical trials. **Results:** 35 patients were included. Main patients' characteristics were: median age 54 years, ECOG PS 0 83%, left-sided tumours 54%. Amplification in *ERBB2* and *MET* genes accounted for 26% and 6% of cases, respectively. The most frequent mutant gene was *ERBB2* (17%), followed by *MAP2K1* (9%), *PTEN* (9%), *NF1* (6%), *PIK3CAexon20* (3%), *EGFR* (3%). Subclonal *RAS* mutations were found in 14% of tumors. Fusions, detected in *ALK* and *RET* genes, accounted for 6% of cases. FOLFOXIRI/bev resulted into a mPFS of 12.3 mos (80% CI: 9.2 – 14.3 mos, Brookmeyer-Crowley test p = 0.023), an ORR of 74% and a mOS of 35.9 mos. PFS and OS with FOLFOXIRI/bev were longer than those achieved in the propensity score-matched cohort of patients treated with doublets/anti-EGFRs (mPFS: 12.3 vs 10.3 mos, HR: 0.74, 95% CI: 0.45 – 1.21, p=0.226; mOS: 35.9 vs 27.2 mos, HR: 0.57, 95% CI: 0.32 – 1.03, p=0.058). Similarly, a numerical advantage in ORR was reported (74% vs 63%, OR: 1.69 95% CI 0.61 – 4.88, p=0.303). No interaction (int) between the effect of treatment and primary tumor location was evident (p_{intPFS}=0.267; p_{intOS}=0.459; p_{intORR}=0.866). **Conclusions:** Waiting for efficacy results about the upfront use of targeted treatments directed against specific molecular subgroups, FOLFOXIRI/bev may be the preferred first-line option for clinically fit pMMR/MSS *RAS* and *BRAF* wt mCRC patients harbouring at least one genomic alteration of potential resistance to anti-EGFRs, regardless of primary tumor sidedness. Research Sponsor: Gruppo Oncologico del Nord Ovest (GONO); NextGenerationEU through the Italian Ministry of University and Research; Federation of Italian Cooperative Oncology Groups (FICOG) and Associazione Italiana Oncologia Medica (AIOM).

3561 **Poster Session**

Tumor load change as a functional biomarker for prognosis and treatment modulation in metastatic colorectal cancer (mCRC): Individual patient data (IPD) analysis of 12 randomized trials. First Author: Alexej Ballhausen, Department of Hematology, Oncology and Tumorimmunology, Charité-Universitätsmedizin Berlin, Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin, Germany

Background: The use of overall response rate (ORR) and progression-free survival (PFS) as surrogacy of overall survival (OS) has limitations in mCRC. Change in tumor load (ΔTL; tumor burden at progressive disease [PD] vs baseline) at treatment failure may reflect tumor aggressiveness and resistance biology. We evaluated the prognostic value of ΔTL in mCRC using IPD from twelve randomized first-line trials. **Methods:** IPD from ATEZOTRIBE, FIRE3, FIRE4, FIRE4.5, MACBETH, ML22011, MOMA, PANAMA, TRIBE, TRIBE2, TRIPLETE, and VALENTINO were pooled. ΔTL was defined as the ratio of the sum of longest target lesion diameters at PD vs baseline, per RECIST. Primary endpoint was OS; secondary endpoints included post-progression survival (PPS). Estimated marginal means were controlled for treatment type. Associations between ΔTL and outcomes were assessed using Cox models adjusted for prespecified baseline tumor burden and clinical covariates (ECOG, age, sex, sidedness, *RAS/BRAF* status, metastatic patterns, previous therapies). Incremental prognostic value beyond early tumor shrinkage (ETS) and depth of response (DpR) was assessed using likelihood ratio testing. Effect modification by treatment regimen was evaluated using ΔTL $\times$ treatment interaction terms for EGFR- vs VEGF-based therapy and for triplet vs doublet-chemotherapy across trials. **Results:** A total of 4852 patients evaluable for ΔTL were included. Mean ΔTL was 0.63 (SD 0.45) and significantly lower in patients receiving EGFR- vs VEGF-based therapy (0.58 vs 0.66, $p<0.001$) and triplet vs doublet chemotherapy (0.57 vs 0.67, $p<0.001$). Lower ΔTL (lower tumor load at PD vs baseline) was associated with better OS (HR 0.58 [95% CI 0.55–0.61], $p<0.001$) and PPS (HR 0.65 [0.61–0.69], $p<0.001$) after adjustment for baseline tumor burden and clinical covariates. For OS, ΔTL added prognostic information beyond ETS (likelihood ratio χ^2 = 282.13, $p<0.001$) and DpR (likelihood ratio χ^2 = 121.91, $p<0.001$). Lower ΔTL was associated with improved OS in patients receiving EGFR- (n = 1609; HR 0.62 [0.58–0.67], $p<0.001$) and VEGF-based therapy (n = 1916; HR 0.39 [0.35–0.43], $p<0.001$); doublet (n = 2177; HR 0.61 [0.57–0.65], $p<0.001$) and triplet (n = 1348; HR 0.34 [0.30–0.38], $p<0.001$) chemotherapy, with significant ΔTL $\times$ treatment interaction (VEGF vs EGFR: HR 0.50 [0.46–0.54], $p<0.001$; triplet vs doublet: HR 0.60 [0.54–0.66], $p<0.001$) after adjustment for treatment regimen, *RAS/BRAF* status and other clinical covariates. **Conclusions:** TL appears to be a strong, independent prognostic marker for OS and PPS in mCRC. ΔTL seems to vary by biologic and chemotherapy intensity, indicating it captures differential treatment effect/resistance not captured by ORR or PFS. Prospective validation as an early, treatment-sensitive prognostic endpoint is warranted. Research Sponsor: None.

Single-cell atlas of peripheral blood immune landscape in pMMR/MSS rectal cancer treated with neoadjuvant chemoradiotherapy and PD-1 blockade. First Author: Leqi Zhou, Department of Colorectal Surgery, Changhai Hospital, Naval Medical University, Shanghai, China

Background: Most colorectal cancer (CRC) patients exhibit normal mismatch repair function/microsatellite stability (pMMR/MSS), presenting a poor response to immune checkpoint inhibitor monotherapy. Neoadjuvant chemoradiotherapy (nCRT) combined with PD-1 inhibitors can enhance the efficacy of immunotherapy. However, the peripheral immune dynamics underlying this combination remain poorly understood. **Methods:** In this study, we selected 15 patients from the CHOICE I trial (ChiCTR2100042785) who received nCRT combined with PD-1 inhibitors. A total of 55 peripheral blood mononuclear cell (PBMC) samples were collected at three critical time points: pre-treatment baseline, during radiotherapy, and during immunotherapy. All samples underwent single-cell RNA sequencing (scRNA-seq) analysis, complemented by paired TCR/BCR profiling, to comprehensively map the dynamic evolution of the peripheral immune landscape during combined therapy. **Results:** We analysed 223,363 high-quality single cells and classified them into 11 distinct immune phenotypes using classical marker genes, revealing treatment-related immune dynamics. TCR clonal tracking revealed divergent dynamics that CD8+ T cells exhibited high clonal persistence (Jaccard index 0.1–0.23), significantly greater in responders than non-responders, underscoring their pivotal role in antitumor immunity. In contrast, CD4+ T cells (particularly T follicular helper cells) showed minimal clonal overlap (< 0.03), consistent with rapid turnover. Monocyte analysis uncovered fundamental differences. Monocytes from non-responders displayed enhanced yet dysfunctional antigen presentation alongside immunosuppressive features, including specific expansion of the pro-inflammatory Mono_CD14_IL1B subset characterized by high immunomodulatory molecule expression. Conversely, monocytes in responders exhibited robust type I interferon signaling. B-cell analyses revealed that responders preferentially underwent plasma-cell differentiation, whereas B cells from NR retained an antigen-presenting–like phenotype. NK-cell analysis revealed an expanded, activated cytotoxic pool in responders (featuring CD38+, KIR3DL1+ subsets), whereas non-responders showed dominance of KLRC2+ NK cells, suggesting a dysfunctional state. These efficacy-linked changes across immune populations collectively map the systemic immune landscape under combination therapy. **Conclusions:** This study provides a comprehensive single-cell atlas of peripheral immune remodeling during nCRT combined with PD-1 inhibitors in pMMR/MSS rectal cancer, offering crucial insights for future patient stratification and personalized combination strategies. NALIRIFOX plus targeted therapy as first-line treatment for metastatic colorectal cancer: A phase I study. First Author: Xiaojing Xu, Department of Medical Oncology, Zhongshan Hospital, Fudan University, Shanghai, China

Background: FOLFOXIRI combined with targeted therapy is recommended for metastatic colorectal cancer (mCRC) patients suitable for intensive treatment or conversion surgery. However, the combination of irinotecan liposome, oxaliplatin, fluorouracil (NALIRIFOX) in mCRC remains uninvestigated. This Phase I study aimed to determine the maximum tolerated dose (MTD) of irinotecan liposome in this combined therapy for mCRC. **Methods:** Patients with histologically confirmed and initially unresectable mCRC were enrolled. In the dose-escalation phase (Phase Ia), a 3+3 design was utilized. Eligible patients received fixed doses of oxaliplatin (85mg/m^2), fluorouracil (2400mg/m^2) and bevacizumab (5mg/kg), while the dose of irinotecan liposome was escalated starting from 60mg/m^2. If a dose-limiting toxicity (DLT) occurs at 60mg/m^2, the dose can be reduced to 50mg/m^2. Toxicity was evaluated using Common Terminology Criteria for Adverse Events (CTCAE5.0). In the dose-expansion phase (Phase Ib), irinotecan liposome was administered at the recommended dose from Phase Ia. Based on the RAS/BRAF gene status, either bevacizumab or cetuximab was combined with NALIRIFOX. The safety and efficacy of the combination were further assessed in Phase Ib. **Results:** From March 2024 to March 2025, 9 patients in the dose-escalation phase and 64 patients in the dose-expansion phase were enrolled, included 48 males and 25 females with a median age of 57 years. The MTD of irinotecan liposome was determined to be 50mg/m². Identified DLTs included grade 3 diarrhea and febrile neutropenia. As of January 15, 2026, 65 patients had at least one tumor assessment. The objective response rate (ORR) was 81.5% and the disease control rate (DCR) was 100.0%. The median PFS was 12.3 months (95% CI 9.8-14.7). The rate of R0 resection was 12.3%. The most common ≥grade 3 treatment-related adverse events (TRAEs) were diarrhea (18.4%) and neutropenia (14.5%). **Conclusions:** Irinotecan liposome at a dose of 50 mg/m² in the NALIRIFOX regimen showed manageable safety and promising efficacy as first-line treatment for mCRC. Clinical trial information: NCT06225622. Research Sponsor: None.

***KMT2C* mutation to identify an immunotherapy-sensitive subset of gastrointestinal cancers: A large real-world analysis.** First Author: Bruno Bockorny, Beth Israel Deaconess Medical Center, Boston, MA

Background: *KMT2C* (MLL3) encodes a histone methyltransferase involved in enhancer regulation and DNA damage repair. Loss-of-function *KMT2C* mutations occur in approximately 4–7% of gastrointestinal cancers and represent one of the most recurrent chromatin regulator alterations across GI malignancies. Preclinical studies demonstrate that *KMT2C* deficiency impairs homologous recombination–mediated DNA repair and increases tumor immunogenicity. We hypothesized that *KMT2C* mutations define a biologically distinct subset of GI cancers associated with enhanced responsiveness to immune checkpoint inhibitors (ICI). **Methods:** Using the Tempus Lens Platform, we identified patients with colorectal cancer (CRC), pancreatic ductal adenocarcinoma (PDAC), or gastroesophageal adenocarcinoma (GEA) who underwent Tempus xT DNA and RNA sequencing within a de-identified multimodal real-world dataset. Clinical and molecular features were compared between *KMT2C*-mutant (MUT) and wild-type (WT) tumors. Real-world progression-free survival (rwPFS) and overall survival (rwOS) following ICI initiation were estimated by Kaplan–Meier methods and compared using log-rank tests. Risk-set adjustment was applied to address left truncation and mitigate immortal time bias. **Results:** Among 14,413 patients, 83% had stage IV disease; CRC comprised 58.1%, PDAC 23.7%, and GEA 18.2%. *KMT2C* mutations were identified in 4.1% of CRC, 3.4% of PDAC, and 4.3% of GEA. Across all tumor types, *KMT2C*^{MUT} tumors had significantly higher tumor mutational burden (TMB) compared with WT (CRC: 39.2 vs 4.7 mut/Mb; PDAC: 3.68 vs 3.16; GEA: 7.9 vs 4.6; all $p \leq 0.02$). TMB-High status (≥10 mut/Mb) and MSI-High status were markedly enriched in *KMT2C* MUT tumors (CRC MSI-H: 57% vs 2.6%; PDAC: 6.9% vs 0.1%; GEA: 38% vs 2%; all $p < 0.001$). High Immune Profile Score (IPS) was more frequent in *KMT2C*^{MUT} versus WT tumors in CRC (35% vs 8.3%, $p < 0.001$) and GEA (36% vs 19%, $p < 0.001$). Following ICI, rwPFS was not reached in both *KMT2C*^{MUT} CRC and *KMT2C*^{MUT} GEA compared with 6.2 and 6.0 months in WT tumors (CRC $p = 1.1 \times 10^{-17}$; GEA $p = 0.004$). rwOS was significantly improved in CRC *KMT2C*^{MUT} versus WT (not reached vs 20.2 months; $p = 0.0001$). **Conclusions:** *KMT2C* mutations identify a molecularly and immunologically distinct subset of GI cancers enriched for MSI-High and TMB-High status and associated with superior outcomes following immune checkpoint inhibition. These findings support *KMT2C* as a potential predictive biomarker for immunotherapy responsiveness in gastrointestinal malignancies. Research Sponsor: Tempus.

Efficacy and circulating protein biomarkers of second-line aflibercept plus FOLFIRI according to prior bevacizumab or cetuximab treatment in advanced colorectal cancer (KCSG CO21-21). First Author: Hyunwook Kim, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: Prospective data evaluating second-line aflibercept plus FOLFIRI according to prior bevacizumab (BEV) or cetuximab (CET) exposure and incorporating circulating protein biomarkers remain limited. **Methods:** This open-label, single-arm, nationwide phase II study (NCT04810585) evaluated aflibercept plus FOLFIRI as second-line with stratification by prior BEV or CET exposure. Seventeen circulating biomarkers were measured by ELISA at baseline and before cycle 4 and analyzed for associations with PFS and OS using Cox models. Plasma proteins were processed using a single-pot solid-phase enhanced SP3 protocol followed by tryptic digestion and analyzed by data-independent acquisition liquid chromatography tandem mass spectrometry, with protein identification and quantification performed using DIA-NN. **Results:** A total of 159 patients were enrolled (prior BEV, n=83; prior CET, n=76). mPFS was 7.5 months (95% CI, 6.8–8.4), and mOS was 14.4 months (95% CI, 12.9–16.0), with no significant differences by prior biologic therapy (mOS: 13.8 vs 14.7 months for prior BEV vs CET; mPFS: 7.4 vs 7.5 months). Among 146 evaluable patients, the ORR was 28.1% (1 CR [0.7%], 40 PR [27.4%]), and the DCR was 88.4%. The most common TRAEs were proteinuria (47.1%; grade $\geq$3, 14.0%), neutropenia (43.4%; grade $\geq$3, 37.5%), nausea (27.2%), and fatigue (24.3%). Baseline PlGF (PFS HR 2.04, q=0.008; OS HR 2.86, q$<$0.001), IL-8 (PFS HR 1.87, q=0.008; OS HR 2.13, q=0.002), TIMP-1 (PFS HR 1.74, q=0.021; OS HR 3.49, q$<$0.001), and VEGF-A (PFS HR 1.74, q=0.021; OS HR 1.91, q=0.009) were independently associated with inferior PFS and OS, whereas on-treatment and C1-to-C4 biomarker ratios showed no associations. Enrichment of inflammation/immune related proteins S100A8 (log_2 FC -0.41; p=0.037) and MPO (log_2 FC -1.51; p=0.006), as well as lipid metabolism related proteins APOC3 (log_2 FC -0.58; p $<$0.001) and APOC2 (log_2 FC -0.47; p=0.003), was observed in patients with prior BEV at baseline. Enrichment of PIGR (log_2 FC -1.21; p$<$0.001) and OLFM1 (log_2 FC -0.66; p-value $<$0.001) was observed in PD patients at C4, while SERPINF1 (log_2 FC 0.33; p= 0.003) and FETUB (log_2 FC 0.41; p=0.013) were enriched in PR+CR patients at C4. Further, PIGR expression increased 1.30-fold in PD patients (mean $log_2\Delta$ (C4-C1) = 0.38), compared to a relatively stable expression in PR patients (mean $log_2\Delta$(C4-C1) = -0.076, p=0.033). Increased PIGR expression at C4 showed an association with inferior OS in Cox models (HR 1.92, p=0.004). **Conclusions:** Clinical outcomes and safety profiles of aflibercept plus FOLFIRI were comparable regardless of prior BEV or CET exposure. Elevated baseline PlGF, IL-8, TIMP-1 and VEGF-A levels were associated with shorter PFS and OS. Exploratory plasma proteomics identified dynamic PIGR expression as a response-associated biomarker linked to inferior OS. Clinical trial information: NCT04810585. Research Sponsor: Sanofi.

3567 **Poster Session**

A multicenter phase II trial of encorafenib, binimetinib, and cetuximab for early relapsed stage II/III *BRAF*^{V600E}-mutated colorectal cancer: TRESBIEN trial (OGSG 2101). First Author: Toshihiro Kudo, Department of Medical Oncology, Osaka International Cancer Institute, Osaka, Osaka, Japan

Background: Patients with *BRAF*^{V600E}-mutated colorectal cancer (CRC) who experience early recurrence during or shortly after adjuvant therapy show an extremely poor prognosis. The efficacy of BRAF-targeted triplet therapy for early relapse remains unclear. **Methods:** We conducted a prospective, open-label, multicenter, phase II trial evaluating the efficacy and safety of encorafenib, binimetinib and cetuximab in *BRAF*^{V600E}-mutated CRC patients who relapsed during or within 6 months after completing adjuvant chemotherapy. Patients received encorafenib 300 mg once daily and binimetinib 45 mg twice daily in 28-day cycles, plus intravenous cetuximab 400 mg/m^2 once on day 1 of cycle 1, then 250 mg/m^2 once weekly until disease progression or occurrence of unacceptable adverse events. The primary endpoint was objective response rate (ORR) by blinded independent central review. Secondary endpoints were overall survival (OS), progression-free survival (PFS), disease control rate (DCR), and safety. Sample size was determined based on a threshold ORR of 6.0% and an expected ORR of 26.0% (one-sided α = 0.05, power = 0.90). **Results:** Between January 2022 and April 2025, 25 patients were enrolled across 14 institutions. Baseline characteristics included: median age 68 years (range, 28–81); female, n = 18 (72.0%); right-sided, n = 18 (72.0%); pStage II/III, n = 2 (8.0%)/23 (92.0%); MSI-H, n = 5 (20.0%); and prior oxaliplatin-based adjuvant chemotherapy, n = 22 (88.0%). Twenty-four patients were evaluable for efficacy. The ORR was 62.5% (95% CI, 40.6–81.2, one-sided $P < 0.001$), and DCR was 87.5% (95% CI, 67.6–97.3). With median follow-up time of 18.0 months, the median PFS was 7.4 months (95% CI, 4.7–10.6), and the median OS was 33.9 months (95% CI, 11.0–NE). No Grade $\geq$3 adverse events ($\geq$10%) and treatment-related deaths were observed. **Conclusions:** The combination of encorafenib, binimetinib, and cetuximab demonstrated favorable efficacy and a manageable safety profile in patients with *BRAF*^{V600E}-mutated CRC who relapsed early recurrence during or shortly after adjuvant chemotherapy. This triplet regimen can be a promising treatment strategy for this poor prognostic population. Clinical trial information: jRCTs051210152. Research Sponsor: ONO PHARMACEUTICAL CO., LTD.

Clinical validation of red blood cell DNA for early detection of advanced colorectal neoplasia: A single-center prospective observational case-control clinical trial. First Author: Xingyun Yao, School of Life Sciences, Westlake University, Hangzhou, Zhejiang, China

Background: Early detection of colorectal cancer (CRC) improves survival, but current screening is limited by poor colonoscopy compliance and low cfDNA sensitivity for early-stage lesions and advanced adenomas (AA). Beyond tumor shedding, solid tumors remotely disrupt bone marrow hematopoiesis, inducing systemic genomic instability in hematopoietic lineages. Leveraging this mechanism, we developed a noninvasive detection strategy using genome-wide profiling of DNA remnants in mature red blood cells (rbcDNA). We previously showed that tumor-induced IL-18/NR4A1 signaling drives locus-specific DNA damage in hematopoietic progenitors, generating rbcDNA signatures distinct from shedding-dependent cfDNA and enabling improved detection of early-stage cancer. Here, we report the first multicenter and prospective clinical validation of this rbcDNA-based assay for the detection of early colorectal neoplasia (NCT05875584). **Methods:** We enrolled 1,251 colonoscopy-confirmed participants (561 non-advanced neoplasia controls (non-AN), 330 AA, 360 CRC). Peripheral blood (1–2 mL) was collected from each participant, and rbcDNA was isolated and sequenced by low-coverage whole-genome sequencing (~2$\times$), as previously described (PMID: 40341742). Participants were randomly assigned (8:2) to discovery and test cohorts. The discovery cohort was used for CRC- and AA-associated rbcDNA features identification and model development, while the test cohort was used for cutoff optimization. This locked model was externally validated in two independent cohorts. A prospective, observational case-control study was also conducted, in which blood and stool samples were collected simultaneously to compare the rbcDNA classifier with quantitative FIT (qFIT). Among 598 enrolled participants, 585 were included in the final analysis (299 non-AN, 206 AA, and 80 CRC). **Results:** At a predefined 90% specificity, the rbcDNA classifier achieved sensitivities of 85% for AA and 95% for CRC in the test cohort. Across two external cohorts, the assay consistently achieved 80% and 78% sensitivity for advanced colorectal neoplasia, 91% sensitivity for CRC in both cohorts, and 92% and 91% specificity. In the prospective study, rbcDNA yielded 90% sensitivity for CRC and 60% for AA at 90% specificity, with specificity remaining comparable in participants with non-neoplastic findings and non-advanced adenomas. Compared with qFIT, rbcDNA matched overall CRC sensitivity (90% vs. 88%) but outperformed it for stage I CRC (83% vs. 61%) and advanced adenomas (60% vs. 18%), including $>$50% of large sessile serrated lesions and tubular adenomas ($\geq$1 cm) versus $<$15% by qFIT. **Conclusions:** This first prospective clinical study demonstrates that rbcDNA provides a highly sensitive, non-invasive approach for early colorectal neoplasia detection. Clinical trial information: NCT05875584. Research Sponsor: Key R&D Program of Zhejiang.

SHR-A1811 plus chemotherapy and BP102 as 1L therapy for HER2-expressing mCRC: Data from a phase Ib/II study. First Author: Ting Xu, Department of Gastrointestinal Oncology, Peking University Cancer Hospital, Beijing, China

Background: HER2 expression is associated with poor prognosis in mCRC. SHR-A1811 (trastuzumab-rezetecan) is a HER2-directed ADC comprising a humanized monoclonal antibody, a cleavable tetrapeptide linker, and a topoisomerase I inhibitor payload. We evaluated the safety and preliminary efficacy of SHR-A1811 in combination with chemotherapy and BP102 (bevacizumab biosimilar) as 1L therapy for HER2-expressing mCRC. **Methods:** This open-label, multicenter phase Ib/II study (ClinicalTrials.gov: NCT06015048) used an i3+3 design in phase Ib to evaluate the safety and tolerability of SHR-A1811 + 5-FU/L-LV, $\pm$ oxaliplatin and/or BP102, and to select the phase II regimen. Phase II (proof-of-concept) assessed efficacy and safety in the 1L setting using SHR-A1811 3.2 mg/kg Q2W + 5-FU (300 mg/m^2 IV bolus, 1800 mg/m^2 continuous infusion over 46–48 h Q2W) + L-LV 200 mg/m^2 IV Q2W + BP102 5 mg/kg IV Q2W $\pm$ oxaliplatin 60 mg/m^2 IV Q2W. Tumor response was assessed per RECIST v1.1, and AEs were evaluated per CTCAE v5.0. **Results:** As of Dec 31, 2025 (data cutoff), 39 pts received SHR-A1811 + FOLFOX (-1) + BP102, and 11 pts received SHR-A1811 + 5-FU/L-LV + BP102. All were Asian with *pMMR/MSS* and *BRAF* wild-type disease. The median age was 58 (range, 30–71) and 57 (range, 42–72), respectively. 28/39 (71.8%) and 7/11 (63.6%) were male. ECOG PS was 1 in 24/39 (61.5%) and 6/11 (54.5%). HER2 positivity (IHC 3+ or IHC 2+/ISH+) was observed in 21/39 (53.8%) and 5/11 (45.5%). HER2 IHC 2+/ISH$-$ was observed in 18/39 (46.2%) and 5/11 (45.5%). Liver metastases were present in 28/39 (71.8%) and 4/11 (36.4%). 15/39 (38.5%) and 5/11 (45.5%) had *RAS* mutations. Median follow-up was 10.4 m (range, 6.1–17.0) and 11.9 m (range, 3.3–19.0). ORR was 74.4% (29/39; 95% CI, 57.9–87.0) and 40.0% (4/10; 95% CI, 12.2–73.8). DCR was 97.4% (38/39; 95% CI, 86.5–99.9) and 90.0% (9/10; 95% CI, 55.5–99.8). mPFS was 15.6 m (95% CI, 11.3–NR) and 9.6 m (95% CI, 1.8–NR). In HER2 positive pts received SHR-A1811 + mFOLFOX6(-1) + BP102, ORR was 90.5% (19/21; 95% CI, 69.6-98.8), DCR was 100% (21/21; 95% CI, 83.9-100), 9m-PFS rate was 94.7% (95% CI, 68.1-99.2); among HER2 positive *RAS* mutant/wild type subgroups, 9m-PFS rate was 83.3% (95%CI, 27.3-97.5) and 100%. OS was immature. Grade $\geq$3 TRAEs occurred in 31/39 (79.5%) and 6/11 (54.5%) in the two cohorts, with the most common being decreased neutrophil count (56.4% vs 18.2%), decreased white blood cell count (17.9% vs 18.2%), anemia (12.8% vs 9.1%), and stomatitis (12.8% vs 0). TRAEs led to discontinuation of any drug in 4/39 (10.3%) (SHR-A1811: 1; chemo: 1; BP102: 3) and in none. TRAEs led to dose reductions in 12/39 (30.8%) and 3/11 (27.3%) (SHR-A1811: 3 vs 1; chemo: 11 vs 3). No TRAE-related deaths occurred. **Conclusions:** SHR-A1811 plus chemotherapy and BP102 as 1L therapy for HER2 intermediate or high-expressing mCRC demonstrated manageable safety and encouraging antitumor activity. Clinical trial information: NCT06015048. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

A transcriptomic signature to predict immune checkpoint inhibition efficacy in proficient mismatch repair metastatic colorectal cancer: Translational analysis of the AVETRIC and TRIPLETE studies. First Author: Martina Carullo, Unit of Medical Oncology 2, Azienda Ospedaliera Universitaria Pisana and Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy

Background: ICIs provide limited benefit in proficient mismatch repair (pMMR) metastatic colorectal cancer (mCRC), highlighting the need for predictive biomarkers. We aimed to uncover transcriptomic profiles predictive of ICI efficacy, using tumor specimens from two matched cohorts of pMMR, *RAS/BRAF* wild-type (wt) mCRC patients (pts) enrolled in two academic clinical trials investigating first-line FOLFOXIRI plus an anti-EGFR agent ± ICI. **Methods:** The phase II AVETRIC study (NCT04513951) provided the ICI-treated cohort (mFOLFOXIRI/anti-EGFR plus avelumab), while the experimental arm of the phase III TRIPLETE study (NCT03231722) served as the ICI-untreated control cohort (mFOLFOXIRI/anti-EGFR). Bulk RNA-seq analysis was performed using the Signomax platform on naive tumor specimens of 39 and 32 pts from the ICI and control cohorts, respectively. Firstly, gene set variation (GSV) analyses compared extended PFS (e-PFS) versus limited PFS (l-PFS) groups (using median PFS of the control cohort as a cut-off) within each cohort, leading to a focus on immune- and EGFR-related pathways. Secondly, using the median immune- and EGFR-related pathway scores in the ICI cohort as a cut-off, samples were classified combining both pathway activities into an immune^{high}-EGFR^{high} group versus a pooled group comprising all the other cases (immune-EGFR^{others}). Associations with PFS and OS were assessed by treatment cohort. **Results:** Thirty-four (87%) (23 e-PFS, 11 l-PFS) and 26 (81%) (13 e-PFS, 13 l-PFS) samples were successfully analyzed in the ICI and control cohorts, respectively. In the ICI cohort, l-PFS samples showed lower activity of both immune- and EGFR-related pathways than e-PFS ones, while no significant differences in the activation of the same pathways were observed between PFS groups in the control cohort. Additionally, 29 pts were classified as immune^{high}-EGFR^{high} (13 [45%] and 16 [55%] in the ICI and control cohorts, respectively) and 31 pts as immune-EGFR^{others} (21 [68%] and 10 [32%] in the ICI and control cohorts, respectively). Immune^{high}-EGFR^{high} pts reported longer PFS (HR: 0.57, 95% CI 0.33-0.98, *P*=0.04) and OS (HR: 0.66, 95% CI 0.36-1.24, *P*=0.20) than other pts. Borderline significant interaction between treatment and immune/EGFR signature was found in PFS (*P*=0.145) with ICI benefit restricted to pts bearing the immune^{high}-EGFR^{high} signature (HR PFS: 0.56, 95% CI 0.25-1.24, versus 1.25, 95% CI 0.60-2.64 in the others). **Conclusions:** Exploratory transcriptomic profiling may identify a subset of pMMR *RAS/BRAF* wt mCRC with concurrent immune activation and EGFR dependency that could benefit from combining ICI to an intensified anti-EGFR-based first-line treatment. A phase II combination study of galunisertib and capecitabine in patients with chemotherapy-resistant colorectal cancer with peritoneal metastases. First Author: Ashwini Kanhailal, Antoni van Leeuwenhoek Hospital - Netherlands Cancer Institute, Amsterdam, Netherlands

Background: Transforming growth factor β (TGF-β) plays a dynamic role in cancer biology. It acts as a tumor suppressor in early stages of tumor development. Certain tumor types, such as colorectal cancer (CRC), exploit this signaling route to induce pathways that promote tumor growth, enhancing the tumor's aggressiveness. CRC of the mesenchymal subtype exhibits prominent TGF-β activation, contributing to drug resistance, including to 5-fluorouracil (5-FU)-based chemotherapy. This subtype is found in most CRC patients with peritoneal metastases. Therefore, combining TGF-β inhibition with chemotherapy could be a beneficial approach to overcome resistance. **Methods:** This two-center, open-label, non-randomized proof-of-principle phase II study with a safety lead-in involved combining TGF-β inhibitor galunisertib (150 mg twice daily) with capecitabine (1000 mg/m^2 twice daily) for 14 days in a 28-day cycle. Adult patients with histologically or cytologically proven CRC and confirmed peritoneal metastases were eligible for inclusion if they were in a good clinical condition, had exhausted all their treatment options, and had no gastrointestinal impaired function. In the safety lead-in phase, six patients were evaluated for safety and tolerability, as assessed by the incidence of dose limiting toxicities (DLTs) and adverse events. Phase II followed a Simon two stage design with progression to the second stage when ≥2 objective tumor responses out of 15 patients were reached. Secondary objectives included pharmacokinetics (PK) and pharmacodynamics (e.g. TGF-β expression, immunohistochemical staining for phosphorylated SMAD2/3). **Results:** As of January 23 2026, inclusion was closed, after 22 patients were recruited. 54% of patients were female, with a median age of 60 years (38-77). No DLTs were observed in 21 DLT-evaluable patients. Only grade 1/2 treatment-related adverse events occurred. The most common events were nausea (23%), hypophosphatemia (18%), and fatigue (18%). No objective responses were observed. Four of 20 patients evaluable for efficacy showed stable disease with a median duration of 4 months. PK analysis of patients in the safety lead-in showed high interpatient variability for galunisertib, capecitabine and 5-FU (CV% $AUC_{(0\text{-}12)}$: between 54%-70%). Galunisertib did not show drug accumulation over time ($AUC_{(0\text{-}12)}$ on cycle 1 day 1 and $AUC_{(0\text{-}12)}$ on cycle 1 day 14 were 7.6 and 6.6 μg*h/mL, respectively). The PK of capecitabine and 5-FU were similar to those described in the literature. Pharmacodynamic analyses are ongoing. **Conclusions:** The combination of galunisertib and capecitabine did not result in objective responses or long term stable disease in chemotherapy-resistant CRC patients with peritoneal metastases. The treatment was well tolerated and PK results for both compounds were similar to those described in the literature. Clinical trial information: NCT05700656. Research Sponsor: None.

Circulating tumor DNA (ctDNA) tumor fraction (TF) dynamics to refine progression-free survival and radiographic response during anti-EGFR rechallenge in metastatic colorectal cancer. First Author: Guglielmo Vetere, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Reliable biomarkers of benefit from anti-EGFR rechallenge are needed in anti-EGFR-refractory metastatic colorectal cancer (mCRC), where prior studies have shown modest progression-free survival (PFS) and radiographic response may incompletely capture biological sensitivity. We evaluated longitudinal ctDNA dynamics as a real-time biomarker of treatment effect. **Methods:** This analysis was conducted within a phase II enrichment study of panitumumab with or without trametinib in anti-EGFR-refractory mCRC; crossover was allowed after progression on monotherapy. Plasma was collected at baseline, prior to each infusion, and at progression or end of treatment. Patients with a baseline and ≥ 1 subsequent on-treatment sample were evaluable. ctDNA TF was estimated with the Guardant Reveal assay by normalizing cancer-specific differentially methylated regions with matched controls in each sample. In samples with detectable ctDNA, Guardant360 Liquid was used for genotyping of > 700 genes and tumor mutational burden (TMB). ctDNA TF dynamics were defined by best % change from baseline. Baseline TF, TMB, and focal amplifications in the MAPK pathway were also evaluated. PFS was the primary endpoint and best radiographic response (RECIST 1.1) was the secondary endpoint. Differences were assessed using Kaplan-Meier analyses, Cox proportional hazards models adjusted by age, sex, line of therapy, and treatment regimen, and the Kruskal-Wallis test. **Results:** A total of 38 patients were included. Consistent with the advanced clinical setting, median TF at baseline was 11.9%. Following adjusted Cox modeling, baseline ctDNA TF was prognostic when dichotomized at 2% (median PFS (mPFS): 3.55 vs 1.97 months, HR 0.32, 95% CI 0.13-0.77), whereas baseline TMB and focal amplifications in the MAPK pathway were not associated with PFS. ctDNA TF % change from baseline to best on-treatment value was strongly associated with PFS in patients with any decrease vs no decrease (mPFS: 3.16 vs 1.77 months, HR 0.24, 95% CI 0.08-0.69, p = 0.008), and the longest PFS was observed in patients achieving ≥ 80% TF decrease vs all others (mPFS: 3.61 vs 1.87 months, HR 0.20, 95% CI 0.08-0.49, $p < 0.005$). Median best TF % change was -31%, -80%, and -96% for PD, SD, and PR, respectively ($p < 0.001$). Among patients achieving SD or PR, 100% had any TF decrease and 61% had a > 80% TF decrease, while in patients with PD as best response, 74% had any TF decrease and 5% had a > 80% TF decrease. No impact of ctDNA-related variables was observed in the crossover setting. **Conclusions:** ctDNA TF dynamics are strongly associated with PFS and provide clinically meaningful information beyond conventional imaging in mCRC patients undergoing anti-EGFR rechallenge, highlighting ctDNA TF as a powerful tool for refining response assessment and personalizing treatment decisions. ctDNA dynamics and prognostic value during first-line treatment of metastatic colorectal cancer: Analysis from the phase 3 PARADIGM study. First Author: Kentaro Yamazaki, Division of Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan

Background: The phase 3 PARADIGM trial showed overall survival (OS) and tumor response advantages of anti-EGFR (panitumumab, PAN) over anti-VEGF (bevacizumab, BEV) therapy with FOLFOX6 in first-line metastatic colorectal cancer (mCRC) despite similar progression-free survival (PFS), highlighting limitations of imaging-based PFS as a surrogate for clinical benefit. We investigated whether ctDNA dynamics provide more refined prognostic information complementary to baseline (BL) ctDNA. **Methods:** Plasma samples collected from 556 patients (pts) with mCRC paired at pre-treatment (BL) and post-treatment (after treatment discontinuation) were profiled for ctDNA. Distribution of the highest variant allele fraction was modeled using a Gaussian mixture model. At pre- and post-treatment, pts were classified into 3 groups—High, Mid, and Low—according to ctDNA levels. OS, post-treatment survival (PTS), and PFS were compared across 9 ctDNA dynamic categories (eg, High→Low, High→Mid, High→High) based on changes from pre- to post-treatment. **Results:** Lower BL ctDNA was significantly associated with longer OS (median OS [95% CI]: Low, n = 97, 50.7 mo [44.0–65.2]; Mid, n = 159, 34.1 mo [26.9–37.1]; High, n = 300, 27.8 mo [26.2–31.3]). BL ctDNA level also correlated with tumor volume and mutation burden. Pts with lower ctDNA at treatment discontinuation had longer PTS. Incorporating ctDNA dynamics provided additional prognostic value. Regardless of BL ctDNA level, pts whose post-treatment ctDNA decreased to Low had the best survival (eg, High→Low: 50.9 mo [35.8–61.0]), while pts with persistently high ctDNA showed the poorest survival (High→High: 23.3 mo [18.2–27.8]). The prognostic value of ctDNA dynamics was consistent across treatment arms. Among pts with High BL ctDNA (PAN, n = 152; BEV, n = 148), a greater proportion achieved Low ctDNA at post-treatment with PAN vs BEV (29 [19.1%] vs 16 [10.8%], p = 0.053), whereas the proportions achieving Mid ctDNA were similar (52 [34.2%] vs 58 [39.2%], p = 0.40). In the High→Low/Mid ctDNA subsets, treatment discontinuation following curative resection was more frequent with PAN vs BEV (High→Low: 18/29 [62.1%] vs 7/16 [43.8%]; High→Mid: 11/52 [21.2%] vs 5/58 [8.6%]). OS and PTS trends were favorable with PAN vs BEV (OS; High→Low: 61.0 vs 43.1 mo, HR 0.49, 95% CI 0.23–1.04; High→Mid: 33.6 vs 26.8 mo, HR 0.74, 95% CI 0.50–1.11, PTS; High→Low: 55.1 vs 39.0 mo, HR 0.48, 95% CI 0.22–1.03; High→Mid: 20.6 vs 19.4 mo, HR 0.72, 95% CI 0.48–1.07). **Conclusions:** ctDNA dynamics add prognostic value beyond BL ctDNA level. In pts with high BL ctDNA, PAN yielded more conversions into low ctDNA levels and discontinuations following curative resection, with OS/PTS trends favoring PAN. These findings suggest that ctDNA dynamics may better reflect long-term clinical benefit than PFS, although standardized thresholds and prospective validation are needed. Clinical trial information: NCT02394834; NCT02394795. Research Sponsor: Takeda Pharmaceutical Company Limited.

Contribution of atezolizumab (atezo) to the efficacy of the zanzalintinib (zanza) + atezo combination in patients (pts) with previously treated metastatic colorectal cancer (mCRC): Evidence from the phase 3 STELLAR-303 trial. First Author: Anees Dauki, Exelixis, Inc., Alameda, CA

Background: Outcomes remain poor for pts with previously treated mCRC, the vast majority of whom have tumors that are not microsatellite instability-high or mismatch repair deficient. Zanza is a novel, small molecule inhibitor of multiple kinases, including TAM kinases (TYRO3, AXL, and MER), MET, and VEGF receptors, which play important roles in oncogenic processes, including immune suppression in the tumor microenvironment. In STELLAR-303, zanza + atezo significantly improved overall survival (OS) versus regorafenib (rego) in pts with previously treated mCRC. The objective here was to assess the contribution of atezo to the efficacy of the zanza + atezo combination. **Methods:** The effect of atezo immunogenicity on efficacy was evaluated by comparing progression-free survival (PFS) and OS between atezo treatment-emergent anti-drug antibody (TEADA)-positive and TEADA-negative pts. Unstratified Cox proportional hazards regression models were used to estimate HRs for TEADA subgroups relative to the rego arm. Exposure-response (ER) analyses examined the relationship between atezo serum trough concentrations and efficacy endpoints using Cox proportional hazards models. **Results:** Of 451 pts randomized to zanza + atezo, 394 were evaluable for atezo TEADAs (TEADA-positive at any post-baseline visit, n = 143; TEADA-negative, n = 251). Baseline clinical characteristics and key prognostic factors (eg, *RAS* status, geographic region, presence of liver metastasis, location of primary tumor) were well balanced between TEADA subgroups, minimizing potential confounding due to subpopulation differences. Relative to the rego arm (n = 450), HRs (95% CI) favored zanza + atezo for PFS across both TEADA-positive (0.81 [0.67–0.99]) and TEADA-negative (0.59 [0.51–0.71]) subgroups. Similar results were observed for OS in the TEADA-positive (0.79 [0.63–0.98]) and TEADA-negative (0.72 [0.60–0.86]) subgroups. The greatest benefit for both PFS and OS was in the TEADA-negative subgroup. Based on ER analyses (n = 376), there was a statistically significant ($p < 0.001$) relationship between time-varying atezo trough concentrations and efficacy endpoints—estimated HRs (95% CI) comparing the 95th with the 5th percentiles of atezo trough concentrations were 0.82 (0.80–0.83) for PFS and 0.73 (0.70–0.75) for OS. Safety profiles were comparable between TEADA-positive and TEADA-negative pts. **Conclusions:** Zanza + atezo demonstrated PFS and OS benefit regardless of atezo TEADA status, with greater efficacy observed in TEADA-negative pts. ER analyses showed that higher atezo serum trough concentrations were associated with longer PFS and OS. These results support the contribution of atezo to the survival benefits observed with the zanza + atezo combination in pts with mCRC in the STELLAR-303 trial. Clinical trial information: NCT05425940. Research Sponsor: Exelixis, Inc.

FIRE-4 (AIO KRK-0114): Efficacy of third-line rechallenge with cetuximab versus investigator's choice in relation to the interval between initial and third-line anti-EGFR therapy. First Author: Lena Weiss, Department of Medicine III, University Hospital Munich LMU, Munich, Germany

Background: The randomized FIRE-4 study evaluated the effect of cetuximab rechallenge versus investigator's choice in the 3rd-line treatment of patients (pts) with RAS-wildtype (RAS-wt) metastatic colorectal cancer (mCRC). The present analysis focuses on the time between the end of initial anti-EGFR-based treatment and start of 3rd-line therapy (TIS-3) as a potential predictor of response. **Methods:** In FIRE-4, all pts received induction therapy with FOLFIRI plus cetuximab. After 1st PD, an anti-EGFR-free "window therapy" was recommended. At diagnosis of 2nd PD, pts who had responded to induction therapy were re-evaluated for RAS status and, after exclusion of RAS mutations, were offered randomization to either rechallenge with cetuximab plus chemotherapy or investigator's choice. Overall survival in 3rd-line (OS-3) was evaluated as a primary endpoint. **Results:** Of the 87 pts entering 3rd-line treatment in FIRE-4, 45 received (FOLF)IRI plus cetuximab (rechallenge arm), and 42 received investigator's choice (standard arm). Numerically superior outcome parameters regarding ORR-3 (OR 2.70), PFS-3 (HR 0.87) and OS-3 (HR 0.86) were observed in the rechallenge arm, without, however, reaching the level of statistical significance. To evaluate the relevance of TIS-3, we focused on the median (13.8 months) and the first quartile (9.0 months). Based on these cut-off values, treatment effects were evaluated in pts with longer and shorter TIS-3 intervals (see Table). **Conclusions:** Longer TIS-3 intervals were associated with longer survival times in 3rd-line treatment. This observation was particularly true for pts receiving cetuximab rechallenge, but also for those receiving investigator's choice. Clinical trial information: NCT02934529. Research Sponsor: None.

Treatment arm	N	Interval	PFS (mo)	HR	OS (mo)	HR
FOLF(IRI) + Cetuximab	21	> 13.8 mo	7.4	0.475	20.0	0.639

Ivonescimab (ivo) with oxaliplatin + fluorouracil (5-FU) + leucovorin calcium (mFOLFOX6) for patients (pts) with unresectable metastatic colorectal cancer (mCRC): A phase 2 study. First Author: David Berz, Department of Oncology, Valkyrie Clinical Trials, Inc, Los Angeles, CA

Background: Ivonescimab is an investigational tetrameric bispecific antibody targeting both programmed death protein 1 and vascular endothelial growth factor that demonstrated efficacy and a tolerable safety profile in multiple phase 3 studies in pts with non-small cell lung cancer, and is being investigated in other solid tumor types. This multi-part phase 2 study (NCT05382442) evaluated ivo + chemotherapy as first-line treatment of mCRC. Here, we report interim results from the multiregional regimen extension phase of the study, which evaluated ivo 20 or 10 mg/kg + mFOLFOX6. **Methods:** Adult pts (≥18 years) in China and the US with confirmed mCRC who had an Eastern Cooperative Oncology Group score of 0-1, were not candidates for radical surgical resection or local therapy, and had not received systemic anti-tumor therapy in the recurrent or metastatic stage were enrolled; pts who received prior neoadjuvant or adjuvant therapy were permitted if first recurrence/metastasis occurred ≥12 months (mo) after the last dose. Pts were randomly assigned 1:1 to receive intravenous ivo (20 mg/kg or 10 mg/kg) + mFOLFOX6 once every 2 weeks for up to 8 cycles, followed by maintenance with 5-FU + ivo until disease progression, intolerable toxicity, or withdrawal of consent for up to 2 years. The primary endpoints were objective response rate (ORR; assessed by Response Evaluation Criteria in Solid Tumors v1.1) and incidence and severity of treatment-emergent adverse events (TEAEs). Secondary efficacy endpoints included disease control rate (DCR) and progression-free survival (PFS). **Results:** At the time of data cutoff for this interim analysis (December 31, 2025), 49 pts were enrolled (ivo 20 mg/kg + mFOLFOX6, n = 25; ivo 10 mg/kg + mFOLFOX6, n = 24) with an overall median age of 58 years; 79.6% of pts had left-sided tumors, 53.1% had *KRAS* or *BRAF* tumor mutations, and 67.3% had liver metastases. Median follow-up was 7.5 mo (range, 3.5-10.3) and 7.1 mo (range, 1.9-10.3) in the ivo 20 mg/kg + mFOLFOX6 and ivo 10 mg/kg + mFOLFOX6 arms, respectively. ORR was 70.8% in each treatment arm; all were partial responses. DCR was 100% in each treatment arm. Median PFS was not reached. PFS rate at 6 months was 95.2% and 84.8% in the ivo 20 mg/kg + mFOLFOX6 and ivo 10 mg/kg + mFOLFOX6 arms, respectively. Grade ≥3 TEAEs related to ivo occurred in 40.0% and 33.3% of patients in the ivo 20 mg/kg + mFOLFOX6 and ivo 10 mg/kg + mFOLFOX6 arms, respectively, and serious TEAEs related to ivo were reported in 24.0% and 16.7% of pts, respectively. TEAEs led to discontinuation of ivo in 4.0% in the ivo 20 mg/kg + mFOLFOX6 arm and in 0% in the ivo 10 mg/kg + mFOLFOX6 arm. No TEAEs led to death. **Conclusions:** With 7.3 mo follow-up, ivo + mFOLFOX6 showed encouraging efficacy and a manageable safety profile in pts with untreated mCRC. Clinical trial information: NCT05382442. Research Sponsor: Summit Therapeutics, Inc.

3577 **Poster Session**

Cadonilimab, a bispecific anti–PD-1/CTLA-4 antibody, for patients with dMMR/MSI-H metastatic colorectal cancer after progression on anti–PD-(L)1 therapy: A multicenter, single-arm, phase 2 trial (CSWOG-C03). First Author: Huabin Hu, Department of Medical Oncology, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Immune checkpoint blockade targeting PD-1 is the standard of care for patients with mismatch repair–deficient or microsatellite instability–high (dMMR/MSI-H) metastatic colorectal cancer (mCRC). However, approximately 37%–45% of patients experience disease progression within 1 year when treated with anti-PD-1 monotherapy, and effective subsequent treatment options remain undefined. The CSWOG-C03 study evaluated the efficacy and safety of cadonilimab, a bispecific anti-PD-1/CTLA-4 antibody, in patients with dMMR/MSI-H mCRC after progression on prior anti-PD-(L)1 therapy. **Methods:** This multicenter, single-arm, phase 2 study enrolled patients with centrally confirmed dMMR/MSI-H mCRC and iRECIST-defined disease progression after prior anti-PD-(L)1 monotherapy or anti-PD-(L)1-based combination therapy. Patients received intravenous cadonilimab at 6 mg/kg every 2 weeks until disease progression or unacceptable toxicity. The primary endpoint was the 12-month progression-free survival (PFS) rate, assessed by RECIST v1.1. **Results:** A total of 24 patients were enrolled and received study treatment. The median age was 54 years; 29% were female, 17% had Lynch syndrome, 92% had peritoneal metastases, and 33% had liver metastases. Overall, 63% of patients had received ≥2 prior lines of systemic therapy; all had prior exposure to anti-PD-(L)1 therapy, 71% had received fluoropyrimidines and oxaliplatin, and 29% had received irinotecan. The best response to prior anti-PD-(L)1 therapy was partial response in 2 patients, stable disease in 17, and progressive disease in 5. With a median follow-up of 14.8 months at data cutoff (January 22, 2026), the 12-month PFS rate was 44.6% (95% CI, 23.4–63.9), meeting the prespecified primary endpoint of 40%. Median PFS was 6.1 months (95% CI, 2.2–10.1). Median overall survival (OS) was not reached and the 12-month OS rate was 68.6% (95% CI, 42.5–84.7). The confirmed objective response rate (ORR) was 20.8% (95% CI, 7.1–42.2), and the disease control rate (DCR) was 75.0% (95% CI, 53.3–90.2). One patient completed the protocol-specified 2-year treatment without progression, and 7 remained on study treatment. Treatment-related adverse events of any grade occurred in 15 patients (63%), with grade 3 events observed in 3 patients (13%). **Conclusions:** Cadonilimab provided meaningful disease control with modest antitumor activity and a manageable safety profile in patients with dMMR/MSI-H mCRC after progression on prior anti-PD-(L)1 therapy. Clinical trial information: NCT05426005. Research Sponsor: National Science Fund for Distinguished Young Scholars; 82425045.

Radiotherapy followed by systemic therapy and tislelizumab in microsatellite-stable rectal cancer with synchronous unresectable metastases: Updated results of the MIRACLE-2 study. First Author: Menglong Zhou, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Microsatellite-stable (MSS) tumors comprise ~95% of metastatic colorectal cancer cases and exhibit intrinsic resistance to immunotherapy. Emerging evidence suggests systemic therapy may enhance immunotherapy responsiveness, while radiotherapy could improve efficacy by overcoming resistance and reducing tumor burden. The MIRACLE-2 study evaluated the safety and efficacy of combining radiotherapy with systemic therapy and tislelizumab as first-line treatment for unresectable metastatic MSS rectal cancer (RC). **Methods:** MIRACLE-2 was a prospective, single-arm, phase II study. Inclusion criteria: MSS RC with primary tumor ≤10 cm from anal verge on MRI and synchronous unresectable metastases. Patients received hypofractionated radiotherapy (HFRT) for primary lesions and HFRT or SBRT for metastases, followed by systemic therapy: FOLFOX-bevacizumab-tislelizumab for RAS/BRAF-mutant patients or FOLFIRI-cetuximab-tislelizumab for wild-type patients. Reassessment every 8 weeks. Patients achieving resectable disease underwent primary tumor resection and metastasectomy/local ablative therapies for metastases. For patients unable to preserve anal sphincter, a watch-and-wait (WW) strategy was considered if clinical complete response (cCR) of primary tumor was achieved. Otherwise, systemic therapy continued until progression/intolerable toxicity. Primary endpoint: ETS rate (≥20% target lesion reduction at 8 weeks post systemic therapy initiation). Secondary endpoints: disease control rate (DCR), duration of response (DOR), overall survival (OS), progression-free survival (PFS), and safety. **Results:** As of December 31, 2025, efficacy data were available for 50 patients (38 males, 76.0%; median age 57 years, range 30-73). Among these, 52.0% had liver metastases, 8.0% lung metastases, and 40.0% both liver and lung metastases. RAS/BRAF mutations were detected in 56.0% of primary tumors. Median treatment courses: eight (range 3-12). Overall, 18% (9/50) attained no evidence of disease (NED). ETS rate: 76.0%; DCR: 88.0%. Median follow-up: 19.9 months (95% CI: 16.4-23.4). Among 34 patients with complete/partial response, median DOR: 8.0 months (95% CI: 5.2–10.8), with 1-year DOR rate of 20%. Median PFS: 9.3 months (95% CI: 7.1-11.5), with 1-year PFS rate of 33.4%. Median OS: 23.2 months (95% CI: 15.1-31.3), and 1-year OS rate: 93.3%. No grade 5 treatment-related adverse events (TRAEs) occurred. All-grade TRAEs: lymphopenia (95.9%), anemia (91.8%), and leukopenia (69.4%). Grade 3/4 TRAEs: lymphopenia (36.7%), neutropenia (26.5%), and leukopenia (20.4%). **Conclusions:** The combination of radiotherapy, systemic therapy, and tislelizumab showed a high ETS rate and manageable safety profile in first-line unresectable MSS RC. Long-term outcomes require further follow-up. Clinical trial information: NCT05359406. Research Sponsor: None.

Indirect comparison of nivolumab-ipilimumab versus chemotherapy (Chemo) and/or immunotherapy in dMMR/MSI-H metastatic colorectal cancer (mCRC) using reconstructed individual patient data (IPD). First Author: Daniele Rossini, Department of Experimental and Clinical Medicine, University of Florence; Oncology Unit, Careggi University Hospital, Florence, Italy

Background: In patients with dMMR/MSI-H mCRC, phase III randomized trials have established immune checkpoint (IO) inhibition as a key first-line strategy. In KEYNOTE-177, pembrolizumab demonstrated superior outcomes vs chemo, supporting an IO-first approach. In CheckMate 8HW, nivolumab plus ipilimumab (Nivo+Ipi) outperformed both nivolumab and chemo, demonstrating benefit from dual checkpoint blockade. In contrast, COMMIT evaluated FOLFOX plus bevacizumab plus atezolizumab and reported improved outcomes vs atezolizumab monotherapy. Despite these advances, a direct head-to-head comparison between Nivo+Ipi and chemo-IO remains unavailable. We addressed this unmet question by reconstructing IPD from published Kaplan-Meier (KM) curves to enable an indirect cross trial comparison. **Methods:** Published PFS KM curves were digitized to pseudo-IPD. To mitigate cross-trial differences, arms were divided into four groups: Nivo+Ipi (CheckMate 8HW; n=171), chemo-IO (COMMIT; n=38), IO monotherapy [pembrolizumab (KEYNOTE-177; n=153), nivolumab (CheckMate 8HW; n=170), atezolizumab (COMMIT; n=40); n=363], and chemo (standard arms in KEYNOTE-177/CheckMate 8HW; n=238). The primary estimand was PFS restricted mean survival time (RMST) at τ=24 months. As a late-benefit sensitivity analysis, RMST was also estimated at τ=48 months where ≥10% patients remained at risk, to limit instability from sparse tails. KM comparisons (log-rank and Cox HR) were derived from reconstructed pseudo-IPD. **Results:** At τ=24 months, Nivo+Ipi improved PFS RMST vs chemo (18.87 vs 10.33 months; ΔRMST +8.54, 95% CI 6.78-10.31; p<0.001) and vs IO monotherapy (18.87 vs 14.61 months; ΔRMST +4.26, 95% CI 2.54-5.99; p<0.001). Chemo-IO improved RMST vs chemo (16.92 vs 10.33 months; ΔRMST +6.59, 95% CI 3.59-9.60; p<0.001). In the key indirect comparison, Nivo+Ipi vs chemo-IO did not show a statistically significant RMST difference (18.87 vs 16.92 months; ΔRMST +1.95, 95% CI -1.14-5.04; p=0.217). In contrast, the late-benefit (τ=48 months) analysis demonstrated a statistically significant advantage for Nivo+Ipi (RMST 35.00 vs 27.71 months; ΔRMST +7.29, 95% CI 0.08-14.49; p=0.048). KM-derived estimates were consistent with these patterns: Nivo+Ipi outperformed chemo (p<0.001) and IO monotherapy (p<0.001), and chemo-IO outperformed chemo (p<0.001). Compared with chemo-IO, Nivo+Ipi was associated with numerically longer PFS (NE vs 30.2 months; HR 0.62, 95% CI 0.36-1.05; p=0.073). **Conclusions:** Nivo+Ipi and chemo IO substantially improved 24-month PFS RMST vs chemo and IO monotherapy, with similar outcomes. Nivo+Ipi showed a significant advantage over chemo-IO at 48 months, consistent with a sustained late PFS effect. Findings are hypothesis-generating given cross-trial heterogeneity and reconstruction-related bias. Research Sponsor: None.

Avatrombopag for chemotherapy-induced thrombocytopenia in gastrointestinal malignancies (ACT-GI): A multicenter, U.S., randomized, double-blind, placebo-controlled clinical trial. First Author: Gerald A. Soff, University of Miami Health System/Sylvester Comprehensive Cancer Center, Miami, FL

Background: Chemotherapy-induced thrombocytopenia (CIT) is a frequent complication of chemotherapy. Persistent CIT (not adequately resolved by day 1 of the following cycle) may lead to reduction or delay in treatment. There are no FDA approved therapies for CIT. Aim: To evaluate the safety and efficacy of avatrombopag (AVA), an oral thrombopoietin receptor agonist, to treat persistent CIT and prevent its recurrence in GI cancer. **Methods:** ACT-GI (NCT05772546) was a multicenter, randomized, double-blind, placebo-controlled, investigator-initiated trial of GI cancer patients with persistent CIT (platelets [Plt] $<85\times10^9$/L on day 1 of a scheduled chemotherapy cycle). Patients were randomized 1:1 to AVA 40 mg daily or placebo and treated for two on-study phases. In the lead-in phase, patients were treated up to 2 weeks while chemotherapy was held. Patients proceeded to the on-cycle phase and resumed chemotherapy only if their Plt recovered to $\geq100\times10^9$/L. In the on-cycle phase, patients received a single full-dose chemotherapy cycle with continued study drug. The primary endpoint was successful correction of CIT and prevention of recurrence (achieving Plt $\geq100\times10^9$/L within the lead-in period AND prevention of CIT recurrence (Plt $\geq100\times10^9$/L) at end of the cycle). **Results:** Efficacy: ACT-GI was closed to enrollment by the DSMB, for overwhelming efficacy, at a prespecified interim analysis when 20 patients in each arm completed the double-blind period. 16 of 23 patients (70%; 95% CI 47% to 87%) in the AVA arm achieved the primary endpoint versus 4/24 patients (17%; 95% CI 5% to 37%) in the placebo arm (Z=3.67, P<0.001). 74% and 88% of patients had stage IV cancer in AVA and placebo arms, respectively. 44/47 patients completed study drug; 2 discontinuations were due to physician decision and 1 was due to an adverse event. Plt improvement to $\geq100\times10^9$/L during lead-in was achieved by 83% of patients in the AVA arm vs. 46% of patients in the placebo arm. The median (IQR) Plt at the end of the on-cycle treatment period was 157 (136-202) in the AVA arm vs 72 (68-134) in the placebo arm. In the AVA arm there were two clinically relevant bleeding events (intestinal stoma site bleed at Plt 105×10^9/L and intracranial hemorrhage). No patient received platelet transfusion. Safety: AEs and serious AEs (SAEs) occurred in 74% and 13% of patients in the AVA arm and 46% and 0% of patients in the placebo arm, respectively. No SAEs were study drug-related. There were no treatment-related AEs leading to death or discontinuation of study drug. **Conclusions:** In this randomized, placebo-controlled trial, AVA demonstrated safety, tolerability, and efficacy in treatment and prevention of persistent CIT in GI cancers. These findings are promising for a common, serious condition that prevents delivery of full-dose, on-time cancer-directed therapy. Clinical trial information: NCT05772546. Research Sponsor: Swedish Orphan Biovitrum (Sobi).

3581 **Poster Session**

Propensity score–matched analysis of trifluridine-tipiracil plus bevacizumab (FTD/TPI+Bev) vs anti-EGFR re-treatment in pretreated metastatic colorectal cancer (mCRC). First Author: Giovanni Trovato, Oncologia Medica, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli, IRCCS Università Cattolica del Sacro Cuore, Rome, Italy

Background: The SUNLIGHT trial established FTD/TPI+Bev as a preferred 3rd-line option for unselected mCRC patients (pts). Recently, the phase II randomized PARERE trial reported high response rates and favorable progression-free survival (PFS) with anti-EGFR re-treatment in *RAS/BRAF* wild-type (wt) mCRC pts selected by liquid biopsy versus regorafenib. In the absence of head-to-head comparisons between these two strategies, we performed an indirect analysis, using propensity score matching (PSM) to minimize baseline imbalances. **Methods:** Two cohorts of pretreated (≥2 previous lines) mCRC pts were compared: pts with *RAS/BRAF* wt tumors receiving FTD/TPI+Bev enrolled in the Italian real-world FLOWER trial, and *RAS/BRAF* wt pts at the liquid biopsy enrolled in Arm A (panitumumab (Pan) re-treatment followed by regorafenib) of the PARERE trial. PSM was applied adjusting for age, sex, ECOG performance status, number (N) of metastatic sites, N of prior treatment lines, tumor sidedness, and presence of liver and peritoneal metastases. **Results:** Overall, 75 pts treated with FTD/TPI+Bev and 103 pts treated with Pan were included. In the unmatched populations, median PFS was 6.0 months with FTD/TPI+Bev vs 4.1 months with Pan (p<0.001). Median OS was 13.6 months and 11.6 months, respectively (p=0.756). ORR was 9.3% with FTD/TPI+Bev and 16.5% with Pan (p=0.172). After PSM, 68 pts per cohort were analyzed. Median PFS was 5.0 months with FTD/TPI+Bev vs 3.9 months with Pan [HR 1.65 (95% CI, 1.14-2.38), p=0.007]. Median OS was 13.1 months vs 11.6 months, respectively [HR: 0.89 (95% CI: 0.59-1.34); p=0.569]. ORR remained numerically higher in the Pan group, although not statistically significant (p=0.34). Results were consistent regardless of N of anti-EGFR-free lines [1 vs ≥2; HR for PFS: 0.85 (95% CI: 0.58-1.23), p=0.379; HR for OS 0.85 (95% CI: 0.56-1.29), p=0.446], type of prior anti-EGFR therapy [Pan vs Cetuximab; HR for PFS: 0.80 (95% CI: 0.58-1.10), p=0.163; HR for OS 0.87 (95% CI: 0.61-1.24), p=0.435], and response to previous anti-EGFR treatment [HR for PFS: 0.87 (95% CI: 0.59-1.28), p=0.485; HR for OS 0.80 (95% CI: 0.59-1.28), p=0.279]. Toxicity profiles differed between treatments: neutropenia (any grade (G) 52% vs 3%; G3-4: 37% vs 1%), anemia (39% vs 15%; G3-4: 5% vs 1%), nausea (25% vs 10%; G3-4: 4% vs 0%), thrombocytopenia (24% vs 7%; G3-4: 4% vs 0%) and hypertension (21% vs 1%; 4% vs 0%) were more frequent with FTD/TPI+Bev, whereas rash occurred exclusively in the Pan group (81%; G3-4: 19%). **Conclusions:** Although underpowered, this indirect comparison suggests that FTD/TPI+Bev may achieve longer PFS than Pan re-treatment in pretreated mCRC pts, while anti-EGFR rechallenge may be associated with numerically higher response rate, with no OS difference. Prospective randomized trials are warranted to confirm these findings. Research Sponsor: None.

A multi-omic analysis of EOCRC: Divergent methylation and gene expression signatures in young patients. First Author: Ning Jin, The Ohio State University, Columbus, OH

Background: The incidence of early-onset colorectal cancer (EOCRC; diagnosis $<$ 50 years) is rising at an alarming rate. EOCRC often exhibits distinct clinical features compared to late-onset colorectal cancer (LOCRC), yet the underlying mechanisms remain poorly understood. This study aimed to characterize a cohort of EOCRC patients by integrating DNA methylation, gene expression, and metabolomic profiles to identify age-specific molecular drivers. **Methods:** We performed an integrated multi-omic analysis on a cohort of 42 patients, comprising 16 EOCRC and 26 LOCRC cases that were collected from the Total Cancer Care at the Ohio State University. For each patient, fresh-frozen tumor tissue and paired adjacent normal tissue were analyzed using reduced representation bisulfite sequencing (RRBS). Parallel transcriptomic profiling was conducted by RNA-seq on all tumor samples. Additionally, systemic metabolic signatures were captured from plasma using liquid chromatography-mass spectrometry (LC-MS). Functional integration of differentially methylated regions (DMRs), gene expression signatures, and metabolomic profiles was performed using Ingenuity Pathway Analysis (IPA) to identify enriched canonical pathways. **Results:** Integrative analysis revealed a divergent molecular fingerprint in EOCRC compared to LOCRC. At the epigenomic and transcriptomic levels, EOCRC tumors demonstrated significant enrichment in neurotransmitter-related pathways, such as CREB signaling in neurons and ion channel transport, alongside a pronounced activation of G-protein coupled receptor (GPCR) signaling. Furthermore, we identified a distinct immune-related signature characterized by the activation of phagosome formation and S100 family signaling pathways. These intracellular alterations were mirrored by a unique systemic metabolic profile involving the G alpha signaling pathway and the transport of vitamins, nucleosides, bile salts, and amine compounds. In addition, we identified a multi-omic signature of 11 genes that exhibit both differential gene expression between EOCRC and LOCRC tumors and significant tumor-specific methylation drift relative to adjacent normal tissue. Notably, this signature is enriched with established epigenetic clock/aging markers, including *LEP*, *PLA2G4F*, *CYP2E1*, *GCM2*, *ZNF418*, and *MINAR1*, making them ideal candidates for early detection by liquid biopsies or risk-stratification tools for EOCRC. **Conclusions:** Our findings demonstrate that EOCRC is a biologically distinct entity driven by specific epigenetic and immune dysregulation. The simultaneous enrichment of neurotransmitter pathways and GPCR signaling suggests that EOCRC development may be uniquely influenced by neuro-epithelial interactions. The 11-gene signature enriched with epigenetic aging markers may serve as screening or surveillance tools for EOCRC patients. Long-term responders to trifluridine/tipiracil plus bevacizumab in previously treated metastatic colorectal cancer: Results from the BeTAS real-world study. First Author: Nieves Martinez Lago, Department of Medical Oncology. Hospital Clínico Universitario e Instituto de Investigación Sanitaria de Santiago de Compostela, Santiago de Compostela, Spain

Background: The phase III SUNLIGHT trial established trifluridine/tipiracil plus bevacizumab (FTD/TPI+BEV) as a standard treatment option for metastatic colorectal cancer (mCRC) after failure of at least two prior regimens. However, limited evidence exists regarding patients achieving durable benefit in routine clinical practice. We aimed to characterize the prevalence, clinical features, and outcomes of long-term responders treated with FTD/TPI plus bevacizumab in a large real-world cohort. **Methods:** BeTAS is a multicenter ambispective real-world study conducted within the Galician Research Group on Gastrointestinal Tumors. Consecutive patients with previously treated mCRC receiving FTD/TPI+BEV after failure or intolerance to $\geq$2 prior regimens were included. Long-term responders (LTRs) were defined using a pre-specified landmark of progression-free survival (PFS) $\geq$9 months. Baseline characteristics, treatment response, and survival outcomes were compared between LTRs and non-LTRs. Overall survival (OS) was assessed using a 9-month landmark analysis to minimize immortal time bias. Survival was estimated using the Kaplan–Meier method and compared using the log-rank test. Multivariable Cox regression was performed. **Results:** Among 576 patients, median PFS and OS were 4.9 months (95% CI 4.3–5.5) and 10.8 months (95% CI 9.8–11.9), respectively. LTRs accounted for 20.3% of the cohort (n=117). Compared with non-LTRs, LTRs more frequently had $\leq$2 metastatic sites (83.8% vs 67.5%, p=0.001), absence of liver metastases (28.4% vs 16.7%, p=0.004), longer time from metastatic diagnosis (p=0.046), and Tabernero best prognostic characteristics (p=0.007). Among evaluable patients, objective response rate was higher in LTRs (22.1% vs 5.5%, $p<0.001$), as was disease control rate (100% vs 39.0%, $p<0.001$). Median PFS was 15.3 versus 3.6 months, and landmark OS was 23.5 versus 8.1 months (both $p<0.001$). Long-term response remained independently associated with improved OS (HR 0.19, 95% CI 0.14–0.26; $p<0.001$). **Conclusions:** In real-world practice, approximately one in five previously treated patients with mCRC achieve durable benefit with FTD/TPI+BEV. Identification of clinical factors associated with long-term response may support improved patient selection in later-line treatment. Research Sponsor: None.

Correlative analysis of ctDNA in CheckMate-9X8 study of frontline treatment with mFOLFOX6, bevacizumab with or without nivolumab in metastatic colorectal cancer. First Author: Jin Yao, Bristol Myers Squibb, Princeton, NJ

Background: The CheckMate 9X8 study evaluated ctDNA as biomarker to predict treatment benefit in metastatic colorectal cancer (mCRC) patients receiving standard-of-care therapy with or without nivolumab. Although the phase 2/3 trial did not meet its primary PFS endpoint, the addition of nivolumab appeared to confer clinical benefit in a subset of patients. As predictive biomarkers for first-line nivolumab in mCRC remain unvalidated, this exploratory analysis identified mutation- and methylation-based ctDNA signatures that may help inform future patient stratification and disease management. **Methods:** Study design and methods were published previously (Lenz, et al. JITC 2024). As part of an exploratory biomarker analysis, paired plasma samples (baseline and on-treatment at C3D1) were evaluated for circulating tumor DNA (ctDNA) using PredicineATLAS (600-gene) comprehensive genomic profiling, PredicineSCORE (Low-pass whole-genome sequencing), and PredicineEPIC (methylation) assays and correlated with baseline patient characteristics and treatment efficacy. **Results:** Over 98% (138/140) of baseline patients had quantifiable ctDNA with Predicine ATLAS and approximately 83% (116/140) had detectable copy number variants (CNV) with PredicineSCORE. High concordance was observed between ctDNA-derived mutations and tissue-derived KRAS, TP53, and APC mutations and MSI/MSS status at baseline. 97% of patients with KRAS G12D/V/C mutations positively identified by local tissue testing were also positively identified by ctDNA. 6% of subjects considered KRAS wild-type by local tissue testing were identified as having KRAS G12D/V/C mutations by ctDNA. KRAS mutations, wild-type TP53, chromosomal loss of 18q21.33, high methylation scores and hypomethylated Tetraspanin 15 correlated with treatment efficacy. Neo-KRAS WT, or loss of KRAS mutations on treatment, emerged during treatment in 36% of patients with KRAS mutations at baseline and was associated with improved survival. Significant ctDNA level reduction was seen during treatment in both arms of the study irrespective of tumor response. These insights underscore the promise of ctDNA profiling in enhancing precision medicine by enabling real-time, dynamic assessment of tumor biology and therapeutic response with a potential to guide personalized treatment strategies for mCRC patients in the future. **Conclusions:** This study highlights the potential utility of liquid biopsy in the mCRC setting and provides novel insights from the ctDNA analysis, highlighting genetic and epigenetic ctDNA features that might be associated with clinical efficacy of SOC $\pm$ nivolumab in 1L mCRC. The emergence of Neo-KRAS WT in a substantial number of patients indicates a dynamic nature of KRAS alterations and highlights the additional value that longitudinal plasma ctDNA analysis could provide. Clinical trial information: NCT03414983. Research Sponsor: None.

Circulating tumor DNA for characterizing intratumor heterogeneity and outcomes in metastatic colorectal cancer. First Author: Cynthia Yeung, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Intratumor heterogeneity (ITH) drives CRC resistance, yet tissue-based assessments remain limited. ctDNA captures heterogeneity, though variable tumor fractions confound measurements. We assessed raw vs fraction-adjusted ITH in ctDNA for overall survival (OS) in metastatic CRC (mCRC). **Methods:** We analyzed two real-world mCRC cohorts from MD Anderson: a 73-gene panel (1,137 patients, 2014-2023; limit of detection (LoD) 0.1%) and a 701-gene panel (150 patients, 2024-2025; LoD 0.5%). Quality filters included $\geq$ 3 detected variants, MaxVAF $>$ 0.01, and bioinformatic filtering of putative germline variants. ITH was quantified via raw Mutant-Allele Tumor Heterogeneity (rMATH; VAF distribution width) and the Shannon entropy-based, MaxVAF-normalized (VAF/Max_VAF) blood ITH (bITH; multiplies bin entropy by clonality weights). OS was assessed using Cox models by continuous variables and optimal cut-points determined by maximally selected log-rank statistics. A stress test subset (top 50% MaxVAF) was analyzed to decouple findings from analytical noise inherent at low tumor fractions. **Results:** In the 73-gene cohort (median age 53.2; 91% MSS, 14% BRAF mutated, 64% RAS mutated), MaxVAF was the strongest predictor of worse OS in both univariable (HR 1.32, p $<$ 0.001) and multivariable (MV) models (HR 1.31, p $<$ 0.001). Paradoxically, high rMATH was associated with improved OS (MV HR 0.89, p = 0.014). This protective signal of high heterogeneity was more pronounced in the dichotomized model (MV HR 0.71, p $<$ 0.001) and persisted in the subset of high-burden patients (top 50% MaxVAF) (MV HR 0.69, p $<$ 0.001) and the MSS subset (MV HR 0.68, p = 0.003). In the 701-gene panel cohort, MaxVAF remained the dominant independent predictor (MV HR 2.37, p $<$ 0.001). bITH was not independently prognostic (MV HR 0.98, NS). **Conclusions:** MaxVAF serves as the primary ctDNA-derived driver of clinical outcomes in mCRC, confirming that ctDNA-inferred ITH metrics are heavily confounded by total tumor shedding. The unexpected association between high rMATH and improved OS suggests that increased clonal diversity, at a fixed tumor burden, may indicate a less evolutionarily pruned or consolidated tumor compared to those that have undergone a selective clonal sweep. These results highlight that while ctDNA can characterize clonal architecture, the clinical interpretation of heterogeneity must be contextualized within the tumor's total systemic volume and evolutionary state. Research Sponsor: Conquer Cancer, the ASCO Foundation.

Cohort	Variable (High vs Low)	Multivariable HR (95% CI)*	p-value

Influence of neoadjuvant therapy on tumor-vascular-immune stromal networks in colorectal cancer liver metastases. First Author: Pia J. Osterlund, Tampere University Hospital, Tampere, Finland

Background: Neoadjuvant therapy's effect on vascular, tumor, and immune compartments, and their co-regulation, in colorectal liver metastases (CRLMs) remains poorly understood. We performed multiplex-based tissue profiling to quantify how treatment reshapes stromal compartment and co-occurrence networks, defined by inside-case correlations between features. **Methods:** We analyzed 76 CRLM cases (27 untreated, 49 neoadjuvant-treated [43 chemotherapy, 6 chemo + VEGF-/EGFR-targeted]). Tissue microarrays (1-3 1-mm cores/tumor) underwent multiplex immunofluorescence to quantify immune/tumor subsets (CD3/CD4/CD8/PD-1/FOXP3/TIM-3/Ki67/CDX2), vessels (claudin-5), and stromal perivascular compartments (αSMA/PDGFRβ). Statistical analysis included Mann-Whitney U tests and Spearman correlations. **Results:** Neoadjuvant-treated CRLMs had 42% fewer proliferating tumor cells ($CDX2^+KI67^+$density, p=0.006) and 33% lower $CDX2^+$ density (p=0.031) compared with untreated CRLMs. This was accompanied by a 32% reduction in proliferating cytotoxic T-cells ($CD3^+CD8^+Ki67^+$ density, p=0.029). A reduction in vessel size was also observed in treated CRLMs (vessel size, -12%, p=0.077). Analyses suggested different effects by type of neoadjuvant treatment. Chemotherapy alone reduced proliferating tumor cells ($CDX2^+KI67^+$ density, -37%, p=0.016) and suppressed cytotoxic T-cell proliferation ($CD3^+CD8^+Ki67^+$ density, -40%, p=0.017). The addition of VEGF/EGFR-targeted agents produced the most pronounced reduction in tumor burden ($CDX2^+$ density, -73%, p=0.012; $CDX2^+KI67^+$ density, -76%, p=0.010) vs. untreated. CRLM co-occurrence networks were also affected by treatment. Treatment abolished positive correlations between tumor cells ($CDX2^+$ and $CDX2^+KI67^+$ densities) and $\alpha SMA^+PDGFR\beta^+$ perivascular fraction/vessel size (r=+0.42 – +0.60, $p<0.05$), and negative correlations between tumor cells and $\alpha SMA^+PDGFR\beta^-$ perivascular fraction/vessel density (r=-0.47 – -0.40, $p<0.05$) in untreated (vs +0.05 – +0.27 and +0.09 – +0.21, p=n.s., in treated). Treatment also eliminated positive correlations between vessel size and exhausted ($CD8^+PD\text{-}1^+$) and regulatory ($CD4^+FOXP3^+$) T-cell densities (untreated r=+0.40 – +0.47, $p<0.05$). In parallel, new positive links emerged between $\alpha SMA^-PDGFR\beta^+$ perivascular fraction and $CD4^+$ and $CD8^+$ T cells (r=+0.41 – +0.42, $p<0.05$). **Conclusions:** This exploratory study indicates that neoadjuvant treatment alters the CRLM microenvironment, affecting tumor, vascular, and immune compartments. Additionally, analyses suggest that treatment induces a restructuring of their interdependence networks, defined by the loss of specific tumor-stromal-vascular links seen in untreated CRLMs, while establishing new ones. These findings motivate continued mechanistic studies and analyses on how these changes are related to benefits of treatment. Research Sponsor: None.

Clinical efficacy of laparoscopic hybrid surgery versus total open surgery for simultaneous resection of colorectal cancer liver metastases (CHLH trial). First Author: Wei Zhang, Department of Colorectal Surgery, Changhai Hospital, Naval Medical University, Shanghai, China

Background: Despite widespread adoption of simultaneous resection for colorectal liver metastases, the clinical efficacy varies among different approaches, and the optimal surgical strategy remains controversial. This study aims to evaluate the efficacy and safety of laparoscopic hybrid surgery (LHS) versus total open surgery (TOS) in the simultaneous resection of CRLM. **Methods:** This is a prospective cohort study (NCT06550700) conducted at a tertiary medical center, enrolling 266 patients who underwent simultaneous resection for CRLM from January 2017 to June 2021. The surgical approach is selected by colorectal surgeons and hepatobiliary surgeons based on their experience with either TOS or LHS. The primary outcomes were the incidence of complications and postoperative recovery-related outcomes. The secondary outcomes were 5-year overall survival (OS) and disease-free survival (DFS). **Results:** This study ultimately enrolled 144 patients in the LHS group and 122 patients in the TOS group. The complication rate was significantly lower in the LHS group than in the TOS group (10.4% vs. 20.5%, p = 0.022). Compared with the TOS group, patients in the LHS group had shorter postoperative hospital stay [8.00 (6.00, 10.00) vs. 9.00 (8.00, 12.00) days, $p < 0.001$], earlier resumption of liquid intake [3.00 (3.00, 3.00) vs. 4.00 (3.00, 4.00) days, $p < 0.001$], and less intraoperative blood loss [300.00 (200.00, 400.00) vs. 500.00 (500.00, 700.00) mL, $p < 0.001$]. However, the LHS group was associated with longer operative time [260.00 (236.00, 320.00) vs. 240.00 (195.00, 269.00) min, $p < 0.001$]. No significant differences were observed between the two groups in overall survival (p = 0.464) or disease-free survival (p = 0.838). **Conclusions:** Compared with TOS, applying LHS for simultaneous resection for CRLM results in faster postoperative recovery, lower complication rates, and similar survival outcomes. A four-marker-protein signature to predict ramucirumab efficacy in combination with TAS-102 in advanced colorectal cancer: Translational analysis of the RAMTAS trial of the German AIO (AIO-KRK-0316/IKF643). First Author: Thomas Seufferlein, Department of Internal Medicine I, Ulm University Hospital, Ulm, Germany

Background: The combination of TAS-102 and bevacizumab is standard in the treatment of advanced colorectal cancer (aCRC). Ramucirumab (Ram) is a mAb that blocks VEGFR2. Ram in combination with Tas-102 did not improve OS compared to Tas-102 alone in the ITT population of the RAMTAS trial. Subgroups such as female patients (pts) and pts with left-sided tumors appeared to benefit from the combination (DOI:10.1016/j.annonc.2024.08.2264). Here we aimed at identifying angiogenesis-related, soluble, predictive biomarkers defining a RAMTAS subpopulation benefitting from the addition of Ram to Tas-102. **Methods:** Serum samples were available from 194 of 428 pts from the RAMTAS study (96 pts randomized to TAS-102, 98 pts to TAS-102 plus Ram). Serum levels of 85 angiogenesis-related proteins obtained prior to treatment with Tas-102 +/- Ram (baseline, BL) and at cycle 2 day 1 prior to the start of the next cycle (treatment, TR) were quantified via multiplex-ELISA by Myriad-RBM. Multivariate Cox regression models were developed within the combination arm using stepwise selection and ridge regularization. Model performance was assessed via C-index and validated using 10 x 5-fold cross-validation (CV) as well as full quality control for multicollinearity and proportional hazard assumptions. To distinguish predictive from general prognostic effects, the identified signatures were applied to the monotherapy control arm. **Results:** A TR model incorporating just 4 serum proteins demonstrated robust discrimination in the combination arm (Training C-index: 0.712; CV C-index: 0.708 ± 0.063). This model successfully stratified patients into a "Ram benefit" and a "no Ram benefit" group with a corresponding median PFS of 7.0 mo and 1.9 mo, respectively (HR 6.97, $p < 0.001$). A Baseline (BL) model yielded a C-index of 0.699, also utilizing just 4 serum proteins. Application of both models to the TAS-102 mono arm resulted in poor discrimination (C-index ~0.60) indicating that the signatures are specific predictors for the combination. In a comparative survival analysis, "Ram-benefit" TR model patients achieved a significantly longer PFS with the combination compared to monotherapy (7.00 vs. 2.14 mo; HR 0.558, p=0.0078). Conversely, "no-Ram-benefit" patients derived no significant benefit from the addition of Ram (PFS 1.91 vs. 1.91 mo; HR 0.946, p=0.4204). **Conclusions:** Oligo-marker serum signatures, when incorporating early on-treatment dynamics after one cycle of Tas-102/Ram, may effectively predict a survival benefit for aCRC-pts receiving TAS-102 in combination with Ram. We propose that a two-stage "Screen & Monitor" (BL+TR) strategy will help to identify primary refractory patients who gain no benefit from the addition of Ram. Such an approach could maximize therapeutic utility while reducing potential toxicity. Clinical trial information: NCT03520946. Research Sponsor: Lilly.

Real-world outcomes and recurrence risk factors of liver transplantation for permanently unresectable colorectal liver metastases following the TransMet trial. First Author: Rene Adam, Paul Brousse Hospital - APHP, Villejuif, France

Background: Following the TRANSMET trial that demonstrated an overall survival (OS) benefit of liver transplantation (LT) over chemotherapy (CT) alone for selected patients with permanently unresectable colorectal liver metastases (uCRLM), the program of LT has continued in France with the same eligibility criteria, independent validation and graft allocation policy. We assessed the real-world oncological outcomes and prognostic factors for post-LT recurrence-free survival (RFS) in the whole cohort. **Methods:** This nation-wide analysis pooled both patients transplanted in TransMet (Trial cohort) and those after trial closure (Extension cohort). OS and RFS were evaluated in each cohort. Multivariable Cox models for RFS using sensitivity analyses including forced cohort adjustment and bootstrap resampling were performed. **Results:** A total of 87 patients underwent LT (37 Trial cohort; 50 Extension cohort). Baseline characteristics at CRLM diagnosis were comparable. At LT, patients in the Extension cohort received significantly fewer CT cycles ($\geq$24 cycles, 16% vs 41%, p=0.01) and showed higher rate of partial response (94% vs 57%, $p < 0.001$) after first-line CT. At time of LT, tumor burden, RECIST status and tumor markers were similar. Median follow-up was shorter in the Extension cohort (16 vs 57 months). No significant differences in OS and RFS were observed between extension and trial cohorts (30-months OS 89% vs 81%; 30-months RFS 47% vs 39%, respectively). In univariable analysis, risk factors of RFS included $\geq$2 CT lines, $\geq$24 CT cycles before LT, CEA at LT $>$ 5 ng/mL, progression on CT and interval from primary tumor surgery $>$2 years. In multivariable Cox analysis, $\geq$2 lines or $>$24 cycles before LT (HR 2.90, 95% CI 1.32–6.36; $p<0.01$) and CEA at LT $>$5 ng/mL (HR 2.26, 95% CI 1.18–4.33; p=0.01) remained independently associated with RFS, adjusted on interval from primary tumor surgery. Bootstrap resampling (2,000 iterations) highlighted these results in 82% and 67% of models, respectively. **Conclusions:** LT for uCRLM gives good and reproducible oncological outcomes across trial and extension cohorts. This exploratory analysis supports that RFS is impaired by a prolonged pre-transplant chemotherapy ($\geq$ 2 lines or $\geq$ 24 cycles) and improved by a good biological response (normalization of CEA), supporting considering LT in a multidisciplinary setting as soon as definitive unresectability is established. Dynamic circulating tumor DNA profiling for prediction of long-term clinical benefit in pMMR locally advanced rectal cancer receiving neoadjuvant chemoradiotherapy plus sintilimab. First Author: Xiaobin Zheng, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China

Background: Immune checkpoint inhibitors (ICIs) targeting PD-1 have significantly improved outcomes in locally advanced rectal cancer (LARC). Circulating tumor DNA (ctDNA) has emerged as a promising biomarker for treatment response monitoring and surveillance, capable of predicting long-term clinical outcomes. However, whether ctDNA serves as a prognostic predictor in patients with proficient mismatch repair (pMMR) LARC receiving neoadjuvant chemoradiotherapy (CRT) combined with immunotherapy remains to be explored. **Methods:** This prospective single-arm phase II trial enrolled pMMR LARC patients ($cT_{3\text{-}4}N_0M_0$ and $cT_{1\text{-}4}N_{1\text{-}2}M_0$) with an intermediate or high immunoscore (IS_B) (NCT05450029). Treatment-naïve patients received radiotherapy (50 Gy/ 25 fractions), 6 cycles of mFOLFOX6, and 5 cycles of sintilimab, followed by total mesorectal excision (TME) 6-8 weeks post-radiotherapy. Next-generation sequencing was used to evaluate baseline tumor tissue DNA and serial ctDNA dynamic changes. Baseline (T0) maximal somatic variant allelic frequency (maxVAF) was assessed, along with its changes at the first (T1, two cycles after therapy) and second clinical evaluation (T2, four cycles after therapy). **Results:** Tumor somatic mutations and aligned ctDNA analyses were conducted in 43 patients. The pathologic complete response (pCR) rate was 65.2%, with an objective response rate (ORR) of 93.5%. The R0 resection rate was 97.8%. The 3-year event-free survival rate, and 3-year overall survival rate remain immature. For dynamic ctDNA analysis, 37 patients were assessed using a 950-gene panel relevant to cancer. A significant decline in maxVAF from T0 to T1 was observed in the pCR group. Among patients who reached follow-up endpoints, circulating tumor DNA analysis reveals that patients with a $>$ 50% decline in maxVAF from T0 to T1 demonstrated longer survival outcomes and higher response rates compared to those without such decline. **Conclusions:** Serial ctDNA analysis demonstrates applicability in predicting treatment response to CRT combined with immunotherapy in pMMR LARC. Dynamic changes in circulating ctDNA may serve as a potential prognostic indicator in this population. Future studies should integrate ctDNA profiling of comprehensive cancer-related gene panels with large-scale clinical data to refine patient stratification and optimize therapeutic management. Safety and efficacy of ifebemtinib combined with garsorasib in KRAS G12C mutant colorectal cancer from a randomized part of a phase Ib/II study. First Author: Xiangdong Cheng, Zhejiang Cancer Hospital, Hangzhou, Zhejiang Province, China

Background: Studies (Yaeger R, et al.; Fakih, MG, et al.) have shown when RASi is combined with optimal therapeutic partner(s), clinical efficacy and benefit can be maximized. Ifebemtinib (ifebe) is a highly potent and selective oral inhibitor of focal adhesion kinase (FAK) that exhibits synergistic effect with RASi in both preclinical and clinical setting. Garsorasib (D-1553) is a novel KRAS G12Ci approved in China for treatment of KRAS G12C mutant NSCLC. We previously reported a promising objective response rate (ORR) of 44.4% in patients (pts) with KRAS G12C mutant CRC receiving ifebe + D-1553, with the durability of efficacy yet to be confirmed. Herein, we present the updated results with median follow-up of (14.4 months) from a randomized cohort of phase Ib/II study, comparing ifebe + D-1553 vs D-1553 alone in KRAS G12C mutant CRC, to elucidate the relative therapeutic contribution of ifebe and durability of response. **Methods:** Metastatic KRAS G12C mutant CRC pts with at least 1 prior line of systemic anticancer therapy were enrolled in a randomized part and randomized 1:1 to ifebe (100mg QD) + D-1553 (600mg BID) or D-1553 (600mg BID) alone. **Results:** As of January 4, 2026, 36 previously treated metastatic CRC pts were enrolled, with 18 pts in ifebe + D-1553 group and 18 pts in D-1553 group ($\geq$3 prior lines of treatment: 33.3% vs 27.8%; liver metastasis: 55.6% vs 72.2%). The median treatment duration was 8.5 months vs 3.6 months and 4 pts (3 [16.7%] vs 1 [5.6%]) were still on treatment. The hazard ratio (HR) for progression free survival (PFS) and overall survival (OS) was 0.47 and 0.44, respectively, demonstrating the durability of efficacy in pts receiving ifebe + D-1553 (Table). The safety profiles of ifebe + D-1553 in CRC pts are comparable to each single agent. No ifebe or D-1553 related death or AEs leading to drug withdrawal were reported. **Conclusions:** The combination of ifebe and D-1553, a dual-oral regimen, exhibits favorable safety profiles and better efficacy in treating KRAS G12C mutant CRC, with mOS exceeding 16 months. Clinical findings from this randomized study have shown robustness of improvement in overall ORR, PFS, DOR and OS benefit with this combination regimen, indicating that adding ifebe to a RASi can further improve clinical outcome to CRC patients with RAS G12C mutation. Clinical trial information: NCT06166836. Research Sponsor: None.

Reduced oxaliplatin exposure in gastrointestinal cancers: A systematic review and meta-analysis. First Author: Wallace Klein Schwengber, Division of Hematology and Oncology, Mayo Clinic Arizona, Phoenix, AZ

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a frequent dose-limiting toxicity from oxaliplatin that impairs quality of life in gastrointestinal (GI) cancer patients (pts). While strategies to limit exposure exist, their impact on survival remains debated. We evaluated whether reduced oxaliplatin exposure (ROE) maintains survival while mitigating toxicity. **Methods:** We conducted a systematic review and meta-analysis (PubMed, Embase, Scopus, Web of Science, EBM Reviews) of studies comparing ROE vs standard-duration oxaliplatin-based chemotherapy in GI cancers. ROE was defined as planned limitation of oxaliplatin exposure, including shortened duration (3-4 months), maintenance-based de-escalation, or stop-and-go strategies. Primary endpoints were disease-free survival (DFS) in curative settings, progression-free survival (PFS) in palliative settings, and overall survival (OS). Secondary endpoints included grade $\geq$3 CIPN and grade $\geq$3 adverse events (AEs). Random-effects models used Hartung-Knapp-Sidik-Jonkman correction. Heterogeneity was assessed via I^2 and Cochran's Q. **Results:** 24 studies, comprising 15 randomized controlled trials (RCTs) and 9 retrospective cohorts, were included (N = 30,404 pts; ROE: 13,348; control: 17,056). Settings included adjuvant colorectal cancer (CRC; n = 14), metastatic CRC (mCRC; n = 5), gastric cancer (GC) (adjuvant n = 1, metastatic n = 3), and metastatic pancreatic cancer (PDAC) (n = 1). ROE strategies included shortened duration (n = 14), maintenance (n = 8), and stop-and-go (n = 2). In adjuvant CRC, ROE did not compromise DFS (HR 1.07; 95% CI, 0.98-1.16; p = 0.12; I^2 = 21.7%), including in high-risk subgroups (HR 1.14; 95% CI, 0.93-1.40; p = 0.14; I^2 = 38.9%); OS was also not different between groups (HR 1.00; 95% CI, 0.94-1.07; p = 0.89; I^2 = 0%), including high-risk pts (HR 1.01; 95% CI, 0.93-1.10; p = 0.68; I^2 = 0%). In mCRC, ROE showed no detriment to PFS (HR 1.11; 95% CI, 0.99-1.25; p = 0.07; I^2 = 0%) or OS (HR 1.06; 95% CI, 0.92-1.23; p = 0.33; I^2 = 0%). Similarly, in metastatic gastric cancer, PFS (HR 0.82; 95% CI, 0.34-1.99; p = 0.44; I^2 = 77.3%) and OS (HR 0.90; 95% CI, 0.67-1.21; p = 0.26; I^2 = 0%) were comparable. Findings remained concordant after restricting the analysis to only RCTs. Pooled analysis was not feasible for PDAC and adjuvant GC studies, but individual study findings were consistent with the above. ROE significantly reduced the risk of grade $\geq$3 CIPN (OR 0.32; 95% CI, 0.20-0.53; p $<$ 0.001; I^2 = 80.6%) and overall grade $\geq$3 AEs (OR 0.65; 95% CI, 0.50-0.86; p = 0.01; I^2 = 59.9%). **Conclusions:** Across GI malignancies, ROE was not associated with inferior DFS, PFS, or OS and was associated with lower rates of severe neurotoxicity and high-grade AEs. These findings support planned limitation of oxaliplatin exposure as a strategy to improve the therapeutic index of oxaliplatin-based chemotherapy across disease settings. Research Sponsor: None.

3593 **Poster Session**

Data from a real-world study: Association of CDCP1 expression level with survival outcomes in mCRC patients treated with bevacizumab or cetuximab plus chemotherapy. First Author: Yitzhar Efraim Goretsky, Division of Medical Oncology, Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA

Background: CUB domain-containing protein 1 (CDCP1) is a transmembrane protein shown to be over-expressed in colorectal cancer (CRC), with an important role in tumor initiation, growth and metastasis. Through interactions with EGFR, CDCP1 promotes nuclear translocation of the key regulators of Wnt signaling, β-catenin and E-cadherin. High CDCP1 expression has been associated with poor survival outcomes in multiple solid tumors but data in CRC remains limited. We investigated associations between CDCP1 level and survival outcomes in patients with metastatic CRC (mCRC) in the phase III clinical trial CALGB/SWOG 80405 (Alliance). **Methods:** Data from 433 mCRC patients in the CALGB/SWOG 80405 (Alliance) trial were analyzed. Patients received bevacizumab (n = 226) or cetuximab (n = 207) plus chemotherapy as 1st-line treatment. Tumor RNA was extracted from FFPE samples and processed through the HiSeq 2500 (Illumina) platform. Overall survival (OS) and progression free survival (PFS) curves were evaluated in all treatment subgroups and stratified according to high or low CDCP1 expression. Likelihood ratio tests, hazard ratios (HRs), and 95% confidence intervals (CIs) were calculated using Cox proportional hazards multivariate models, adjusting for age, sex, ECOG performance status, tumor location, number of metastatic sites, *KRAS* status, consensus molecular subtypes, and treatment arm. **Results:** Overall, low CDCP1 expression was associated with better OS compared to high expression (HR = 1.38; 95% CI 1.07-1.77; 35.8 vs 25.0 months, p = 0.045). Subgroup analysis re-demonstrated this pattern in males (HR = 1.64; 95% CI 1.64-2.28; 35.9 vs 23.6 months, p = 0.01), patients with MSS tumors (HR = 1.56; 95% CI 1.17-2.08; 36.7 vs 25.1 months, p = 0.0094), and patients treated with cetuximab+FOLFOX (HR = 1.79; 95% CI 1.16-2.77; 40.8 vs 24.0 months, p = 0.03). The effect of CDCP1 expression on PFS was less pronounced. Relative to high expression, low expression was associated with better PFS in males (HR = 1.49; 95% CI 1.10-2.03; 13.1 vs 9.8 months, p = 0.027) and left-sided tumors (HR = 1.50; 95% CI 1.10-2.04; 14.4 vs 10.1 months, p = 0.034). **Conclusions:** Our findings represent real-world data of the predictive role of CDCP1 in patients with mCRC undergoing anti-EGFR or anti-VEGF treatment. Consistent with studies of other cancers, we show that low CDCP1 expression is predictive of better survival outcomes, with subgroup analysis revealing associations in males, MSS tumors, and left-sided tumors. Among treatment groups, low CDCP1 expression is predictive of better OS in cetuximab+FOLFOX-treated patients, a key finding given CDCP1's close mechanistic ties to EGFR. Further studies should explore whether these associations are seen in other treatment modalities and whether CDCP1 blockade could represent a viable strategy in patients with high expression. Research Sponsor: National Cancer Institute.

Multimodality neoadjuvant downstaging therapy before liver transplantation for colorectal liver metastasis: Real-world data from the Cleveland Clinic. First Author: Mazhar Khalil, Cleveland Clinic, Cleveland, OH

Background: Liver transplantation (LT) has a clear survival benefit in advanced, unresectable, liver-confined colorectal cancer liver metastasis (CRLM). However, pre-transplant management and optimal selection criteria remain understudied and previously reported data indicate recurrence-free survival $<$40% at 3- and 5-years post-LT. **Methods:** 23 patients entered the protocol; 22 patients underwent LT (12/2017-12/2025) utilizing the Cleveland Clinic protocol for down-staging prior to LT. The protocol involves intensive locoregional therapy (LRT) with systemic chemotherapy, aiming to reach minimal disease burden based on FDG PET-CT, ctDNA, and CEA. Patients with minimal or no detectable disease or irreversible treatment-induced liver injury undergo transplant. Patients must have disease control for at least 1 year after resection of the primary colorectal tumor. **Results:** Median age at LT was 45 years (IQR=39-50). Median largest tumor size on pre-LT imaging was 2.2 cm (1.6–7.35), and 18 patients (82%) had bilobar disease. Most patients received intensive systemic therapy (median=18 cycles, IQR=12-37), including 5-FU (n=18), oxaliplatin (n=18), irinotecan (n=13), and bevacizumab (n=17). Tumors were KRAS (n=6) and BRAF non-V600E (n=2) mutated. 20 patients (91%) received pre-LT LRT, including radioembolization (n=11), ablation (n=9), resection (n=10), and HAI pump (HAIP) (n=7). Only one patient dropped out of the pre-LT protocol for liver failure in 2017, suspected from combination of bilobar Y90 and SBRT. Pre-LT PET showed metabolic activity in 8 patients (36%). Median PET-Metabolic Tumor Volume (MTV) at protocol entry was 49.2cm^3 (18-162) and at LT was 0cm^3 (0-6.4) with a median MTV-reduction of 45.2cm^3 (18-156). Median MELD-Na at LT was 9 (IQR 6–13). Pre-LT tumor agnostic ctDNA was detected in 12/17 patients (71%). All patients with ctDNA(-) pre-LT had non-viable tumor on explant (n=5/5 vs. ctDNA(+)=5/12, p=0.028). At median follow-up of 1.6 years, 20 (91%) remain alive, and 18 (82%) are recurrence-free. Median RFS was 5.4 years (95%CI=3.52-7.36) and OS=6.72 years (95%CI=5.34-8.00). Recurrences were lung (n=2), liver (n=1), and liver+para-aortic (n=1) nodes. There was no post-LT recurrence when non-viable on PET scan and on histology (log-rank p$<$0.001). Pre-LT PET-MTV$>$70cm^3 correlated with histologically viable tumor (p=0.031). Pre-LT HAIP demonstrated a trend towards non-viable tumor on explant (n=5/7 non-viable, 71%). **Conclusions:** LT for CRLM shows clear survival benefit in randomized trials. Aggressive pre-LT locoregional and systemic therapies aimed at minimizing disease burden assessed by PET scan and ctDNA may demonstrate improved outcomes, as may HAIP. A clinical trial testing these hypotheses has been designed with expected enrollment in 2026 at three sites. Research Sponsor: None.

Tumor-informed versus tumor-agnostic ctDNA assays for molecular residual disease detection in colorectal cancer: A systematic review and meta-analysis. First Author: Nain Tara, Guthrie Robert Packer Hospital, Sayre, PA

Background: Circulating tumor DNA (ctDNA) is increasingly used for detection of molecular residual disease (MRD) following curative-intent treatment for colorectal cancer (CRC). Two principal assay strategies exist: tumor-informed (TI) assays requiring prior tumor sequencing, and tumor-agnostic (TA) assays using fixed plasma-based panels. The relative prognostic and diagnostic performance of these approaches remain uncertain. Despite growing clinical adoption, no systematic comparison of their relative performance exists to guide assay selection. **Methods:** We performed a systematic review and meta-analysis in accordance with PRISMA 2020 guidelines. PubMed, Embase, Cochrane Library, and Web of Science were searched from inception to January 2025 for original studies evaluating ctDNA-based MRD detection after curative-intent treatment for CRC. Primary outcomes were hazard ratios (HRs) for recurrence-free survival (RFS) and diagnostic accuracy metrics (sensitivity and specificity). Random-effects models (DerSimonian-Laird estimator) were used to pool effect estimates; heterogeneity was assessed using I^2 statistics. Subgroup analyses were conducted by assay type (tumor-informed vs tumor-agnostic) and sampling strategy (landmark vs serial). Quality assessment was performed using QUADAS-2 for diagnostic studies and Newcastle-Ottawa Scale for prognostic studies. **Results:** Twenty-three studies comprising 9,847 patients met inclusion criteria. Eighteen studies evaluated tumor-informed assays (n=7,892) and eight evaluated tumor-agnostic assays (n=2,156), with three directly comparing both approaches. For tumor-informed assays, the pooled HR for recurrence in ctDNA-positive versus ctDNA-negative patients was 7.58 (95% CI, 6.21–9.25; I^2=24%). For tumor-agnostic assays, the pooled HR was 4.12 (95% CI, 3.18–5.34; I^2=18%). Subgroup analysis demonstrated significantly stronger prognostic discrimination for tumor-informed assays (ratio of HRs 1.84; 95% CI, 1.38–2.45; p$<$0.001). In serial sampling settings, tumor-informed assays achieved higher sensitivity for MRD detection than tumor-agnostic assays (88% vs 62%; p=0.002). At landmark timepoints, specificity was similar between approaches (97% vs 94%; p=0.08). Between study heterogeneity was low to moderate across analyses. **Conclusions:** Tumor-informed ctDNA assays demonstrate superior prognostic performance and higher sensitivity with serial sampling compared with tumor-agnostic approaches for MRD detection in colorectal cancer. TI assays may be preferred when longitudinal monitoring is feasible, while TA assays remain useful when tumor tissue is unavailable, or rapid results are needed. These findings support selection of ctDNA assay strategies based on clinical context. Research Sponsor: None.

The efficacy and safety of sosimerasib monotherapy in pretreated colorectal cancer with KRAS G12C mutation: Results from a phase 1b study. First Author: Lihui Liu, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China

Background: KRAS G12C mutation is a key driver in approximately 3-4% of colorectal cancer (CRC) cases with poor prognosis. Sosimerasib is a novel, potent, and highly selective KRAS G12C inhibitor. This Phase 1b study evaluates the efficacy and safety of sosimerasib in patients with KRAS G12C-mutated locally advanced or metastatic CRC. **Methods:** Eligible patients who had received prior standard chemotherapy were enrolled in this study. Patients were administered sosimerasib at 500 mg orally once daily. The primary efficacy endpoint was the objective response rate (ORR) assessed by investigators according to RECIST 1.1. **Results:** As of May 3, 2025, a total of 56 patients were enrolled with a median age of 59 years (53.6% male). All patients had stage IV disease at baseline with an ECOG score of 0 (19.6%) or 1 (80.4%). Prior treatment lines ranged from 1 to 3, and most patients (38; 67.9%) had received oxaliplatin, irinotecan, and fluoropyrimidine as systemic therapy during the advanced disease period. With a median follow-up period of 9.9 months (range: 2.1-13.4), the confirmed ORR was 39.3% (95% CI: 26.5-53.3), the median time to response was 1.4 months (range: 1.3-4.2), and the disease control rate was 98.2% (95% CI: 90.5-100). The median duration of response was 8.6 months (95% CI: 4.2-NA). The median progression-free survival was 8.3 months (95% CI: 5.6-11.0). The median overall survival (OS) was not reached, with a 12-month OS rate of 71.5%. Among the patients who had previously received oxaliplatin, irinotecan, and fluoropyrimidine in the advanced setting, the confirmed ORR was 31.6% (95% CI: 17.5-48.7). Treatment-related adverse events (TRAEs) were reported in 53 (94.6%) patients, with grade 3-4 TRAEs occurring in 14 (25.0%) patients. No TRAE was fatal. The most common TRAEs were increased alanine aminotransferase (48.2%), increased aspartate aminotransferase (46.4%), anaemia (32.1%), and decreased white blood cell count (26.8%). TRAEs led to drug interruption in 9 (16.1%) patients, dose reduction in 3 (5.4%) patients, and permanent discontinuation in 1 (1.8%) patient. **Conclusions:** Sosimerasib monotherapy demonstrated clinically meaningful anti-tumor activity with an acceptable safety profile in patients with KRAS G12C-mutated locally advanced/metastatic CRC, supporting its potential for further development. Clinical trial information: ChiCTR2200059986. Research Sponsor: None.

TAMS in appendiceal cancer: Association with metabolic remodeling, prognosis, and response to intra-tumoral therapy. First Author: Patrick Wagner, Allegheny Health Network Cancer Institute, Allegheny Health Network, Pittsburgh, PA

Background: Appendiceal cancer (AC) is a rare malignancy with a distinct immunobiology and propensity for peritoneal metastasis. Tumor-associated macrophages (TAMs) are recognized as influential immune cells in various cancers. In this study, we sought to define the role of TAMs in AC, given its unique immune landscape and peritoneal microenvironment. **Methods:** Immunohistochemistry-quantified M1-like (CD68+CD86+) and M2-like (CD68+CD206+) TAM densities in 112 archival AC specimens were compared against clinicopathologic features and overall survival (OS). In parallel, a comprehensive tissue proteomic analysis (LC-MS/MS) was performed. Gene set enrichment analysis identified proteomic signatures associated with M1 and M2 density. Independently prognostic proteins were identified via Cox regression. External validation was performed by correlating these proteomic signatures in independent tumor samples from the RIOT-1 clinical trial (NCT05751837), in which AC patients received intra-tumoral lipopolysaccharide (LPS), a TLR4 agonist. **Results:** M2-like TAMs outnumbered M1-like TAMs in AC (p = 0.0002), particularly in peritoneal metastases (p = 0.002), and were not associated with tumor grade or histology. Low M1 density ($<$ 18th percentile) correlated with worse OS (HR: 3.26, p = 0.03), while high M2 density ($>$ 52nd percentile) was associated with improved OS (HR: 0.1, p = 0.03). A combined high-M1/M2 percentile metric was highly prognostic of favorable OS (p $<$ 0.001), independent of age, grade, and disease extent. On proteomic analysis, M1-rich tumors exhibited high bioenergetic demands, extensive metabolic reprogramming (isoprenoid/amino acid metabolism), retinol/xenobiotic metabolism, while M2-rich tumors emphasized ECM remodeling, profound amino acid metabolism (immunosuppressive), oxidoreductase activity, and complement activation, with suppressed cell motility. The combined high-M1/M2 phenotype correlated with intense amino acid/lipid metabolism and redox homeostasis. Five TAM-related, independently prognostic proteins were identified: GATD1 (favorable, HR 1.53x10-16), and AGR2, ENOPH1, RHOA, SERPINB6 (adverse, HRs 5.51-10.39). In RIOT-1, intra-tumoral LPS increased M1/M2 TAM infiltration and induced proteomic changes significantly correlated with M1-related (p = 0.0016), M2-related (p = 0.008), and combined TAM signatures (p = 0.047), supporting therapeutic tractability. **Conclusions:** AC harbors a TAM-rich immune microenvironment in which M2-like TAMs and a combined M1/M2 phenotype paradoxically associate with favorable prognosis. Distinct TAM-linked metabolic programs and validated prognostic proteins suggest clinically relevant biologic underpinnings of these findings, while modulation of the AC microenvironment via regional innate immune activation may represent a promising therapeutic strategy. Research Sponsor: ACPMP.

3598 Poster Session

A multicenter randomized phase II trial assessing the efficacy and safety of mCapOX plus cetuximab with mFOLFOX6 plus cetuximab as first-line treatment for *RAS/BRAF* wild-type metastatic colorectal cancer: Updated results from the CAPCET study. First Author: Qiu Meng, West China Hospital, Sichuan University, Chengdu, Sichuan, China

Background: The CAPCET study was designed to assess the efficacy and safety of modified capecitabine and oxaliplatin (mCapOX) plus cetuximab (CET) and modified fluorouracil, leucovorin, and oxaliplatin (mFOLFOX6) plus cetuximab (CET) for the first-line treatment of left-side unresectable RAS/BRAF wild-type (wt) metastatic colorectal cancer (mCRC). **Methods:** CAPCET was an open-label, randomized, multicenter, phase II non-comparative trial (NCT05022030). Patients with unresectable RAS/BRAF wt mCRC from 20 China centers were randomly assigned (1:1) to receive up to 12 cycles biweekly mCapOX (capecitabine 1000mg/m^2 twice daily on Day 1-7 and oxaliplatin 85 mg/m^2 on Day 1) plus CET (500mg/m^2) (arm A) or mFOLFOX6 (oxaliplatin 85 mg/m^2, leucovorin 200 mg/m^2, fluorouracil 400mg/m^2 on day 1, and fluorouracil 2400 mg/m^2 over 46h) plus CET (500mg/m^2) (arm B) followed by maintenance (either capecitabine plus CET or capecitabine alone at the discretion of the investigators) or treatment-free intervals until progression on treatment, toxicity, or death. The primary endpoint was progression-free survival (PFS) rate at 9 months. This is an updated result with a median follow-up of 26.1 months and cost-effectiveness evaluation. **Results:** Between September 2021 and April 2024, 168 patients were enrolled in the intention-to-treat (ITT) population and 156 patients were included in the per-protocol (PP) population. In the ITT population, the 9 months-PFS rates were 67.9% (95% CI 58.6%-78.6%) in arm A and 61.9% (95% CI 52.3%-73.2%) in arm B, and the primary endpoint was met. The median PFS (arm A/B) was 11.6 months/10.8 months (P=0.183). The overall response rate (ORR) and disease control rate (DCR) in arm A were higher than those in arm B with 64.3% versus 56.0% and 90.5% versus 84.5%, respectively. The 2-year overall survival (OS) rate (arm A/B) was 75.8% vs 68.6%. The median OS was not reached in the arm A while it was 35.5 in the arm B. Grade≥3 adverse events (AEs) occurred in 26.1% of patients, with 15.0% in arm A and 37.0% in arm B. The most commonly Grade≥3 AEs was neutropenia, rash, and leukopenia and there were no grade 5 AEs reported. A cost-effectiveness analysis showed an incremental cost-effectiveness ratio of $19,067 per QALY for mCapOX + CET, below the Chinese willingness-to-pay threshold ($ 41,188/QALY). **Conclusions:** The CAPCET study met its primary endpoint. mCapOX + CET demonstrated higher ORR/DCR and 2-year OS, with reduced toxicity, compared to mFOLFOX6 + CET. These findings support mCapOX + cetuximab as a clinically effective, better-tolerated, and cost-effective first-line treatment for left-sided RAS/BRAF wild-type mCRC within the Chinese economic framework, providing rationale for ongoing phase III evaluation (NCT06616259). Clinical trial information: NCT05022030. Prediction of hematotoxicity using CT-derived body composition in rectal cancer patients receiving immunotherapy-based total neoadjuvant therapy. First Author: Ruone Xu, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Immunotherapy-based total neoadjuvant therapy (iTNT) is a promising strategy to enhance complete response rates and facilitate organ preservation in locally advanced rectal cancer (LARC). However, it is linked to a considerable incidence of severe hematotoxicity, while reliable predictive biomarkers are lacking. Body composition, reflecting nutritional status, has been linked to treatment-related toxicity, but its relationship with iTNT toxicity remains unclear. This study aimed to investigate the association between body composition and hematotoxicity of iTNT and to develop a predictive model. **Methods:** A cohort of 204 LARC patients treated with iTNT was included for model development, with internal training and validation via five-fold cross-validation. Additionally, 43 metastatic rectal cancer patients treated with the same regimen served as the external validation cohort. Body composition parameters were obtained from pretreatment CT images at L3. LASSO regression was applied to select variables and four machine learning (ML) algorithms including logistic regression, random forest (RF), support vector machine (SVM), and extreme gradient boosting (XGBoost) were developed. **Results:** 33.8% of the discovery cohort experienced grade 3-4 hematotoxicity. Among baseline characteristics, skeletal muscle index (SMI) showed the most significant correlation with toxicity. The cut-offs for SMI, determined by optimal stratification, were 50.0 cm²/m² for males and 39.6 cm²/m² for females. Patients with low SMI had a higher incidence of severe toxicities ($P < 0.001$). Seven features were included in the ML models: age, body mass index (BMI), SMI, subcutaneous adipose tissue index (SATI), subcutaneous adipose tissue attenuation (SAT_HU), visceral adipose tissue index (VATI), and skeletal muscle attenuation (SM_HU). The predictive performance of the models is summarized in the following table. Overall, the SVM model showed the highest discriminative performance and robust generalizability. **Conclusions:** SMI was significantly associated with hematotoxicity during iTNT. A CT-based machine learning model was developed and validated to predict hematotoxicity, with the SVM model showing the most robust performance (AUC > 0.85) to guide clinical decision-making. Research Sponsor: None.

Cohort	Model	Accuracy	Sensitivity	Specificity	AUC
Internal validation	SVM	0.850 ± 0.024	0.849 ± 0.021	0.833 ± 0.027	0.881 ± 0.019
	RF	0.755 ± 0.037	0.749 ± 0.037	0.777 ± 0.032	0.803 ± 0.033
	Logistic regression	0.704 ± 0.048	0.672 ± 0.055	0.720 ± 0.048	0.730 ± 0.033
	XGBoost	0.796 ± 0.024	0.769 ± 0.038	0.788 ± 0.036	0.814 ± 0.027
External validation	SVM	0.821 ± 0.034	0.829 ± 0.026	0.800 ± 0.019	0.858 ± 0.029

An early on-treatment "coordinated inflammatory niche" plasma signature as a predictor of response in the SYLT026 trial: Cadonilimab combined with FOLFIRINOX and bevacizumab as first-line treatment for microsatellite-stable/proficient mismatch repair (MSS/pMMR) metastatic colorectal cancer (mCRC). First Author: Yi Yin, Fujian Cancer Hospital, Fujian Medical University Cancer Hospital, Fuzhou, China

Background: The SYLT026 trial is a phase II study investigating the efficacy and safety of cadonilimab (an anti-CTLA-4/PD-1 bispecific agent) combined with FOLFIRINOX and bevacizumab as first-line treatment for microsatellite-stable/proficient mismatch repair (MSS/pMMR) metastatic colorectal cancer (mCRC). We previously reported the promising outcomes at ASCO GI 2026. Updated survival data are reported here. The determinants of effective immune responses in MSS/pMMR mCRC remain elusive; the "Coordinated Inflammatory Niche" plasma signature was analyzed to predict the immune checkpoint inhibitor (ICI) response. **Methods:** Plasma samples from eligible patients were collected before ICI treatment and profiled using three non-overlapping protein arrays comprising 120 human cytokines (QAH-CAA-2000). These cytokines were integrated into an Inflammatory Niche Index (INI) using machine learning (random forest algorithm). Its predictive value for durable PFS ($>$ 12 months) was evaluated and compared with single markers. **Results:** Between November 16, 2023, and July 26, 2024, 20 patients were enrolled. The ORR was 100% (all partial responses). As of the data cutoff (December 31, 2025), the median follow-up was 24.4 months (IQR 22.4–26.4), the median PFS (mPFS) was 17.2 months (IQR 13.6–20.7), and the OS maturity rate was 20%. Seventeen patients underwent cytokine array analysis. Cytokine profiling identified a 9-protein panel (IP-10, eotaxin, MCP-1, IGFBP-3, MCP-4, TARC, IL-17, CCL28, I-TAC) that was significantly upregulated in responders. Further random forest modeling revealed the importance ranking of each protein, with TARC and IP-10 as the two most significant predictors, consistent with their most pronounced differential expression in the heatmap. The INI demonstrated superior predictive accuracy (AUC = 0.944) compared with IP-10 alone (AUC = 0.71, p = 0.03). Patients with a high INI (n = 9) had promising outcomes: mPFS was not reached (12-month PFS rate 90%), compared with 6.5 months in the low INI group (n = 8) (HR = 0.16, p = 0.001). Gene set enrichment analysis linked a high INI to a baseline tumor microenvironment enriched for NK T cell-related signatures, suggesting a biological basis for the niche. **Conclusions:** CTLA-4/PD-1 immunochemotherapy induced deep and durable responses in MSS/pMMR mCRC. An early on-treatment plasma proteomic signature (INI) powerfully identifies patients destined for durable benefit, offering a transformative tool for ultra-early, biology-guided patient selection in MSS/pMMR mCRC. Clinical trial information: NCT05839470. Research Sponsor: None.

Clinical implications of primary and metastatic tumor-informed clonal tracking for MRD assessment in oligometastatic colorectal cancer. First Author: Hyun Jin Bang, Chonnam National University Hwasun Hospital, Hwasun-Gun, South Korea

Background: While minimal residual disease (MRD) assays informed by primary tumor sequencing have demonstrated prognostic value in locally advanced colorectal cancer (CRC), the additive clinical benefit of combined tracking of metastatic-specific private variants in oligometastatic CRC (mCRC) remains unclear. We aimed to evaluate whether a combined primary and metastatic tumor-informed approach improves MRD detection sensitivity and prognostic accuracy following curative resection. **Methods:** We enrolled 24 patients who underwent curative resection for liver and/or lung oligometastases between 2023 and 2025. A comprehensive tumor-informed panel was designed based on variants identified through whole-exome sequencing (WES) of both primary and metastatic tissues. Serial plasma ctDNA was analyzed at three time points: post-metastasectomy (P1), post-adjuvant chemotherapy (P2), and at the time of recurrence (P3). The clinical performance of a primary tumor-only (PT-only) assay was compared with a combined primary and metastatic tumor-informed (PT+MT) assay. **Results:** The median age was 65 years (range 33–83), and 18 (75%) were male. Primary tumor locations included the colon (83%) and rectum (17%). Fourteen (58%) patients presented with synchronous metastases. Metastatic sites involved the liver (n = 13), lung (n = 10), or both (n = 1). At P1, P2, and P3, MRD positivity rates using the PT-only assay were 54%, 47%, and 100%, respectively. The PT+MT assay identified only one additional patient as MRD-positive at P1 compared to the PT-only assay. At a median follow-up of 29.2 months (IQR 22.6–32.7), 16 patients (67%) experienced recurrence. The PT-only assay showed significant prognostic impact (HR for ctDNA positivity: 4.53; 95% CI, 1.41–14.57; P = 0.006), which was comparable to the PT+MT assay (HR: 4.46; 95% CI, 1.38–14.38; P = 0.007). While PT+MT tracking did not significantly improve detection sensitivity at P1, it effectively captured clonal dynamics, showing a significant enrichment of metastatic-specific private variants in plasma at recurrence (26%, P3) compared to P1 (17%) and P2 (13%). **Conclusions:** Integrating metastatic-specific private variants into MRD tracking revealed distinct clonal dynamics but did not significantly enhance clinical sensitivity or prognostic performance compared to a primary tumor-informed assay in patients with oligometastatic CRC. These findings suggest that current MRD assay designs based on primary tumor sequencing remain a robust standard, even in the metastatic setting after curative resection. Research Sponsor: None.

Multiplexed immunohistochemistry (mIHC) analysis and clinical outcomes of nelmastobart in combination with trifluridine/tipiracil and bevacizumab in patients with refractory colorectal cancer (phase 1b/2). First Author: Soohyeon Lee, Korea University Anam Hospital, Korea University College of Medicine, Seoul, South Korea

Background: Colorectal cancer (CRC) patients who are refractory or intolerant to oxaliplatin- and irinotecan-based regimens face limited treatment options and poor prognoses. BTN1A1, a novel immune checkpoint protein involved in tumor progression and immune evasion, presents a potential therapeutic target. Nelmastobart, a first-in-class anti-BTN1A1 monoclonal antibody, is being evaluated in combination with trifluridine/tipiracil and bevacizumab in the Phase 1b/2 STCUBE-003 trial (NCT06873763). This study employs multiplexed immunohistochemistry (mIHC) to characterize the tumor microenvironment (TME) and identify biomarkers predictive of therapeutic response in CRC patients. **Methods:** Tumor tissues from 120 CRC patients were prescreened for BTN1A1 expression via immunohistochemistry (IHC). A total of 61 patients with a tumor proportion score (TPS) $\geq$50 were enrolled in the Phase 2 study. Pathologists used the TPS to guide patient selection, with TPS $\geq$50 as the inclusion criterion. Selected samples were analyzed using mIHC (Opal and CellDIVE), utilizing a 20-protein panel relevant to cancer immunology. Protein co-expression and the spatial distribution of immune and malignant cells were evaluated to assess tumor-immune interactions. **Results:** Among 120 tumor samples analyzed by IHC, 78 (65%) exhibited TPS $\geq$50. Sixteen patients (13%) showed no expression (TPS 0), and 26 (21.6%) had low to medium expression (1 $\leq$ TPS $\leq$ 49). This expression profile aligns with previous CRC studies (STCUBE-001 and STCUBE-IIT-001). In the initial efficacy evaluation of 39 patients with TPS $\geq$50, 2 (4.8%) achieved a partial response (PR), 27 (69.2%) showed stable disease (SD), and 8 (20.5%) had progressive disease (PD). High BTN1A1 expression was significantly associated with a higher clinical response rate. mIHC analysis further revealed that BTN1A1 expression correlated with Ki-67, SLFN11, and YAP1, as well as distinct patterns of $CD8^+$ T-cell infiltration. **Conclusions:** BTN1A1 is consistently and highly expressed in refractory CRC (median TPS 50). mIHC analysis confirms that BTN1A1 is closely integrated with key immune checkpoints and tumor markers within the TME. Initial clinical results, which show disease control in the majority of patients, particularly within the TPS $\geq$50 population, support the utility of BTN1A1 as a predictive biomarker for Nelmastobart combination therapy. These findings justify the ongoing biomarker-driven Phase 2 portion of the STCUBE-003 trial. Clinical trial information: NCT06873763. Research Sponsor: None.

Phase 1, FIH study of cabotamig, a TCE CDH17 X CD3, in CDH17-expressing GI malignancies. First Author: Roland Ching-Yu Leung, Department of Medicine, Queen Mary Hospital, The University of Hong Kong, Hong Kong, China

Background: Cadherin-17 (CDH17) is a specific cancer target; aberrant expression is up to >95% in GI tumors (stomach, pancreas, bile duct, rectum, small bowel and colon). Cabotamig (ARB202) is a humanized, IgG4, T-cell engaging antibody (TCE) that binds to CDH17 and CD3 T-cells forming synapse to aid activation. This study evaluated the safety, pharmacokinetics (PK), biomarkers, and anti-tumor activity of cabotamig in patients (pts) with CDH17+ gastrointestinal (GI) cancers. **Methods:** Pts $\geq$18 years with locally advanced or metastatic CDH17+ GI cancers refractory to therapies, measurable disease and ECOG 0/1 were enrolled. MABEL calculations per FDA TCE guidance were used (0.0003 mg/ml to 1.0 mg/ml by $^1/_2$ log increments). For safety given multi log difference in CDH17 density, an initial dose of 1/10 was given 3 days before the remaining 9/10. In the 4th cohort, patients with stable disease were given additional doses (7/10 cohort 4-6). Cohort was split into colorectal cancers (CRC) and non-CRC groups given the differences in CDH17 levels and symptoms. After the 7th cohort dosing proceeded to dose optimization. Data cutoff 02142025. **Results:** Pts (CRC 15/22 total) received cabotamig at 1/10 dose (0.00003-0.032 mg/kg) followed by 9/10 dose (0.0003 to 0.32 mg/kg) across 7 cohorts with the max. of 37.8(3.8/34) mg. The max. tolerated dose was not reached. Dose responsive cytokine release syndrome (CRS) symptoms were evident with more symptoms between the 1/10 and 9/10 dose and with increasing intensity with escalation. Treatment related AEs (CRS 17, fever 16, nausea 7, diarrhea 5, vomiting 5 fatigue 3 chills 2) were reported with 1st set or 2nd infusions and occurred in all patients without pre-corticosteroids in the 4th cohort and intensified even with premed up to the 7th cohort. PK data indicated dose proportionality and faster-than-typical IgG4 clearance. Anti-tumor biomarker activity, primarily CEA, but when present included other CA markers, showed a dose response (increase then a decrease to levels below baseline, consistent with target cell lysis) with a peak response between the 5th and 6th cohorts. **Conclusions:** This first-in-human (FIH) study (NCT05411133) targeting CDH17 in GI cancer pts showed a tolerable safety profile for cabotamig up to 0.32mg/kg. Step-up dosing appeared to mitigate dose responsive on-target tumor CRS and the lack of persistent GI toxicities indicated minimal on-target normal GI mucosal effects. Dose responsive biomarker anti-tumor activity of cabotamig was observed. Clinical trial information: NCT05411133. Research Sponsor: None.

The CONVERGE study: A phase II, single-arm trial of adebelimab combined with targeted therapy and liposomal irinotecan-based chemotherapy for conversion surgery in unresectable MSS colorectal cancer liver metastases. First Author: Wenhui Yang, Department of Gastroenterology, Shanxi Province Cancer Hospital/Shanxi Hospital Affiliated to Cancer Hospital, Chinese Academy of Medical Sciences/Cancer Hospital Affiliated to Shanxi Medical University, Taiyuan, China

Background: Liver metastasis is a key poor prognostic factor for colorectal cancer (CRC). Microsatellite stable (MSS) CRC predominates and is poorly responsive to single-agent immunotherapy. Only 10%–20% of patients with initially unresectable MSS colorectal cancer liver metastases (CRLM) are eligible for upfront curative resection, and conventional chemo-targeted therapy yields a conversion resection rate of merely 15%–30%. This phase II study evaluated the efficacy and safety of adebelimab (a PD-L1 inhibitor) plus molecularly stratified targeted therapy and liposomal irinotecan-based chemotherapy for unresectable MSS CRLM, focusing on hepatic metastatic lesion control (ChiCTR2600117031). **Methods:** This single-center, open-label phase II trial enrolled 45 patients with unresectable MSS CRLM (ECOG PS 0-1, no prior systemic anti-tumor therapy). Patients received adebelimab (1200mg IV, Q2W) + stratified targeted therapy (cetuximab for RAS/BRAF wild-type left-sided tumors; bevacizumab otherwise) + liposomal irinotecan-based chemotherapy (Q2W) for up to 12 cycles. Primary endpoint: conversion-to-resection rate. Secondary endpoints: ORR, DCR, R0 resection rate, hepatic metastasis pathological response, and safety (NCI-CTCAE v5.0). Efficacy was assessed per RECIST v1.1. **Results:** As of January 20, 2026, 42 patients were included in baseline analysis (median age 57.6$\pm$11.1 years, 64.3% male; mean hepatic metastasis diameter 37.21$\pm$19.00 mm, max 82.79 mm). Among 35 efficacy-evaluable patients, ORR was 45.7% (95% CI: 28.8%–63.4%) and DCR was 88.6% (95% CI: 73.3%–96.8%). Fourteen patients underwent surgery (conversion rate 45.2%, 95% CI: 27.3%–60.0%), all completing simultaneous resection of hepatic metastases and primary tumors. Of these 14 patients, 5 (35.7%) achieved hepatic TRG 0 (complete pathological regression) and 12 (85.7%) achieved R0 resection (95% CI: 49.2%–95.3%). For safety, 95.2% (40/42) of patients had AEs. Common ($\geq$10%) all-grade AEs were mainly hematological (leukopenia 23.8%, myelosuppression 21.4%). Grade 3 AEs were rare (predominantly leukopenia 14.3%), and no grade 4 AEs occurred. No any-grade immune-related AEs were reported. **Conclusions:** Adebelimab combined with molecularly stratified targeted therapy and liposomal irinotecan-based chemotherapy shows substantial efficacy and favorable safety for unresectable MSS CRLM, with excellent hepatic metastasis control. Its high conversion-to-resection rate and 35.7% hepatic TRG 0 rate confirm potential for deep pathological response. This regimen warrants further investigation as a promising conversion therapy for unresectable MSS CRLM. Genomic sequencing of successfully converted patients is ongoing to elucidate therapeutic mechanisms. Clinical trial information: ChiCTR2600117031. Research Sponsor: Hengrui Pharma.

Association of concurrent GLP-1 receptor agonist use with survival outcomes in patients with metastatic colorectal cancer receiving immune checkpoint inhibitors. First Author: Shalin Rawal, NYMC at St. Mary's General Hospital and Saint Clare's Health, Denville, NJ

Background: Metabolic status and systemic inflammation are increasingly recognized as important modifiers of immune checkpoint inhibitor (ICI) response. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) exhibit anti-inflammatory and immunomodulatory properties and are widely used in diabetes and obesity. However, their clinical impact on immunotherapy outcomes in metastatic colorectal cancer (mCRC) remains unclear. **Methods:** We conducted a retrospective observational cohort study using the TriNetX Global Collaborative Network, including electronic health records from 170 healthcare organizations between 2015 and 2025. Adults with mCRC who received at least one ICI were identified. Patients prescribed GLP-1 RAs within six months before or after ICI initiation were compared with non-exposed controls. Patients with prior bariatric surgery were excluded. Cohorts were balanced using 1:1 propensity score matching for demographics, metabolic conditions, and major comorbidities. Primary endpoint was all-cause mortality at 1, 3, and 5 years. Secondary outcomes included pneumonia, heart failure exacerbation, and major abdominal surgical procedures. Survival analyses were performed using Kaplan–Meier methods and Cox proportional hazards models. **Results:** Among 8,304 eligible patients, 148 received GLP-1 RAs. After propensity matching, 138 patients were included in each cohort with well-balanced baseline characteristics. At 1 year, mortality was lower in the GLP-1 cohort (27.5% vs 40.6%), corresponding to a 32% relative risk reduction (RR 0.68, 95% CI 0.49–0.95) and reduced hazard of death (HR 0.67, 95% CI 0.43–1.03). This association persisted at 3 years (27.5% vs 41.3%; RR 0.67, 95% CI 0.48–0.93; HR 0.68, 95% CI 0.45–1.05) and 5 years (28.3% vs 42.0%; RR 0.67, 95% CI 0.49–0.93), with higher 5-year survival probability (50.5% vs 41.5%). Secondary outcomes favored GLP-1 exposure, including lower incidence of pneumonia (10.9% vs 17.4%; HR 0.58) and fewer heart failure exacerbations (23.9% vs 31.9%; HR 0.75). Rates of major abdominal surgical procedures were numerically lower in the GLP-1 cohort. **Conclusions:** In this large real-world cohort, concurrent GLP-1 RA exposure was associated with clinically meaningful and durable survival benefit in mCRC patients receiving ICIs, without increased adverse clinical outcomes. These findings suggest a potential immunometabolic interaction and support prospective evaluation of GLP-1–based strategies as adjunctive modifiers of immunotherapy response. Research Sponsor: None.

3606 Poster Session

Dynamics of circulating monomeric C-reactive protein (mCRP) to predict outcomes with first-line alternating oxaliplatin-based chemotherapy and nivolumab in metastatic microsatellite-stable (MSS) colorectal cancer (CRC). First Author: Anniken Joerlo Fuglestad, Akershus University Hospital, Lorenskog, Norway

Background: Elevated CRP levels at CRC diagnosis are consistently associated with poor outcomes, suggesting a tumor-promoting and potentially immuno-suppressive inflammatory state. The clinically assessed CRP is a pentameric protein that can dissociate to mCRP, an isoform with pro-inflammatory effects on innate immune responses. The randomized METIMMOX trial (NCT03388190) evaluated potentially immunogenic short-course oxaliplatin-based chemotherapy (FLOX) alternating with nivolumab in previously untreated, unresectable metastatic MSS CRC. We investigated whether oxaliplatin-induced immunogenicity is measurable as an early change in circulating mCRP and may identify patients more likely to derive clinical benefit from sequential nivolumab. **Methods:** Patients were randomly assigned to the control group of FLOX (oxaliplatin, 5-fluorouracil, folinic acid) Q2W or the experimental group of alternating 2 cycles each of FLOX Q2W and nivolumab Q2W with prespecified break periods. The primary endpoint was progression-free survival (PFS). This *post hoc* analysis included 29 patients from the experimental group, of whom 28 had paired mCRP and clinical CRP measurements from baseline (Pre) and post second FLOX cycle (Post) timepoints. CRP was measured by standard immunoturbidimetry. Plasma mCRP was separated from CRP by 100-kDa filtration and quantified by targeted nano LC-timsTOF Pro mass spectrometry with AQUA standards. CRP at the reference limit 5.0 mg/L and mCRP at the median value 45 ng/mL were used as cutoff values. Changes from Pre to Post were denoted ΔmCRP and ΔCRP and categorized as ³0 (stable/increase) and < 0 (decrease). **Results:** Low Pre and low Post CRP were associated with prolonged PFS (log-rank p = 0.080 and p = 0. 002, respectively), while ΔCRP showed no association (log-rank p = 0.57). By contrast, a significant association was observed for ΔmCRP (log-rank p = 0.015), where median PFS was longer among the ΔmCRP ≥0 population (16.4 months [95% CI 8.8-23.9]; n = 15) *versus* the ΔmCRP < 0 population (9.2 months [95% CI 3.6-14.8]; n = 13). Notably, patients with the combination ΔCRP < 0 and ΔmCRP ≥0 (n = 8) had an undefined median PFS (≥41.6 months) at data cutoff, compared to median PFS 9.2 months (95% CI 1.4-16.9; n = 20) for all other patients (log-rank p = 0.022). **Conclusions:** Patients with metastatic MSS CRC who exhibited an increase in mCRP and decrease in clinical CRP following the initial 2 chemotherapy cycles of first-line oxaliplatin-based chemotherapy alternating with nivolumab had markedly prolonged PFS. Moreover, increased PFS was observed alongside increased circulating mCRP regardless of change in CRP. These data suggest an early increase in mCRP may be an indicator of immunotherapy-associated efficacy. Clinical trial information: NCT03388190. Research Sponsor: None.

3607 Poster Session

The SERPENTINE trial: A phase II clinical study decoding immune responses by scRNA-seq and TCR-seq analysis in patients with MSS metastatic colorectal cancer (mCRC) with and without liver metastases treated with durvalumab and tremelimumab. First Author: Iosune Baraibar, Department of Medical Oncology, Vall d'Hebron Institute of Oncology (VHIO), Vall d'Hebron University Hospital, Barcelona, Spain

Background: Immune checkpoint inhibitor (ICI) therapy aims to instruct immune cells to efficiently recognize and eliminate cancer cells. It has shown efficacy in MSI colorectal (CRC), and, although there is no approval yet, a subset of patients with MSS CRC included in clinical trials respond to ICI, indicating a significant knowledge gap in our current understanding of immunological mechanisms in MSS CRCs. The relationship between the cellular and molecular responses to ICI in the tumor microenvironment (TME) and the clinical outcome remains poorly understood. We sought to address this gap in understanding through a series of high-throughput functional genomics analyses. **Methods:** Patients (pts) with refractory MSS CRC were treated with durvalumab (Dur) 1500mg plus tremelimumab (Trem) 300mg at Week 0, followed by Dur 1500 mg Q4W. We characterized the cellular makeup of the metastatic TME using single-cell RNA-seq, and cataloged T-cells clonotypes within metastases and in the blood using single-cell and deep TCR-seq. We collected data for each patient before and upon treatment initiation to explore the dynamic changes of the TME and blood in response to ICI. To facilitate direct comparisons between metastatic and primary TMEs, we integrated our dataset with an external single-cell RNA-seq dataset from primary CRC tumors. **Results:** 24 pts were included in the analysis (18 with no liver metastases (NLM), 6 with liver metastases (LM)). Around 200,000 single-cell profiles were collected from biopsies taken from 6 pts with LM and 10 pts with lung metastases. Disease Control Rate (DCR) was 39% for MSS CRC without LM (2 PR + 5 SD) and 0% for those with LM (p=0.13). Robust gene expression changes within the immune compartment of the TME were observed upon treatment, irrespective of overall treatment outcome, yet specific biological programs were differentially altered across patient response groups. Differences in the composition of TMEs in the lung and liver metastases were found with an enrichment of T regulatory and IFN-responder CD4 populations in the lung vs more CD8+ T cell subtypes in the liver. Tumor TCR analysis revealed that, following ICI treatment, liver metastases displayed a high diverse TCR repertoire, whereas lung metastases were less diverse and showed marked clonal expansion, suggesting greater T cell activity within the lung lesions (p=0.035). **Conclusions:** Prospective deep immune repertoire profiling detected profound differences in TME according to dissemination patterns, which might explain differences in treatment outcomes. Despite low overall efficacy with Dur and Trem in MSS patients, a trend to better response rate and DCR was observed in pts without LM. We propose immune cell tracking as powerful tool to quantify the efficacy of ICI in real time. Clinical trial information: NCT06680739. Research Sponsor: Astra Zeneca.

Liver transplantation (LT) in liver limited metastatic colorectal cancer (CRC): Insights and opportunities. First Author: Jonathan W. Lee, Weill Cornell Medical College, New York, NY

Background: Liver transplantation (LT) for liver limited metastatic colorectal cancer (LL-mCRC) remains underutilized. Reasons for transplant ineligibility are not well described and the acceptance of this procedure for mCRC remains limited. Herein, we describe our initial experience with LT in patients with LL-mCRC. We characterize patient outcomes, characterize the pattern of failure for patients undergoing LT evaluation, and describe the prognostic implication of lymphadenectomy in LT evaluation. **Methods:** Patients with LL-mCRC potentially eligible for LT were identified, discussed in multidisciplinary tumor boards and liver transplantation clinics, and managed. The Weill Cornell Liver Transplant institutional database was queried to identify patients evaluated for LT, those who were transplanted, and those who were not. Demographic, surgical data, and clinical outcomes abstracted from medical record. **Results:** Between 7/2020 and 3/2025, 20 patients with LL-mCRC were evaluated for LT. Median age (range) 55 years (29-63); N=10 (50%) white; N=18 (90%) male. All had adenocarcinoma histology with N=14 (70%) left sided primary disease. At diagnosis, N=11 (55%) had ≥1 liver lesion >5.5cm and median CEA (range) was 200 (4.8-6945). The most common mutations were APC (60%), KRAS (55%), TP53 (45%), and PIK3CA (35%). N=6 (30%) had a LT with a median time from diagnosis to transplant of 23.7 months (mo) (range 16-42). The median overall survival (OS) from LT is 64.5 mo (range 22-87). N=5 (83%) are alive with a median follow up of 67 mo (range 22-87). N=3 patients had recurrent disease with a median time to recurrence of 3 mo (range 2-9), 2 in lungs, and 1 retrocrural lymph nodes. At this time, N=4 (67%) patients have no evidence of disease, and one with retrocrural lymph node disease is responding to treatment. The single patient who underwent LT and died was portal lymph node positive at the time of transplant and had an early recurrence (at 2 mo post-transplant). For the 14 patients who were evaluated for transplant, but did not undergo transplant, their mOS is 28 mo (range 13-44). Reasons why these patients did not undergo LT are shown in Table 1. The majority failed transplant evaluation due to progressive disease (lung 43%, liver 21%, abdomen 14%). Positive portal lymphadenectomy was a poor prognostic characteristic, with all 3 patients deceased. **Conclusions:** LT is a treatment option that confers durable remission and improved OS in LL-mCRC. Recurrent disease after transplant is generally controllable with local treatment modalities. Patient selection is critical in identifying appropriate LT candidates. Portal lymphadenectomy is prognostic and should be considered in all transplant evaluations. Research Sponsor: None.

Refining clinical trial eligibility for minimal residual disease in patients with colorectal cancer: The MD Anderson INTERCEPT experience. First Author: Soumya Shekhar, Department of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Detection of circulating tumor DNA (ctDNA) is prognostic for recurrence after completion of curative-intent therapy for patients (pts) with colorectal cancer (CRC). Our MD Anderson INTERCEPT platform enrolls ctDNA(+) CRC pts onto matched clinical trials, with the goal of eradicating minimal residual disease (MRD) and curing more pts with CRC. To gain insights on how to identify CRC pts most likely to have true MRD, we retrospectively reviewed the role of non-specific radiographic abnormalities in forecasting CRC recurrence. **Methods:** For this retrospective review of CRC pts included in ctDNA intervention trials (Table) from 1/2019-12/2025, MRD at baseline was defined as (1) having no radiographically evident disease at time of study enrollment and (2) detection of ctDNA on an MRD assay (Signatera). ctDNA levels were quantified as mean tumor molecules (MTM) per milliliter (mL) plasma. Radiographic sites of disease progression on clinical trials were compared with pre-treatment imaging. Median recurrence-free survival (RFS) was estimated using Kaplan Meier and compared with Cox regression. **Results:** 54 pts with definitively treated CRC prior to subsequent ctDNA(+) were enrolled across 4 trials (Table); 45 pts (83%) had stage IV disease. No pts had radiographically evident CRC at trial start. Median ctDNA levels were 0.45 MTM/mL (IQR 0.12 – 2.4). After a median follow up of 6.4 months (IQR, 3.5-9.5), 42 (78%) pts had recurred after treatment on a ctDNA intervention trial. Median RFS was 8.1 months (95% CI 4.4 - 9.4). Sites of recurrence were liver (N=20, 48%), lung (N=13, 31%), lymph nodes (N=10, 24%), and peritoneum (N=3, 7%). Upon retrospective review, minute but discernible lesions were identified at the sites of recurrence in 25 (60%) of the pts who had a recurrence on MRD trials. At eligibility evaluation these were characterized as "benign" in 14 (56%) or as "post-procedural" in 11 (44%) of the cases. The presence of indistinguishable CRC deposits at the start of the trial was associated with inferior RFS (4.2 vs 9.3 months; HR 1.96 (95% CI 1.04-3.70; p = 0.04). **Conclusions:** Subclinical radiographic findings may confound true identification of pts with CRC MRD for clinical trials. Optimizing definitions of radiographically detectable disease is warranted in order to ensure homogenous populations of CRC that are the most likely to benefit from novel MRD therapies. Long-term survival and biomarker analysis of neoadjuvant chemoradiotherapy with or without PD-1 antibody sintilimab in pMMR locally advanced rectal cancer: A randomized clinical trial. First Author: Weiwei Xiao, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University, Guangzhou, Guangdong, China

Background: We previously reported that adding sintilimab to neoadjuvant chemoradiotherapy (NACRT) significantly improved the complete response (CR) rate compared to NACRT in mismatch repair-proficient (pMMR) locally advanced rectal cancer (LARC) patients (44.8% vs. 26.9%; P = 0.031). Here, we present the long-term survival outcomes and exploratory biomarker analyses from this randomized trial. **Methods:** Between June 2020 and July 2022, a total of 134 patients with pMMR LARC were randomly assigned (1:1) to the experimental arm (NACRT plus sintilimab, n = 67) or the control arm (NACRT, n = 67). The primary endpoint was CR rate. Secondary endpoints included disease-free survival (DFS) and overall survival (OS). Survival analysis was estimated using the Kaplan-Meier method and compared using the log-rank test. Hazard ratios (HR) were calculated using the Cox proportional hazards model. Baseline tumor and blood samples were collected for whole exome sequencing. **Results:** With a median follow-up of 48.5 months, the experimental arm exhibited significantly superior 3-year DFS compared to the control arm (91.0% vs. 77.6%; HR = 0.37, 95% CI: 0.14-0.94, log-rank P = 0.030). Analysis of failure patterns showed lower rates of both local recurrence (1.5% [1/67] vs 3.0% [2/67] and distant metastases (9.0% [6/67] vs. 19.4%[13/67]) in the experimental arm. Notably, liver metastases were more frequent in the control arm (1.5% [1/67] vs. 9.0% [6/67]). Subgroup analyses identified a pronounced DFS benefit from combination therapy in patients aged $>$ 50 years (HR = 0.24, 95% CI: 0.07-0.86, P = 0.029) and those with extramural venous invasion (EMVI)-positive tumors (HR = 0.26, 95% CI: 0.09-0.81, P = 0.020). Notably, achieving a CR was consistently associated with a trend toward prolonged DFS in both the experimental (log-rank P = 0.129) and control arms (log-rank P = 0.145). In exploratory biomarker analysis, patients harboring MUC16 mutations in the experimental arm exhibited a trend toward improved DFS, although statistical significance was not reached (log-rank P = 0.318); conversely, no such trend was observed in the wild-type population (log-rank P = 0.496). The 3-year OS rates were 97.0% in both groups (log-rank P = 0.977). **Conclusions:** Adding PD-1 antibody to NACRT conferred a superior DFS benefit compared to NACRT in patients with pMMR LARC, particularly in older patients and those with EMVI-positive tumors, and potentially influenced the pattern of metastasis. MUC16 mutations warrant further investigation as a potential predictive biomarker for sensitivity to the combination therapy. Clinical trial information: NCT04304209. Dual-microbial signature as a predictor of postoperative colorectal cancer recurrence. First Author: Pancheng Chen, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Current surveillance strategies for postoperative recurrence in colorectal cancer predominantly depend on tumor markers, imaging modalities, and endoscopic procedures; however, these approaches are challenged by suboptimal diagnostic accuracy. Consequently, the identification and validation of novel biomarkers represent an urgent clinical necessity. Sensitive microbiome-based approaches for postoperative risk stratification, surveillance optimization, and early recurrence detection may substantially influence clinical decision-making and resource allocation for colorectal cancer patients. **Methods:** This cohort study included CRC fecal and tumor samples from four independent cohorts (n = 615) in the Fudan University Shanghai Cancer Centre (Shanghai, China) between January 2017 and December 2020, with follow-up through December 2024. Fecal samples from the discovery (n = 250), training-validation cohorts (n = 153), as well as tumors with paired adjacent normal tissues from the investigation cohort (n = 244), were subjected to multi-omics analyses. We developed prediction models of disease-free survival by additionally incorporating dual-microbial signature including the abundance of Roseburia and Bifidobacterium. Both models were evaluated by internal validation cohort, and visual nomograms of prediction models were constructed accordingly. **Results:** We found that the combined high abundance of Roseburia and Bifidobacterium was associated with favorable outcomes (P = 0.039), especially in male (P = 0.018) and early-onset colorectal cancer (P = 0.047). Integration of clinical variables with a dual-microbial signature achieved a mean AUC $>$ 0.8 for recurrence prediction. A high combined abundance of Roseburia and Bifidobacterium was linked to reduced enrichment of primary bile acid biosynthesis pathways and increased enrichment of propanoate metabolism pathways. **Conclusions:** This study proposes a novel strategy for CRC recurrence risk assessment and highlights the potential of gut microbiota as a tertiary preventive approach in CRC management. However, the proposed model has not yet been implemented in clinical practice and requires validation in large, multicenter prospective cohorts before clinical translation. Research Sponsor: None.

Targeting the Warburg effect: Mitochondrial metabolic modulation with intermittent fasting during neoadjuvant chemoradiation in rectal cancer compared with standard neoadjuvant chemoradiation and total neoadjuvant therapy. First Author: Krithikaa Sekar, Healthcare Global Enterprises limited, Bengaluru, India

Background: Cancer cells demonstrate metabolic inflexibility characterized by glycolytic dependence and dysfunctional mitochondrial oxidative phosphorylation [Warburg Effect]. Fasting and glucose restriction induce a metabolic shift toward mitochondrial fatty acid oxidation and ketone utilization in normal cells, while cancer cells are unable to adapt, resulting in increased oxidative stress and radio-sensitization. We evaluated whether inducing a fasting-mimicking metabolic state during neoadjuvant chemoradiation improves pathological complete response (pCR) rates in rectal cancer compared with total neoadjuvant therapy (TNT) and standard neoadjuvant chemoradiation (nCRT). **Methods:** 90 patients with locally advanced rectal adenocarcinoma were analyzed (30 per group). All patients had cT3N+ disease. Radiotherapy was delivered using IMRT/IGRT or adaptive techniques, receiving long-course radiotherapy (50.4 Gy in 28 fractions) with concurrent capecitabine. Group 1 received nCRT under a fasting-mimicking metabolic state using a structured low-carbohydrate diet [Non-Calorie Restricted] with $\geq$14 hours of daily fasting, titrated using continuous glucose monitoring [CGM] to achieve 16–17 hours per day with blood glucose levels $<$90 mg/dL. Group 2 received TNT consisting of nCRT followed by CAPEOX. Group 3 received standard nCRT without dietary intervention. The primary endpoint was pCR (ypT0N0) at surgery. pCR rates were compared between groups using the chi-square test or Fisher's exact test, as appropriate, with a two-sided p value $<$0.05 considered statistically significant. **Results:** Baseline characteristics were balanced across groups; all patients had cT3N+ disease. Median age was 55 years, with all adenocarcinoma histology. pCR rates were 93.3% (28/30) in the fasting-state nCRT group, 73.3% (22/30) in the TNT group, and 33.3% (10/30) in the standard nCRT group. Fasting-state nCRT was associated with significantly higher pCR rates compared with standard nCRT (χ^2=25.2, df=2; p$<$0.001). TNT was also superior to standard nCRT (p=0.004). The difference between fasting-state nCRT and TNT showed a strong numerical trend but did not reach statistical significance (p=0.08). **Conclusions:** Fasting-state metabolic modulation during neoadjuvant chemoradiation was associated with a striking increase in pCR rates. Mitochondrial stress induced by glucose restriction may enhance tumor radio-sensitivity through increased reactive oxygen species and impaired metabolic compensation. Precision-guided fasting represents a promising, low-cost therapeutic strategy warranting prospective larger cohort validation. Clinical trial information: CTRI/2024/10/075843. Research Sponsor: HCG Research Fund.

Comparison	pCR	p-value
Fasting-state nCRT	93.3% (28/30)	$<$ 0.001
TNT	73.3% (22/30)	0.004
Standard nCRT	33.3% (10/30)	0.08

Predicting neoadjuvant chemoradiotherapy response and postoperative recurrence in locally advanced rectal cancer using a preoperative large language model. First Author: Xiaoxi Chen, Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing, China

Background: Neoadjuvant chemoradiotherapy (nCRT) is standard for locally advanced rectal cancer (LARC), yet responses are heterogenous and early identification of responders remains challenging. We developed a Transformer-based large language model that analyzes fragment-level patterns in circulating cell-free DNA (cfDNA) to predict pathological complete response (pCR) and postoperative recurrence risk independently of somatic mutation calling. **Methods:** A total of 510 plasma samples were collected from 102 LARC patients at five perioperative time points. The model was trained on post-nCRT cfDNA data from a training cohort (N = 62) to predict pCR, evaluated in an internal validation cohort (N = 40) and an external validation cohort (N = 96). Associations between model prediction scores, nCRT response, and recurrence-free survival (RFS) were assessed across time points. Fragment-level features contributing to model predictions were analyzed to provide biological interpretability. **Results:** The model demonstrated robust predictive performance, with AUCs of 0.909 (95% confidence interval [CI]: 0.812-1.000) in the training cohort, 0.903 (95% CI: 0.785-1.000) in the validation cohort, and 0.835 (95% CI: 0.754-0.916) in the external cohort. Patients achieving pCR had significantly higher prediction scores than non-pCR patients (Wilcoxon p $<$ 0.001), and scores inversely correlated with tumor regression grade (Jonckheere-Terpstra test p $<$ 0.001). At the predefined cutoff corresponding to 95% specificity in the training cohort, sensitivities were 0.73, 0.64, and 0.44 across datasets. High post-nCRT and post-surgical prediction scores were associated with improved RFS (log-rank p = 0.012 and p = 0.024, respectively), and all relapsed patients had consistently low post-nCRT scores. The top 1% of cfDNA fragments, ranked by model importance, were predominantly 50-100 bp with ~ 40% GC content, and the proportion of subnucleosomal particles was significantly higher in pCR versus non-pCR samples, providing biological insights into features driving the model. **Conclusions:** We developed a robust, mutation-independent framework for predicting nCRT response and postoperative recurrence risk in LARC, supporting individualized treatment decisions and post-surgical surveillance strategies. Research Sponsor: Natural Science Foundation of Hunan Province; 2024JJ5568.

Association between circulating tumor DNA and local tumor regrowth and distant metastasis during nonoperative management in stage I–III rectal cancer. First Author: Kentaro Ochiai, Department of Colon and Rectal Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: During nonoperative management (NOM) for rectal cancer after a clinical complete response (cCR) or near-CR (nCR), 25–30% develop local regrowth and 5–10% develop distant metastasis, highlighting the need for improved risk stratification and surveillance. Circulating tumor DNA (ctDNA) has emerged as a prognostic biomarker, but its utility in NOM decision making remains undefined. **Methods:** We retrospectively studied 110 patients with stages I-III, microsatellite stable rectal adenocarcinoma achieving cCR/nCR after neoadjuvant therapy (2020-2024) managed with NOM and tumor-informed ctDNA testing in the INTERCEPT program (Signatera Exome). We assessed longitudinal ctDNA status during NOM and the first post-treatment ctDNA in relation to local regrowth and/or distant metastasis (Kaplan–Meier/log-rank; Fisher's exact). We also evaluated per-sample accuracy for events occurring within ±90 days of each blood draw. **Results:** Over a median follow-up of 25 months, 23 (20.9%) patients developed local regrowth and 12 (10.9%) developed distant metastases (Table 1). Patients with ever positive longitudinal ctDNA had an associated worse 2-year regrowth-free survival (41.7% vs 83.9%, P=0.0002) and metastasis-free survival (41.7% vs 94.9%, P<0.0001) than those with persistently negative ctDNA. Among patients with an evaluable first post-treatment ctDNA result (within 180 days post treatment; n=72), those with a positive result had an associated lower regrowth-free survival (P = 0.0006) and metastasis-free survival (P < 0.0001). In per-sample analysis (n=669), ctDNA showed low sensitivity and high specificity for local regrowth (41.4% and 94.3%) and higher sensitivity and specificity for distant metastasis (73.8% and 97.4%). Twenty-two of 23 patients with local regrowth underwent salvage surgery; ctDNA positivity at local regrowth was associated with more advanced pathological T stage (66.7% of ypT3–4 vs 15.4% of ypT0–2, P=0.01). **Conclusions:** During NOM for rectal cancer, ctDNA may be used to identify a small subgroup at high risk of local regrowth and/or distant metastasis. However, many local regrowth occurs despite persistently negative ctDNA, consistent with limited sensitivity. Negative ctDNA results should therefore not prompt de-escalation of endoscopic and radiologic surveillance when a NOM strategy is used. Research Sponsor: None.

Overall rates of local regrowth and distant metastasis.

	Local regrowth (n=23)[a]	P	Distant metastasis (n=12)	P
Longitudinal ctDNA		<.0001		<.0001
Persistently negative (n=95)	14/95 (14.7%)		3/95 (3.2%)	
Ever positive (n=15)	9/15 (60.0%)		9/15 (60.0%)	
First post-treatment ctDNA[b]		0.005		<.0001
Negative (n=67)	15/67 (22.4%)		5/67 (7.5%)	
Positive (n=5)	4/5 (80.0%)		4/5 (80.0%)	

[a]Two had synchronous and 5 had metachronous distant metastasis.
[b]Within 6 months post treatment, n = 72.

Minimal residual disease (MRD) assessment by circulating tumor DNA (ctDNA) to stratify recurrence risk and adjuvant treatment benefit in a real-world colorectal cancer (CRC) cohort. First Author: Mariem Galuia, AdventHealth Cancer Institute, Orlando, FL

Background: ctDNA detection following curative surgery is known to predict recurrence in patients (pts) with stage II-III CRC. We investigate ctDNA dynamics in relation to clinical outcomes and their real-world impact on treatment decisions among pts with resected CRC. **Methods:** Based in a large community hospital system, we conducted a retrospective analysis of a prospectively maintained database inclusive of 407 pts with resected stage II-IV CRC. ctDNA was longitudinally quantified at MRD (2-12 weeks post-op) and surveillance timepoints (tp) using a clinically validated, personalized, tumor-informed 16-plex mPCR-NGS assay. Primary endpoint was the correlation between ctDNA status and disease-free survival (DFS) and overall survival (OS). Secondary objective was to evaluate its impact on treatment decisions. Survival distribution was analyzed by Kaplan-Meier Method. Multivariable Cox proportional hazards models were applied to adjust for clinicopathological covariates: age, gender, T, N, high risk features, obstruction, perforation, KRAS, BRAF, MMR. **Results:** Of 407 pts, 303 had complete evaluable data for analysis at cutoff 12/5/2025. After median follow-up of 29.6 months (mo), N=2342 ctDNA plasma levels were analyzed: 2 stage I, 119 stage II, 170 stage III, 12 stage IV. ctDNA at MRD tp was available for 259 pts (86%): 99 stage II, 144 stage III. ctDNA was negative at MRD tp in 211/259 (MRD-), positive in 48/259 (MRD+). Of 303 pts,180 (60%) received adjuvant chemotherapy (ACT): 38 MRD+, 118 MRD-. 123 (40%) were observed: 9MRD+, 93 MRD-. MRD positivity was significantly associated with inferior DFS in all stages combined (HR = 13.4, 95% CI: 7.64–23.64, p<0.0001) and in all stage-stratified subgroups. Multivariate analysis confirmed ctDNA-positivity to be the most significant prognostic factor associated with DFS when compared with clinicopathologic factors. In MRD+ subgroup, pts with transient ctDNA clearance had significantly worse DFS than those with sustained clearance (HR = 5.27, 95% CI: 2.49–11.14, p<0.0001). Among MRD- pts, ACT conferred no significant DFS benefit vs observation (HR=1.52, p<0.05). Among MRD+ pts, ACT did not reach statistical significance. ctDNA positivity predicted recurrence with a lead time up to 23.9 mo (median 3.8 mo) before imaging, including in low ctDNA shedding sites. 7% had metastatic disease diagnosed earlier because of a positive test, prompting timely therapy. ctDNA testing was associated with higher than historical rates of oligometastasis-directed therapy (17%). **Conclusions:** Our results highlight the value of post-surgical ctDNA monitoring as a prognostic biomarker in CRC and its potential value for treatment decision making. Clinical utility of ctDNA-guided AC will further be established by ongoing trials (CIRCULATE-NA). Research Sponsor: None.

Safety, immunogenicity, and efficacy of Ad5.F35-GUCY2C-PADRE vaccine in patients with GI cancers at high risk of relapse: Results from a phase 2A trial. First Author: Babar Bashir, Sidney Kimmel Comprehensive Cancer Center at Thomas Jefferson University Hospital, Philadelphia, PA

Background: Guanylyl cyclase C (GUCY2C) is an intestinal tumor antigen ectopically expressed in some gastroesophageal and pancreatic cancers, highly expressed in nearly all colorectal cancers (CRC), and retained in metastases. Adenovirus serotype 5 (Ad5)-based cancer vaccines, including those targeting GUCY2C, are limited by pre-existing neutralizing antibodies (NAbs) targeting Ad5. Ad5.F35-GUCY2C-PADRE is a chimeric Ad5 vector (fiber of serotype 35) developed to overcome anti-Ad5 immunity and induce durable antitumor T-cell responses. We report initial immunogenicity, safety, and recurrence outcomes from a phase 2A dose-finding study in patients with resected GI malignancies. **Methods:** This open-label phase 2A study enrolled patients with resected, high-risk GI adenocarcinomas (CRC, pancreatic, gastric, and small bowel) with no evidence of disease 4-24 wks after standard adjuvant therapies. Oligometastatic stage IV CRC patients were also allowed (n=8). Patients were randomized to receive three i.m. administrations of Ad5.F35-GUCY2C-PADRE at 1×10^{11}, 1×10^{12}, or 5×10^{12} viral particles (vp) at 4-wk intervals. Primary endpoints were safety and GUCY2C-specific T-cell responses (IFNγ ELISpot). Exploratory endpoints included the impact of NAbs on T-cell responses and RFS, and the impact of dose on immunological and clinical outcomes. **Results:** Forty-six patients (29 CRC) completed treatment and were evaluable. Vaccination was well tolerated with no DLTs or TRSAEs; AEs were predominantly grade 1-2 flu-like symptoms. GUCY2C-specific T-cell responses increased in frequency and magnitude in a dose-dependent manner. Nearly all patients receiving higher doses produced T-cell responses regardless of NAb status (Table), supporting Ad5.F35 overcoming pre-existing NAbs. At the 2-year follow-up, there was a dose-dependent improvement in RFS among stage II-III CRC patients (Table), and RFS was significantly improved among immune responders vs non-responders ($P < 0.05$). **Conclusions:** Ad5.F35-GUCY2C-PADRE is safe, overcomes pre-existing Ad5 immunity, and induces robust, dose-dependent GUCY2C-specific T-cell responses. Vaccine-induced immunity is associated with improved RFS in CRC, supporting further development of the off-the-shelf Ad5.F35 platform for cancer vaccines and Ad5.F35-GUCY2C-PADRE for CRC recurrence prevention. Clinical trial information: NCT04111172. Research Sponsor: Targeted Diagnostics and Therapeutics, Inc.

SOCCER: A randomized phase II trial comparing complete clinical response after short course radiation or chemoradiation and consolidation chemotherapy in rectal cancer. First Author: Ramakrishnan Ayloor Seshadri, Integrated Cancer Care Group, Chennai, India

Background: The preferred total neoadjuvant treatment (TNT) regimen for an intentional watch-and-wait (W&W) approach in patients with rectal cancer is long course chemoradiation (LCRT) and consolidation chemotherapy (CNCT). The role of short course radiation (SCRT) and CNCT in this context is not well defined. The shorter treatment time of SCRT has advantages, especially in resource-constrained settings. This study aimed to select the more promising of the two TNT strategies for a W&W approach in patients with rectal cancer for further phase III evaluation. **Methods:** This dual-center, randomized phase II trial was conducted in Chennai and Vellore, India. Patients with rectal adenocarcinoma within 8cm of the anal verge, T3N0 or T1-3N+ on magnetic resonance imaging (MRI) who required neoadjuvant radiation and surgery, were randomized to one of two arms: Arm A - LCRT (54Gy with capecitabine) + 6 cycles of CAPOX (capecitabine + oxaliplatin), Arm B - SCRT (25Gy) + 6 cycles of CAPOX. Tumor response was assessed at 24 weeks from completion of radiation by digital rectal examination, sigmoidoscopy and MRI and categorized by a pre-defined criterion. Primary endpoint was cCR or near cCR. Patients with a cCR at first assessment or at a second assessment 12 weeks after a near cCR were offered W&W. Based on Simon's randomized phase II pick-the-winner design, 40 patients were required to achieve a 90% probability of correct selection, assuming a 50% cCR and a 20% absolute difference, without formal superiority testing. Secondary endpoints included adverse events, treatment compliance, post-operative complications, 2-year organ preservation, local regrowth, disease-free survival, diagnostic performance of response assessment criteria, and quality of life. **Results:** Among 46 patients randomized between 2022 and 2025, primary endpoint was assessed in 43 (modified intention-to-treat population). Median age (range), proportion of T3, node positive tumors and mesorectal fascia involvement were 54 years (27-69), 86.3%, 54.5%, 63.6% and 49 years (31-68), 86.9%, 56.5%, 60.8% in Arm A and B, respectively. For primary and short-term secondary endpoints, see Table. **Conclusions:** SCRT + CNCT was superior to LCRT + CNCT in inducing cCR/near cCR in patients with rectal cancer and emerged as the preferred regimen for further evaluation of an intentional W&W approach in a phase III study. Clinical trial information: CTRI: 2021/01/030370. Research Sponsor: None.

End-point	Arm A	Arm B
No. of complete + near complete clinical response	8/20 (40%)	17/23 (73.9%)
Adverse events ≥Grade 3		
During Radiation	2 (in 20 patients)	1 (in 23 patients)

Prediction of localized rectal cancer outcomes with ctDNA analysis using a novel ultrasensitive structural variant (SV)-based method. First Author: Cecilia Merk, Karolinska Institutet, Stockholm, Sweden

Background: Rectal cancer has a high risk of recurrence and incidence is rising. Treatment for rectal cancer has moved towards individualization and organ sparing approaches. Selection for treatment is based on radiology, CEA and pathological risk factors, but stronger biomarkers are needed to improve outcomes. Circulating tumor DNA (ctDNA) has shown high prognostic impact on outcome in localized colorectal cancer (CRC), but few patients with rectal cancer have been included in these trials. In this study, we aim to investigate the role of ctDNA in predicting rectal cancer outcomes. **Methods:** The multicenter CITCCA study included patients with stage I-III CRC planned for curative treatment and investigated prospective, longitudinal ctDNA testing. Neoadjuvant (NAT) and/or adjuvant (ACT) treatment was administered according to local guidelines. All patients underwent surgery. Follow-up was according to Swedish standard-of-care with CT and CEA at 1 and 3 years. Patients were recruited in Sweden, 2020–2024. Sampling of ctDNA occurred before and after surgery at 4-6 weeks, 3 and 6 months,1 and 2 years and was analysed with Pathlight, an ultrasensitive SV-based assay. The primary outcome was recurrence-free interval (RFI). **Results:** The study included patients with rectal cancer with a median age of 67 years (range 31-81). Ninety-four patients (65%) received upfront surgery and 51 patients (35%) NAT, of which 36 patients (71%) received short-course radiotherapy and 15 (29%) had total neoadjuvant treatment. Fifty-two patients (36%) were (y)pTNM stage I, 45 patients (31%) stage II and 48 patients (33%) stage III. ACT was given to 38 patients (26%). The success rate for assay generation was 96%. At a median follow-up of 35 months (range 2-46), 23 patients recurred or died of rectal cancer. Before surgery, ctDNA was detected in 136 patients (94%). Notably, 92% (55/60) of patients had ctDNA detected prior to surgery, despite NAT. All patients who recurred had positive ctDNA before surgery, regardless of NAT. Postoperatively, at the 4-6 week clinical landmark (CLM), 18 patients (16%) had detectable ctDNA. At the first test after treatment termination, 17 patients (15%) were ctDNA positive and ctDNA detected recurrence ahead of radiology in 13 patients, including 4/4 patients with stage I disease. Positive ctDNA was strongly associated with recurrence (HR: 94; 95% CI: 20-440) and 3-year RFI at CLM was 22% (95% CI: 9%-56%) for ctDNA positive and 95% (95% CI: 90%-100%) for ctDNA negative patients. **Conclusions:** CtDNA has strong prognostic potential in stage I-III rectal cancer. Using an ultrasensitive SV-based method shows great promise for individualization of treatment in rectal cancer and should be investigated prospectively for organ-sparing selection. Clinical trial information: NCT04726800. Research Sponsor: Cancerfonden.

Neoadjuvant treatment of QL1706 in patients with resectable microsatellite instability-high/mismatch repair-deficient colon cancer: Results from a phase 1b trial. First Author: Zi-Xian Wang, State Key Laboratory of Oncology in South China, Guangdong Provincial Clinical Research Center for Cancer, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Immune checkpoint inhibitors in neoadjuvant setting have brought clinical benefits for patients with various tumors. This study aimed to evaluate the efficacy and safety of iparomlimab and tuvonralimab (QL1706), a bifunctional antibody targeting both PD-1 and CTLA-4, as neoadjuvant treatment in patients with microsatellite instability-high (MSI-H)/mismatch repair-deficient (dMMR) colon cancer. **Methods:** In this single-arm phase 1b trial, previously untreated patients with resectable stage IIb-III MSI-H/dMMR colon cancer were recruited. Patients were administered neoadjuvant treatment of QL1706 at 5 mg/kg via intravenous infusion every three weeks for four cycles. Radical resection was scheduled between 4 and 6 weeks after last dose of neoadjuvant treatment. The primary endpoint was pathological complete response (pCR) rate. The efficacy analysis set included patients who were confirmed dMMR/MSI-H, received at least one dose of treatment, and had post-surgery pathological results. The safety analysis set included patients who received at least one dose of treatment. **Results:** As of data cut-off date on Oct 15, 2025, 43 patients were enrolled (median age: 56.0 years; males: 58.1%; ECOG PS 1: 55.8%; Lynch syndrome: 34.9%). Scheduled radical resection were performed in 34 patients. A total of 34 patients were included in the efficacy analysis set. The pCR rate was 88.2% (30/34, 95% confidence interval [CI]: 72.5%-96.7%). The major pathologic response rate was 91.2% (31/34, 95% CI: 76.3%-98.1%). In high-risk patients (T4 or N2), the pCR rate was 86.4% (19/22, 95% CI: 65.1%-97.1%). All patients (100%) received surgery had R0 resection. Median treatment exposure was 2.1 months (range, 0.0-3.9). Treatment-emergent adverse events (TEAEs) of grade ≥3 occurred in 12 patients (27.9%); two (4.7%) patients were treatment-related. Immune-related adverse events grade ≥3 occurred in two (4.7%) patients, including one grade 3 acute kidney injury and one grade 4 hypersensitivity, both of which recovered finally. Treatment-related serious adverse events occurred in three (7.0%) patients. No patient cancelled or delayed the surgery due to TEAE. No TEAE leading to death occurred. The incidence of grade ≥3 TEAE during the surgery phase was 11.8% (4/34). **Conclusions:** Neoadjuvant treatment of QL1706 showed promising pCR rate and manageable safety in patients with MSI-H/dMMR colon cancer. A phase 3 trial is ongoing to further confirm the efficacy and safety of QL1706 as neoadjuvant treatment in patients with resectable MSI-H/dMMR colon cancer. Clinical trial information: NCT06686576. Phase II trial of anti-PD-1 monoclonal antibody and FOLFOXIRI combined with long-course radiotherapy as the total neoadjuvant treatment for proficient, mismatch repair, locally advanced low rectal cancer (PANFORTE). First Author: Jianhong Peng, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University, Guangzhou, China

Background: The current standard treatment for locally advanced low rectal cancer (LALRC) achieves a complete response (CR) rate of only 20–30%. Consequently, radical surgery frequently results in the loss of anal organs, severely affecting patients' quality of life. Therefore, there is an urgent clinical need to identify novel strategies that can maximize tumor regression and preserve anal function. Recent trials have demonstrated radiotherapy showed a distinctive synergistic anti-tumor effect with immune checkpoint inhibitors. Therefore, this study aims to assess the efficacy and safety of an immunotherapy-based total neoadjuvant therapy (TNT) in patients with proficient mismatch repair (pMMR) LALRC. **Methods:** Eligible patients (pts) on this investigator-initiated phase II study had pMMR LALRC with ECOG performance status ≤ 1 and an inferior tumor margin distance from the anal verge (DAV) ≤ 5 cm. Eligible patients receive 4 cycles of FOLFOXIRI plus serplulimab (200 mg). Subsequently, they undergo long-course radiotherapy combination with capecitabine and 2 cycles of serplulimab (200 mg), followed by another 4 cycles of FOLFOXIRI and serplulimab (200 mg). The primary endpoint is CR rate with the sum of clinical complete response (cCR) and pathological complete response (pCR). Secondary endpoints include sphincter preservation rate and safety. **Results:** Between November 2023 and April 2025, 53 patients were enrolled with male percentage 62.3%, median age of 55 years (Range, 28–72) and median DAV of 3 cm (Range, 0.4–5.0). 92.5% (49/53) of patients completed the full TNT regimen. Among the 51 patients eligible for endpoint assessments, the overall CR rate was 68.6% (35/51), and the sphincter preservation rate was 94.1% (48/51). 31 (60.8%) patients achieving cCR opted for a watch-and-wait approach, whereas 20 patients underwent surgery. 20% (4/20) achieved pCR and 70% (17/20) had a tumor regression grade (TRG) of 2. The most common AEs was neutropenia (grade 3-4, 66.0% [35/53]). Other grade 3-4 AEs included leukopenia (32.1%, 17/53), lymphopenia (20.8%, 11/53), and thrombocytopenia (18.9%, 10/53). Immune-related 3-4 AEs comprised myocarditis (1.9%,1/53) and elevated transaminases (1.9%,1/53). **Conclusions:** Our study indicates that this TNT regimen significantly enhances CR rates and anal preservation in pMMR LALRC compared to historical benchmarks, with an acceptable safety profile. These findings suggest that this new approach may be an alternative treatment option for LALRC patients who strongly desire anal preservation. Clinical trial information: NCT06099951. Research Sponsor: None.

The role of adjuvant chemotherapy in high-risk stage II colon cancer with microsatellite instability-high or DNA mismatch repair deficiencies: A multicenter pooled analysis (KCSG-CO24-03). First Author: Joon Young Hur, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Background: The benefit of adjuvant chemotherapy (CTx) for high-risk stage II MSI-H/dMMR colon cancer remains controversial, with discordant international guidelines. This study evaluated clinical outcomes comparing adjuvant CTx vs. observation in this population. **Methods:** This multicenter retrospective analysis included 192 patients with high-risk stage II MSI-H/dMMR colon cancer who underwent curative resection (2010-2020). High-risk features included pT4, grade 3-4, lymphovascular invasion, bowel obstruction/perforation, perineural invasion (PNI), inadequate lymph node sampling (<12), or close margins. Primary endpoint was 5-year relapse-free survival (RFS). Secondary endpoints included 5-year overall survival (OS). A propensity score-matched (PSM) analysis was performed. **Results:** Of 192 patients, 128 (66.6%) received adjuvant CTx (FOLFOX n=66, capecitabine n=40, FL n=17, others n=5) and 64 (33.3%) underwent observation. Median follow-up was 60.5 months. During follow-up, 24 RFS events and 15 OS events occurred. The 5-year RFS was significantly higher with adjuvant CTx versus observation (94.0% vs. 83.7%; P=.001), as was 5-year OS (98.3% vs. 89.0%; P=.001). Multivariate analysis confirmed adjuvant CTx as an independent prognostic factor for both RFS (HR 0.278, 95%CI 0.117-0.660; P=.003) and OS (HR 0.176, 95%CI 0.052-0.594; P=.005). PNI independently predicted worse RFS (HR 4.053; P=.002) and OS (HR 7.490; P=.001). Subgroup analysis demonstrated pronounced benefit in pT4 patients (OS HR 0.094, P=.031; RFS HR 0.230, P=.038) and significant benefit in T3 patients (RFS HR 0.326, P=.031). No survival differences were observed between oxaliplatin-containing vs. non-oxaliplatin regimens (5-year RFS P=.636; OS P=.757). PSM analysis (n=56 pairs) confirmed the survival benefit (matched OS HR 0.344, P=.036). **Conclusions:** Adjuvant CTx significantly improves RFS and OS in high-risk stage II MSI-H/dMMR colon cancer, particularly in pT4 and PNI patients. The absence of regimen-specific survival differences suggests that treatment administration itself, rather than specific agents, determines outcomes. These findings provide evidence to bridge NCCN and ESMO guideline discrepancies, supporting risk-stratified adjuvant CTx in this population. Research Sponsor: None.

Stage-specific circulating tumor DNA (ctDNA) positivity and minimal residual disease (MRD) decision making in colorectal cancer (CRC) in the prospective INTERCEPT program. First Author: Emerik Osterlund, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: ctDNA positivity is a strong prognostic biomarker for recurrence after curative-intent procedures for CRC and defines MRD in the absence of radiographic disease. Our aim was to assess stage-specific positivity rates across follow-up intervals and the clinical actions associated with ctDNA+. **Methods:** The INTERCEPT program enrolled patients undergoing curatively intended procedures for stage I-IV CRC at MD Anderson Cancer Center. Tumor informed MRD assays (Signatera) were drawn postoperatively and every 3 months according to reimbursement guidelines. ctDNA draws were grouped into 6-month intervals from completion of definitive therapy. Clinical decisions after the first ctDNA+ result in the MRD window were classified as: MRD-trial, systemic therapy, diagnostic escalation, early follow-up, ctDNA confirmation, or no change. **Results:** The final cohort included 1,603 patients (40% stage IV, 32% stage III, 20% stage II, 8% stage I). Median follow-up was 18.4 months. Patients that were ctDNA- on first post-definitive draw had longer recurrence-free survival (RFS) than ctDNA+ patients (median RFS 62.6 vs 4.8 months, HR 11.6 [95% CI 9.6-14.1]), remaining significant in stage subgroups. Among all patients 28% were ctDNA+ at any post-definitive timepoint, the rates were highest for stage IV, followed by stage III, II, and I (Table). ctDNA+ rates were highest in early follow-up and got lower at later intervals (21% to 5%), with similar patterns for all stages. Among 271 patients that were ctDNA+ in the MRD window the initial therapeutic approach was MRD trial screening for 59 (22%), diagnostic escalation in 73 (18%), early follow-up in 57 (21%), confirmation of ctDNA+ by repeat testing in 23 (8%), no change in management for 38 (14%), and 21 (8%) patients started other systemic therapy. MRD trials were discussed prior to recurrence with 144 (53%) of the patients. **Conclusions:** ctDNA positivity is more common in higher stage tumors and becomes less frequent during follow-up. ctDNA positivity confirms its established prognostic value and meaningfully impacts clinical management, including diagnostic workup and MRD trial enrollment. Even within a single center, heterogeneity in initial management of ctDNA+ patients and timing for MRD trial enrollment is evident. Research Sponsor: None.

Stage-specific ctDNA+ rates during follow-up after definitive therapy.

	All	Stage IV	Stage III	Stage II	Stage I	p
Any time	444 / 1,603 (28%)	313 / 646 (48%)	87 / 513 (17%)	40 / 322 (12%)	4 / 122 (3%)	<0.001

Efficacy of probiotics combined with glutamine compound for acute radiation enteritis during neoadjuvant chemoradiotherapy in locally advanced rectal cancer: A randomized controlled trial (NCT05406882). First Author: Qiaoli Wang, Department of Radiation Oncology/Abdominal Oncology, Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: Acute radiation enteritis (ARE) occurs in up to 80% of patients undergoing abdominal-pelvic radiotherapy, with severe ARE causing treatment interruption in 20%. Current prophylactic strategies remain inadequate. Small-sample studies suggest probiotics and glutamine may reduce radiation-induced mucosal injury and intestinal syndrome (e.g., diarrhea), but evidence-based validation is insufficient. This study investigated the efficacy of probiotics combined with glutamine compound preparation in preventing and alleviating ARE in locally advanced rectal cancer (LARC) patients receiving chemoradiotherapy. **Methods:** This prospective randomized trial enrolled 176 stage II-III rectal adenocarcinoma patients receiving preoperative chemoradiotherapy, randomized 1:1 to prophylactic (group A, n=86) versus therapeutic (group B, n=84) (treatment started when patients had ≥ 2° ARE) administration of probiotics combined with glutamine compound. Concurrent chemoradiotherapy consisted of pelvic radiation 50-50.4 Gy/25-28 fractions plus oxaliplatin/capecitabine. Weekly assessments documented ARE (including anal tenesmus/pain, diarrhea, constipation, hematochezia) basing on RTOG and CTCAE v5.0 criteria. Primary endpoints: incidence of grade ≥2 ARE and diarrhea. Chi-square or Fisher's exact tests were used for analysis through R version 4.4.2. $P<0.05$ indicated statistical significance. **Results:** The enrollment was completed on August 5, 2025. Six patients withdrew consent (group A: 1; group B: 5). Ultimately, there were 170 patients who completed concurrent chemoradiotherapy (84 control, 86 treatment), including 105 males (61.8%). The incidence rate of ≥ 2° ARE in group A was significantly lower than that in group B (44.2% vs 73.8%, $P<0.001$; RR=0.60, 95%CI: 0.46-0.78). The incidence rate of ≥ 2° diarrhea was also significantly lower in group A (34.9% vs 54.8%, P=0.01). There was 1.2% (1/86) and 3.6% (3/84) of grade 3 ARE in the two groups, respectively; and all these four patients experienced grade 3 diarrhea. The incidence rate of ≥ 2° ARE increased with higher doses of pelvic radiotherapy in both groups, with the peak incidence occurring in the fifth week (24.1%) of group A and the fourth week (35.7%) of group B, respectively. **Conclusions:** Prophylactic probiotics combined with glutamine compound has a preventive effect of severe radiation enteritis and diarrhea during concurrent chemoradiotherapy for rectal cancer. Clinical trial information: NCT05406882. Circulating tumor DNA clearance of adjuvant chemotherapy in localized colorectal cancer using an ultrasensitive structural variant–based assay. First Author: Cecilia Merk, Karolinska Institutet, Stockholm, Sweden

Background: High-risk localized colorectal cancer (CRC) remains prognostically unfavorable. Adjuvant chemotherapy (ACT) is administered to patients with poor-risk features to eradicate molecular residual disease (MRD) and improve outcome. Despite ACT selection, some patients experience recurrence and others receive unnecessary treatment. Circulating tumor DNA (ctDNA) has emerged as a strong prognostic biomarker that could improve selection for ACT, but detection in the MRD setting is dependent on high sensitivity. In this study, we use an ultrasensitive assay to investigate ACT clearance in localized CRC patients included in the CITCCA trial and its impact on outcome. **Methods:** Patients with stage I–III CRC were enrolled in a prospective Swedish cohort study between 2020-2024. Standard of care treatment was given, and patients were followed with longitudinal ctDNA before and after surgery at 4-6 weeks, 3 and 6 months, 1 and 2 years. The clinical landmark (CLM) was defined as the 4-6 week postoperative test prior to initiation of ACT. The first sample after definitive treatment (FDT) was defined as the first test after treatment termination. ACT clearance was defined as a positive ctDNA test at either CLM or at CLM and 3 months, with subsequent negative ctDNA, in patients without recurrence. An ultrasensitive SV-based assay, Pathlight, was used for ctDNA analysis. The primary outcome was recurrence-free interval (RFI). **Results:** Of the 377 patients included, 135 patients (36%) received ACT with a median length of 5.2 months (range 0.1-7.4). Single agent fluoropyrimidine was given to 65 patients (48%) and 70 (52%) received an oxaliplatin-based doublet. Analyzable CLM samples were obtained from 106 patients (79%). Nineteen patients (18%) were ctDNA positive at CLM and received ACT. ctDNA positive patients who received ACT still showed a substantially higher risk of recurrence compared to ctDNA negative patients (HR, 38; 95% CI, 15–97). The same was seen in ctDNA-positive patients who did not receive ACT, i.e. clinically low-risk (HR, 35; 95% CI, 14–88). In the ctDNA positive cohort, patients who received ACT versus no ACT had a 2-year RFI of 58% (95% CI:39%-85%) versus 39% (95% CI:22%-69%). Persistent ACT clearance was seen in 8 patients, none of whom recurred. Transient clearance was seen in 6 patients, all of whom recurred. Five patients had persistently positive ctDNA despite ACT; all recurred. Eighty-seven patients (82%) were ctDNA negative at CLM but received ACT; 9 of these recurred (10%). Eighteen patients were ctDNA positive at CLM but did not receive ACT and 13 of these recurred. **Conclusions:** ctDNA is a strong prognostic biomarker and may be utilized to guide adjuvant treatment decisions in patients with localized CRC. Permanent clearance of ctDNA by administration of ACT is a favorable prognostic feature whereas ctDNA persistence after ACT predicts recurrence. Clinical trial information: NCT04726800. Research Sponsor: Cancerfonden.

Health-related quality of life (HRQOL) in the phase 3 trial of standard chemotherapy alone or combined with atezolizumab as adjuvant therapy for patients with stage III deficient DNA mismatch repair (dMMR) colon cancer (Alliance A021502, ATOMIC). First Author: Amylou C. Dueck, Alliance Statistics and Data Management Center, Mayo Clinic Arizona, Scottsdale, AZ

Background: For patients (pts) with dMMR stage III colon cancer, the addition of atezolizumab (atezo) to adjuvant 5-fluorouracil, leucovorin plus oxaliplatin (mFOLFOX6) significantly improved disease-free survival in ATOMIC (NCT02912559). Here we present HRQOL data. **Methods:** Pts with surgically resected stage III dMMR colon cancer were randomized (1:1) to receive mFOLFOX6 + atezo (840 mg IV q2 weeks) for 12 cycles (6 months [mo]) followed by atezo monotherapy for 13 cycles (12 mo total) versus mFOLFOX6 for 12 cycles. HRQOL was an exploratory endpoint measured using the FACT-C (includes FACT-G), FACT/GOG-NTX, EQ5D-5L, and PRO-CTCAE. Optional participation was by paper surveys at trial registration, prior to treatment cycles 4 and 7, and at 6, 12, and 36 mo after registration. Mean changes from baseline (BL) were compared between treatment arms using general linear mixed models (negative mean changes indicate worsening). At 6 mo, a two-sided 95% confidence interval excluding a difference of 1.9 points (FACT/GOG-NTX) and 6 points (FACT-C Trial Outcome Index [TOI]) favoring the mFOLFOX6 arm would indicate non-inferiority of the addition of atezo. Rates of side effect bother (FACT-G item GP5) and pt-reported adverse events (AEs) by PRO-CTCAE (composite scores, baseline adjusted) were compared using Fisher's exact tests. **Results:** Of 712 randomized pts, 581 (285 atezo+mFOLFOX6; 296 mFOLFOX6) consented to participate in the survey. Pts completed 2398/3021 (79%) of expected surveys across all time points (1218/1489 [82%] atezo+mFOLFOX6; 1180/1532 [77%] mFOLFOX6). The difference in mean changes from BL between arms indicated non-inferiority of the addition of atezo at 6 mo (table); differences remained small at 12 and 36 mo. No significant differences in mean changes from BL between arms were found at 6, 12, or 36 mo for any scale. At 6 mo, 16% vs 20% of pts in each arm reported at least "quite a bit" of side effect bother (p=0.34), favoring atezo. Across cycles, atezo was associated with higher rates of pt-reported itchy skin (62% vs 48%), cough (53% vs 43%), and shortness of breath (51% vs 41%) [all $p<0.05$]. **Conclusions:** Addition of atezo to mFOLFOX6 slightly increases pt-reported AEs, but its effect on HRQOL is minimal and not clinically meaningful. Results support tolerability of atezo+mFOLFOX6 as standard of care adjuvant treatment for pts with dMMR stage III colon cancer. Neoadjuvant chemotherapy followed by transanal endoscopic surgery (TES) and selective chemoradiation or total mesorectal excision (TME) for early-stage rectal cancer: The Ottawa Hospital experience. First Author: Mohammed Al Darai, Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada

Background: Organ-sparing therapy for early-stage rectal cancer may avoid permanent ostomy or functional disturbances commonly known as low anterior resection syndrome (LARS). TES is increasingly used for treatment of selected T1N0 or T2N0 rectal cancer. The CCTG CO.28 (NEO) phase II trial evaluated neoadjuvant chemotherapy then TES surgery for early-stage rectal cancer (Kennecke et al, JCO 2023). On the CO.28 trial, patients (pts) with post-chemotherapy ypT3N0 tumours were to have neoadjuvant chemoradiation (CRT) then TME. Pts with ypT2 or poor risk ypT1 tumours were to have TME. However, several pts insisted on organ sparing alternatives such as adjuvant CRT or active surveillance. Our approach evolved from CO.28 by incorporating more selective adjuvant CRT instead of routinely resorting to TME. **Methods:** This retrospective study conducted at the Ottawa Hospital evaluated the outcomes of pts with early rectal cancer treated with the NEO approach and selective adjuvant CRT. The primary outcome was 3-yr TME free survival. Secondary outcomes included safety, 3-yr disease-free survival (DFS), 3-yr permanent colostomy free survival, 5-yr overall survival (OS), pathological complete response rate (pCR), proportion of pts requiring CRT and proportion of pts with LARS at 2 yrs. **Results:** N = 50 pts received a NEO approach and selective adjuvant chemoradiation. N = 19 were part of the previously reported CO.28 trial and N = 31 were a consecutive cohort treated off protocol. Median age was 63 (42-83) yrs, 58% were male. Rectal location was low/mid/upper in 34%/56%/10%. Baseline T stage was T2 (76%) and T3 (10%). Neoadjuvant CAPOX (64%) or FOLFOX (36%) was completed by 88% of pts and Gr 3 AEs occurred in 31%. At TES, pCR was achieved in 32% of pts. CRT was received by 33% of pts. Median follow-up was 30.2 (2.6-86.4) months. LARS was present at 2 yr in 15%. 3-yr TME-free survival was 82% (95% C.I. 69 to 94%). 3-yr permanent colostomy-free survival was 88% (95% C.I. 78 to 99%). 3-yr DFS after all local therapy was 98% (95% C.I. 93 to 99%). One pt developed both local plus distant recurrence. 5-yr OS was 95% (95% C.I. 85 to 99%). One pt who was disease free on surveillance died of an unrelated COPD exacerbation. **Conclusions:** The NEO approach of neoadjuvant chemotherapy then TES combined with selective adjuvant CRT demonstrated promising organ-preservation outcomes in early-stage rectal cancer, achieving high TME-free survival. This strategy offers a meaningful alternative to routine TME, potentially reducing the risk of permanent ostomy and LARS. Research Sponsor: None.

Impact of postsurgical circulating tumor DNA (ctDNA) dynamics on eligibility of colorectal cancer (CRC) patients for randomized ALTAIR trial: Implications for treat-on-molecular-recurrence (TOMR) trials. First Author: Hideaki Bando, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: Postsurgical ctDNA positivity is strongly associated with recurrence risk and is driving the development of TOMR trials like the phase III ALTAIR trial (NCT04457297), which evaluated the benefit of trifluridine/tipiracil versus placebo in CRC patients (pts) with ctDNA positivity in the absence of clinical relapse. We evaluated the impact of longitudinal ctDNA dynamics during adjuvant chemotherapy (ACT) and surveillance on eligibility for enrollment into ALTAIR. **Methods:** CIRCULATE-Japan's GALAXY (UMIN000039205) study screened clinical stage II-IV CRC pts receiving standard-of-care (SOC) perioperative chemotherapy for eligibility for interventional trials by ctDNA monitoring using the personalized, tumor-informed Signatera assay in plasma collected at 1, 3, 6, 9, 12, 18, and 24 months (mos) post-surgery. Pts with ctDNA positivity without clinical recurrence were eligible for ALTAIR within 3 months of detection. We analyzed ctDNA dynamics and eligibility across all GALAXY sites, extending prior analyses limited to ALTAIR-participating sites. **Results:** Of 5,355 pts enrolled by April 2023, 693 (12.9%) were ctDNA-positive 2–10 weeks post-surgery (MRD-positive). Of 378 MRD-positive pts who received ACT, 117 (31.0%) remained persistently positive, 76.1% of whom did not relapse within 3 mos. ctDNA cleared after ACT in 237 pts, but 122 (51.5%) reconverted to positive, 67.2% of whom remained relapse-free for ≥3 mos after reconversion. Among 1,341 MRD-negative pts receiving ACT, 183 (13.6%) converted to ctDNA-positive, 123 (67.2%) of whom remained relapse-free for ≥3 mos after molecular relapse. Overall, 17.1% of GALAXY pts met ALTAIR ctDNA-based criteria with stage-specific eligibility rates of 13.2% (II), 14.7 % (III), and 34.6 % (IV). Overall, 243 (4.5%) were enrolled in ALTAIR, including 18.6% of MRD-positive and 2.4% of MRD-negative pts. **Conclusions:** Approximately one-third (123/334) of ALTAIR-eligible pts were initially MRD-negative and later converted to ctDNA-positive without early clinical relapse, highlighting the importance of longitudinal ctDNA monitoring in TOMR trial design. When compared to the previous analysis limited to ALTAIR-participating sites, we observed higher eligibility yet lower enrollment rates in the full cohort at all GALAXY sites, underscoring the need for broader access and efficient enrollment networks to optimize TOMR trials. Clinical trial information: NCT04457297. Research Sponsor: Japan Agency for Medical Research and Development; 19ck0106447h0002, 21ck0106711h0001, 21ck0106710h0001, 22lk0201164h0001 and 22lk0201148h0002; National Cancer Center Research and Development Fund; no. 2021-A-6.

ctDNA dynamics	MRD positive (N = 378)	MRD negative (N = 1,341)
Persistently positive, all	117 (31.0%)	NA
Persistently positive, eligible for ALTAIR	89 (23.5%)	NA
Transient clearance, all	122 (32.2%)	NA
Transient clearance, eligible for ALTAIR	82 (21.7%)	NA
Turned positive, All	NA	183 (13.6%)
Turned positive, eligible for ALTAIR	NA	123 (9.2%)

Molecular residual disease (MRD) detection using an ultra-sensitive assay in a prospective colorectal cancer cohort: The VICTORI study. First Author: Joao Paulo Solar Vasconcelos, BC Cancer - Vancouver, University of British Columbia, Vancouver, BC, Canada

Background: Circulating tumor DNA (ctDNA) detection of molecular residual disease (MRD) is prognostic in colorectal cancer (CRC) but missed recurrences highlight constraints in assay performance. VICTORI is a prospective observational study investigating an ultra-sensitive MRD assay (NeXT Personal) in CRC patients undergoing curative treatment. **Methods:** Whole-genome informed panels of ~1,800 variants interrogated plasma collected pre-curative loco-regional treatment, q2 weeks post-surgery (weeks 2–8, landmark window), and subsequently every 3 months (3-36 months, surveillance window). **Results:** 795 plasma samples from 109 patients were analyzed, with median follow-up of 21.1 months and 31 recurrences observed. Cohort characteristics: 61 (56.0%) rectal cancer, 48 (44.0%) colon cancer; 81 (74.3%) stage I-III; 56 (50.5%) had neoadjuvant treatment; 106 (97.2%) had surgery as curative procedure. Pre-surgical sensitivity (treatment-naïve) was 96.0% (n=48/50) and specificity was 100% (no detection in pathologic complete responders; 0/10). Landmark window overall sensitivity for recurrence was 83.9% (n=26/31) with 69.2% (18/26) of detections being <100 ppm. Sensitivity was similar weeks 4–8 (81.5% week 4 [n=22/27]; 82.1% week 6 [23/28]; 85.7% week 8 [24/28]), and lower at week 2 (52.4% [11/21]) when post-surgical cell-free DNA peaked (median 2.80 ng/mL pre-surgery to 9.40 at week 2; $p=8.7\times10^{-12}$). Sampling between weeks 4-8 yielded a sensitivity of 80.0% (n=24/30) at the first available timepoint and 89.7% (26/29) with incorporation of an additional subsequent sample. Detection of ctDNA at any landmark window timepoint was associated with inferior outcomes (adjusted HR [aHR]: 10.28 [95% CI: 4.03-26.23], $p=1.06\text{x}10^{-06}$). Week-4 detection <100 ppm was prognostic and conferred a 6.5 month longer lead time than detections ≥100ppm (HR 4.09, p=0.018). All patients who recurred with surveillance samples had ctDNA detected prior to recurrence (sensitivity: 100% (n=28/28). ctDNA identified 100% of lung- and liver-only metastases; most initial detections were <100 ppm (75% and 71.4%, respectively). In evaluable patients, lead time from ctDNA detection to recurrence was 176 days (including patients with expedited imaging upon receipt of a ctDNA detection result). If a higher threshold for ctDNA was used (≥100 ppm) in the same population, the lead time would be >two months shorter (105 days, p<0.001). All patients without ctDNA detected on surveillance remain disease free (NPV 100% [n=63/63]). **Conclusions:** NeXT Personal demonstrated high accuracy, prognostic value, and early detection at ultrasensitive levels with no loss in specificity. The ideal postoperative landmark time point for MRD testing is at 4-8 weeks. Our results show strong clinical potential for an ultrasensitive MRD assay for landmark MRD and longitudinal surveillance in CRC. Research Sponsor: Personalis, Inc.; BC Cancer Foundation.

Lycopene and survival in patients with stage III colon cancer: Findings from CALGB (Alliance)/SWOG 80702. First Author: Seohyuk Lee, Beth Israel Deaconess Medical Center, Boston, MA

Background: Lycopene, a non-provitamin A carotenoid, has been reported to inhibit colon cancer development; however, its prognostic role after colon cancer diagnosis remains unknown. Given emerging evidence suggesting greater intake of lycopene-containing – particularly, tomato-based – foods may improve colon cancer prognosis, we assessed the association of postdiagnosis lycopene consumption with survival among 1666 patients (pts) with stage III colon cancer. **Methods:** Through an NCI-sponsored multicenter phase III adjuvant chemotherapy trial (CALGB/SWOG 80702; NCT01150045), we examined the consumption of total lycopene (dietary plus supplementation) and dietary lycopene as well as lycopene-containing foods (tomato-based foods plus other lycopene-containing foods) and tomato-based foods via validated food frequency questionnaires (FFQs) collected at 6 weeks after randomization (FFQ1) and again 14-16 months post-randomization (FFQ2). Lycopene-related exposures were calculated as time-varying measurements via cumulative averaging. Primary outcome was disease-free survival (DFS), defined as time from FFQ1 completion to colon cancer recurrence or death from any cause. Secondary outcomes were recurrence-free survival (RFS) and overall survival (OS). We estimated associations of lycopene-related exposures with survival via multivariable Cox proportional hazards regression. **Results:** In our cohort, pts with greater total lycopene intake tended to be slightly younger and of male sex and White race, have more left-sided tumors, and report higher caloric intake and physical activity engagement. Over median follow-up of 6.0 (IQR: 5.0-6.1) years, we observed 466 DFS, 395 RFS, and 300 OS events. Pts in the highest relative to lowest quintiles of total lycopene intake experienced significantly improved DFS (HR: 0.60 [95% CI: 0.44-0.83]; P_{trend}=0.006), RFS (HR: 0.58 [95% CI: 0.41-0.82]; P_{trend}=0.007), and OS (HR: 0.60 [95%CI: 0.40-0.89]; P_{trend}=0.02). Similar findings were observed for dietary lycopene intake. Pts consuming >1 serving/day compared to 1 serving/week of all lycopene-containing foods did not experience significantly improved survival. However, when considering only tomato-based foods, we observed a trend toward improved survival (HR for DFS: 0.61 [95% CI: 0.38-0.96]; P_{trend}=0.12). **Conclusions:** Greater lycopene consumption with or without supplementation was associated with lower risk of colon cancer recurrence and death which may be largely driven by tomato-based foods. Our findings may inform clinical nutrition recommendations for pts with colon cancer, with higher intake of tomato-based foods (>1 serving per day) potentially improving colon cancer survival. Future studies, especially interventional trials, are needed to validate our findings. Support: U10CA180821, U10CA180882, U24CA196171; Pfizer; https://acknowledgments.alliancefound.org. Effect of transanal vs. laparoscopic total mesorectal excision on 5-year overall survival in patients with rectal cancer: The TaLaR trial. First Author: Liang Kang, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China

Background: Transanal total mesorectal excision (taTME) has emerged as a widely adopted surgical approach for rectal cancer. Prior studies have reported favorable short-term outcomes, histopathological quality, and complication profiles for taTME compared with laparoscopic total mesorectal excision (laTME). However, the long-term oncologic effectiveness of taTME remains debated. In our previous work, we demonstrated that 3-year disease-free survival after taTME was noninferior to that after laTME among patients with mid-to-low rectal cancer. Building on these findings, the present study aimed to report the 5-year overall survival (OS) between taTME and laTME. **Methods:** We conducted a phase 3, randomized, open-label, noninferiority trial to compare the survival outcomes of taTME versus laTME in patients with rectal cancer located below the peritoneal reflection. This trial encompassed 16 hospitals across 10 provinces in China, with a total enrollment of 1,115 patients. We set the 3-year disease-free survival (DFS) and 5-year overall survival (OS) as the primary endpoints for analysis. This analysis of the 5-year overall survival was conducted following a predefined modified intention-to-treat principle. This study is registered with ClinicalTrials.gov, number NCT02966483. **Results:** As of June 2025, the overall 5-year overall survival (OS) rate was 83.60%, comprising 86.06% in the transanal TME (taTME) group and 81.24% in the laparoscopic TME (laTME) group. The overall 5-year disease-free survival (DFS) rate was 75.90%, with DFS rates of 77.65% in the taTME group and 74.18% in the laTME group. **Conclusions:** Based on preliminary results from a five-year follow-up, taTME is expected to achieve a five-year overall survival (OS) that is non-inferior to laTME. Our findings will support the routine use of taTME in mid-to-low rectal cancer, particularly in men, obese individuals, and those who have received neoadjuvant therapy. Clinical trial information: NCT02966483. Research Sponsor: Sun Yat-sen University Clinical Research 5010 Program.

5-year survival results between the laTME group and the taTME group.

	laTME	taTME	HR
5-year OS (97.5% CI)	81.24% (77.82%-84.82%)	86.06% (83.04%-89.20%)	0.73 (0.54-1.10)
5-year DFS (95% CI)	74.18% (70.45%-78.10%)	77.65% (74.15%-81.32%)	0.86 (0.68-1.11)

Neoadjuvant (NA) chemoradiotherapy (CTRT) plus avelumab (Ave) in locally advanced rectal cancer (LARC): 4-year outcomes of the phase II AVANA trial and their association with computational pathology. First Author: Giovanni Trovato, Medical Oncology, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli–IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy

Background: The AVANA trial investigated the addition of PD-L1 inhibitor Ave to NA CTRT in LARC. Here, we report long-term survival and explore its association with tumor microenvironment (TME) features assessed through computational pathology. **Methods:** AVANA is a multicenter, single-arm, phase II trial enrolling patients (pts) with LARC defined by at least one high-risk feature (cN+, cT4, or high-risk cT3). Pts received NA CTRT combined with six cycles of Ave, followed by surgery. Primary endpoint was pathological complete response (pCR) rate. Secondary endpoints included progression-free survival (PFS) and overall survival (OS). Multiplex immunofluorescence was performed on baseline biopsies and surgical specimens using CODEX platform (Akoya). A deep-learning pipeline using a spatially constrained convolutional neural network for cell detection and a classifier for cell labeling was applied, allowing identification of eight cell populations: cancer cells, normal epithelial cells, fibroblasts, lymphocytes (lym), neutrophils (neu), macrophages, endothelial (endo) cells and myocytes. Cell infiltrates were dichotomized as high or low using optimal cutpoints derived from maximally selected rank statistics. Cell density maps were generated to identify differences in cellular configurations between baseline and surgical specimens. **Results:** The primary endpoint was met, with a pCR of 21.8% (22/101 pts). At a median follow-up of 51.8 months, 26 of 101 pts had a progression event and the 48-month PFS rate was 74.7% (95% CI: 65.0–82.2). Thirteen deaths occurred, yielding a 48-month OS rate of 87.6% (95% CI: 79.1–92.7). Age ($\geq$70 vs $<$70; p=0.371), sex (p=0.897), ECOG PS (0 vs 1; p=0.899), cN positivity (p=0.716), cT stage (1-2 vs 3-4; p=0.264), or mismatch repair status (dMMR vs pMMR; p=0.274) were not associated to PFS. Digital whole-slide images of diagnostic biopsies and surgical specimens were available for 87/101 pts (86.1%). In post-treatment surgical specimens, high neu (p=0.00025) and high lym infiltrate (p=0.0038) correlated with better PFS, whereas high endo cell infiltrate was associated to shorter PFS ($p<0.0001$). Comparisons between baseline and post CTRT+Ave tissues showed that increased endo cell density in surgical specimen relative to baseline biopsies had worse PFS (p=0.0070), while increased neu to cancer cell ratios [HR 0.50 (95% CI: 0.21-1.18); p=0.108] and increased neu density [HR 0.22 (95% CI: 0.03-1.65; p=0.106] showed trends toward better PFS, although not statistically significant. **Conclusions:** AVANA demonstrates the feasibility and activity of adding ICIs to standard CTRT in LARC. Computational pathology analyses suggest that dynamic changes in TME cellular composition could be associated with long-term outcomes, supporting its potential role for pts stratification. Clinical trial information: NCT03854799. Research Sponsor: Merck; GONO Foundation; AIRC.

Clinical outcomes in curatively resected dMMR/MSI-H colon cancer: A retrospective analysis of a multicentric cohort. First Author: Sofie De Meulder, Gastroenterology Department AZ Delta, Roeselare, Belgium

Background: Deficient mismatch repair (dMMR) colon cancer accounts for approximately 15% of localised cases and, despite favourable long-term survival after curative resection, disease recurrence remains a key concern. Recent trials reported a 3-year disease-free survival (DFS) of about 80% after primary surgery with or without adjuvant chemotherapy. In the NICHE-2 trial (Chalabi *et. al,* NEJM 2024), with the addition of nivolumab plus ipilimumab in the neoadjuvant setting, no relapses were observed at three years. The same immunotherapy doublet provides a 3-year overall survival rate of 81% in the metastatic setting (Lonardi *et. al*, ESMO 2025). **Methods:** We conducted a retrospective multicentric cohort study including patients with non-metastatic dMMR/MSI-H colon cancer who underwent resection at 3 Belgian hospitals between January 1, 2013 and December 31, 2020. Patients with synchronous metastases, microsatellite stable (MSS) tumours or insufficient follow-up data ($<$3 years of imaging surveillance) were excluded. Clinical characteristics, adjuvant therapy, relapse incidence and survival outcomes were analysed. **Results:** A total of 219 patients with curatively resected dMMR/MSI-H colon cancer were included. Median age was 74 years (range 24–95). Of the total cohort, stage I accounted for 18.3%, stage II for 58.9% and stage III for 22.8%. Adjuvant chemotherapy was administered in 67 patients (30.7%). Relapse occurred in 11 patients (5.0%), comprising 4 patients with stage II disease and 7 patients with stage III disease. The 3-year DFS was 96.2% (95% CI: 96.1-96.3%). Of those relapsing, 7 received subsequent immunotherapy, yet 3 of those ultimately succumbed to the disease. The 5-year disease-specific mortality was 1.99% (95% CI: 1.96-2.03%), while the 5-year overall mortality was 10.3% (95% CI: 9.89-10.81%). Based on the NICHE-2 benchmark, preventing all 3-year recurrences and disease-specific deaths in this cohort would require treating approximately 26 patients with neoadjuvant nivolumab plus ipilimumab to avert one recurrence, and about 73 patients to prevent one cancer-specific death. **Conclusions:** In this multicentric Belgian cohort of curatively resected dMMR/MSI-H colon cancer, recurrence rates were lower than those observed in the FoXTROT trial (Morton *et. al,* JCO 2023), even when accounting for the slightly higher proportion of stage I disease in our cohort. Most patients, however, died from other non-related causes, reflecting the well-known enrichment of MSI-H colon cancer in elderly women. A trade-off between neoadjuvant nivolumab plus ipilimumab versus primary surgery and salvage treatment with the same regimen should be discussed based on the high numbers needed to treat to avoid one recurrence and the non-trivial immunotherapy related toxicity (de La Fouchardiere *et. al*, Annals of Oncology 2024). Research Sponsor: Kom op Tegen Kanker.

Neoadjuvant immunotherapy combined with radiochemotherapy vs chemotherapy alone in pMMR colon cancers: The TORCH-C randomized phase 2 clinical trial. First Author: Hui Zhang, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: The prognosis for locally advanced colon cancer (LACC) with bulky nodal disease and/or clinically T4 stage remains poor, with high rates of recurrence and metastasis. Immunotherapy has become the standard treatment for deficient mismatch repair or microsatellite instability-high (dMMR/MSI-H) colon cancer. However, there has been little progress for the majority of cases, which was mismatch-repair proficient or microsatellite stable (pMMR/MSS). For locally advanced colon cancer with T4b stage or bulky lymph nodes, neoadjuvant chemotherapy is currently widely used. Whether combining it with immunotherapy and radiotherapy can improve efficacy is worthy of exploration. TORCH-C is the first study to evaluate this combination. **Methods:** TORCH-C is a prospective, multicenter, randomized phase 2 study that enrolled patients from April 3, 2023, through September 9, 2025. A total of 120 high-risk LACC (T4/bulky N+M0 , pMMR/MSS) patients were 1:1 randomized to either an immunotherapy combined with SCRT and CAPOX chemotherapy group (group A) or a chemotherapy alone group (group B). Patients in the group B received 4 cycles of CAPOX (oxaliplatin 130 mg/m^2 intravenously day 1 and capecitabine 1000 mg/m^2 orally days 1-14). Patients in the group A received SCRT (25Gy in 5 fraction) and 4 cycles of the PD-1 inhibitor (serplulimab, 300mg intravenously day 1) combined with CAPOX. The radiotherapy target volume includes only the primary colon tumor and enlarged lymph nodes, without elective nodal irradiation. After neoadjuvant therapy, patients will be evaluated for radical colon resection. All patients will receive adjuvant chemotherapy of four cycles of CAPOX. The primary outcome was pathological complete response (pCR) rate. The secondary outcomes included tumor downstaging, R0 resection, 3-year disease free survival (DFS), 3-year overall survival (OS), 3-year local recurrence-free survival and treatment-related toxicity. **Results:** 120 patients have been enrolled and randomized. 107 patients were included in the mITT analysis (54 in group A and 53 in group B). 103 have received surgery (50 in the chemotherapy group, 53 in the radiotherapy group). The pCR rate was 10% (5/50) in chemotherapy group (group B) and 45.3% (24/53) in the radiotherapy group (group A) ($P<0.05$). The most common grade 3-4 adverse event (AE) among patients was thrombocytopenia, (22.2%, 12/54) in the group A and (18.9%, 10/53) in the group B. **Conclusions:** The combination of PD-1 inhibitor, SCRT, and chemotherapy shows promising efficacy and significantly improved pCR rates in patients with MSS/pMMR high-risk LACC. This regimen may provide a new therapeutic option to achieve R0 resection and improve long-term survival. Clinical trial information: NCT05732493. Research Sponsor: None.

3635 Poster Session

Clinicopathological characteristics of patients with minimal residual disease in stage II–III colon cancer: Interim results from the observational cohort of CLAUDIA study. First Author: Minsu Kang, Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, South Korea

Background: Circulating tumor DNA (ctDNA) monitoring for minimal residual disease (MRD) has emerged as a key prognostic biomarker in resected colon cancer. The CLAUDIA study (KCSG CO22-12, NCT05534087) is a prospective, multicenter study evaluating ctDNA-guided adjuvant therapy. It includes an observational screening cohort (Part 1) and a randomized interventional trial for MRD (+) patients (Part 2). Here, we report the baseline characteristics and MRD status of the Part 1 cohort and the clinical outcomes for patients who did not participate in Part 2. **Methods:** In Part 1, stage II or III colon cancer patients who received curative resection scheduled for adjuvant oxaliplatin-based chemotherapy (FOLFOX or CAPOX) are enrolled (N= approximately 1,200). Postoperative plasma samples collected after surgery, before starting adjuvant chemotherapy, are analyzed using a tumor-informed ctDNA assay that tracks up to 100 patient-specific mutations (IMBdx). Patients identified as MRD (+) are screened for a Part 2 randomized phase III trial (N=236) comparing mFOLFIRINOX to standard care. MRD (-) patients are managed at the investigator's discretion. **Results:** As of November 2025, a total of 809 patients were enrolled. Postoperative ctDNA was positive in 228 patients (28.2%). MRD (+) rate was significantly higher in patients with T4 tumors (40.5% vs. 22.8% in T1–3 tumors, $p<0.0001$), N2 disease (38.8% vs. 25.4% in N0–1, p=0.0007), and elevated postoperative CEA (>5 ng/mL) (42.2% vs. 26.8% in normal, p=0.013). Accordingly, MRD (+) was enriched in high-risk stage III disease (T4 or N2) (40.3% vs. 21.5% in low-risk stage III and stage II, $p<0.0001$). However, MRD (+) rates did not differ significantly by histology, tumor location, or MSI status. MRD positivity was not associated with the mutational status of the frequently altered genes in colon cancer (APC, TP53, KRAS, BRAF, ERBB2, SMAD4). We analyzed outcomes in 673 patients who did not participate in the Part 2 randomized study [92 MRD (+) and 581 MRD (-)]. In the multivariate analysis of recurrence-free survival adjusting for clinicopathologic covariates, MRD (+) was the strongest independent predictor of poor outcome (adjusted HR 5.81; 95% CI 2.65–12.74; $p<0.0001$). **Conclusions:** Postoperative ctDNA status serves as a robust prognostic biomarker in stage II-III colon cancer, correlating with advanced tumor burden. MRD (+) patients who receive standard-of-care management face a significantly increased risk of recurrence. These findings validate the utility of the ctDNA assay used and support the rationale for the ongoing CLAUDIA Part 2 trial, which investigates treatment intensification for MRD (+) patients. Clinical trial information: NCT05534087. Research Sponsor: Ministry of Health and Welfare, Republic of Korea; HA22C0062.

Relationship between GLP-1 receptor agonists on cancer recurrence and survival of patients with stage I-III colorectal cancer: A retrospective cohort study using the TriNetX database. First Author: Emily Noelle Kinsey, Department of Internal Medicine, Virginia Commonwealth University, Massey Comprehensive Cancer Center, Richmond, VA

Background: Colorectal cancer (CRC) is the second leading cause of cancer-related mortality worldwide, and obesity is a known risk factor. Glucagon-like peptide-1 receptor agonists (GLP-1RA) are increasingly used for obesity and diabetes management, making it critical to understand their long-term implications. Preclinical studies suggest a protective effect of GLP-1RA in risk for developing obesity-related malignancies, including CRC, but their long-term influence on recurrence and survival among those with CRC is not well characterized. **Methods:** A retrospective cohort study was conducted using TriNetX, a federated health research network of real-world data. Data were queried on January 22, 2026, from the Global Collaborative Network, encompassing over 190 million de-identified electronic medical records. Adult patients (> 18 years) with a diagnosis of stage I-III CRC between April 1, 2005, and April 1, 2025, were identified. The exposure group was defined as patients prescribed GLP-1RA following their CRC diagnosis. The control group was GLP-1RA nonusers. Propensity score matching (PSM) was employed, achieving balance across demographics, comorbidities, and confounding variables. The primary outcome was recurrence free survival (RFS), and the secondary outcome was overall survival (OS). Kaplan–Meier survival analysis, log-rank test, hazard ratios (HR) with 95% confidence intervals (CI), and risk ratios (RR) were used to estimate outcomes over 5-years of follow-up. **Results:** Among 20,383 patients with CRC across 19 HCOs, 839 patients per group with mean age 63.0 years remained after 1:1 PSM and exclusions, with comparable median follow-up times (710 vs 1160 days). GLP-1RA use was significantly associated with a lower risk of recurrence compared with nonusers (RR, 0.33; 95% CI, 0.25-0.45; $p < 0.001$) and improved RFS probabilities (89.0% vs 72.8%; [HR, 0.37; 95% CI, 0.27-0.50; $p < 0.001$]) at the 5-year follow-up. A significant improvement in OS was also observed in GLP-1RA users compared with nonusers (82.5% vs 71.4%; [HR 0.45; 95% CI, 0.34-0.60; $p < 0.001$]), and reduced mortality risk (RR, 0.35; 95% CI, 0.27-0.46; $p < 0.001$) compared with nonuse. Secondary analysis with 15-year median follow-up period demonstrated that these survival and recurrence benefits were sustained long term with median OS of 4,382 and 3,931 days in GLP-1RA users vs nonusers respectively. **Conclusions:** In this real-world analysis, GLP-1RA use in patients with stage I-III CRC was associated with improved RFS and OS compared to nonusers. These findings were consistent across both 5-year and 15-year follow-up periods, demonstrating a sustained association with improved outcomes in CRC. Prospective trials are needed to strengthen the evidence base for GLP-1RA use in patients with CRC and to define the underlying biological mechanisms. Research Sponsor: None.

Comparison of longitudinal circulating tumor DNA (ctDNA) and carcinoembryonic antigen (CEA) for post-operative risk stratification in colorectal cancer (CRC). First Author: Eiji Oki, Department of Advanced Medicine and Innovative Technology, Kyushu University Hospital, Fukuoka, Japan

Background: ctDNA is a reliable biomarker that outperforms CEA for detecting molecular residual disease in CRC. However, the relative prognostic performance of these biomarkers across post-operative timepoints is not fully elucidated. Characterizing these temporal dynamics can provide essential insights for optimizing biomarker-guided surveillance. **Methods:** CEA and ctDNA (Signatera, Natera, Inc.) data at 12, 24, 36, 48, 72, and 96 weeks (wk) post-surgery from patients (pt) enrolled on the CIRCULATE-Japan GALAXY study were used to perform landmarked analyses. Disease-free survival (DFS) and overall survival (OS) were evaluated among pts who were event-free at each landmark. Hazard ratios (HRs) were estimated using Cox models adjusted for clinicopathological factors. Temporal trends in prognostic strength were assessed using weighted meta-regression across post-operative timepoints. **Results:** Of the 2,825 pts with CRC [84% stage I-III, 16% stage IV; median age 69 years (range 24-95)], 49% were female; 43% received adjuvant chemotherapy while 57% went directly to surveillance. At all evaluated landmarks, ctDNA- and CEA-positivity were associated with markedly higher risk of recurrence and death compared with ctDNA- and CEA-negativity, respectively. In DFS analyses, ctDNA outperformed CEA with substantially higher HRs at all landmarks (Table 1). The prognostic strength of ctDNA increased over time, with HRs increasing from 15.15 at 12 wks to 36.87 at 72 wks post-surgery and 32.31 through 96 wks. In contrast, CEA demonstrated modest and relatively stable DFS HRs across landmarks (range 2.04 to 3.43). Meta-regression analyses demonstrated a significant temporal strengthening of ctDNA's prognostic performance for DFS (β:0.011 per wk, p=0.004), whereas no significant temporal trend was observed for CEA (p=0.33). In OS analyses, ctDNA positivity conferred high mortality risk at all landmarks, with HRs ranging from 8.40 to 14.15 (Table 1). Despite increasing prognostic association of CEA with OS at later landmarks, its HRs were lower than those of ctDNA. **Conclusions:** ctDNA-positivity consistently outperforms CEA in predicting disease recurrence and OS. ctDNA provides strong risk stratification at early postoperative time points, and its prognostic accuracy continually improves during longitudinal surveillance, confirming its superior performance for early risk assessment and personalized serial disease monitoring during surveillance. Clinical trial information: UMIN000039205. Research Sponsor: None.

Neoadjuvant tislelizumab plus chemotherapy in MSS/pMMR high-risk locally advanced colon cancer: Updated analysis results from a phase 2 trial. First Author: Minglin Lin, The First Affiliated Hospital of Guangxi Medical University, Nanning, Guangxi, China

Background: Patients with locally advanced colon cancer (LACC) have a poor prognosis, and those with N+ or T4 staging are prone to developing metastases. Only about 5% pathological complete response rates were observed in neoadjuvant chemotherapy. We conducted a single-arm, phase II trial to evaluate the efficacy and safety of immunotherapy combined with chemotherapy in locally advanced colon cancer. **Methods:** LACC patients clinically staged as T4 or N2 with histologically confirmed microsatellite stable/mismatch repair proficient (MSS/pMMR) type untreated colon adenocarcinoma are eligible for enrollment. Participants received 2-6 cycles of neoadjuvant therapy consisting of capecitabine and oxaliplatin (CAPOX) plus tislelizumab, followed by complete mesocolic excision. The primary endpoint was the pathological complete response (pCR) rate. This study was registered at ClinicalTrials.gov (NCT06124378). **Results:** A total of 61 patients were enrolled with a median age of 54 years (IQR 43–62). 35 (57%) of the recruited patients had a cT4 tumor and 47 (77%) of the patients had N2. All patients received neoadjuvant CAPOX plus tislelizumab, while three patients were excluded from activity analyses due to adverse events and the patient decision. Among the remaining 58 patients, 16 (28%) patients received 2 cycles, 39 (67%) patients completed 4 cycles, and 3 patients (5%) received 6 cycles prior to surgery. 14% patients achieved clinical complete response and the overall response rate was 91% based on clinical efficacy, with no cases of progressive disease observed. The regimen achieved a pathological complete response (pCR) rate of 41.4%, with all patients undergoing R0 resection. The major pathological response rate was 51.7% (95% CI 38.6 to 64.6). In subgroup analyses, patients with right-sided tumors exhibited higher pCR rates (16 [47%, 95% CI 30–65] of 34, compared to 8 [33%, 95% CI 17–54] of 24 for left-sided cases. However, no statistically significant differences were observed between the subgroups. Treatment-related adverse events of any grade occurred in 52 (85.2%) of 61 patients. The most common adverse events were peripheral sensory neurotoxicity (37 [61%] of 61) and decreased appetite (31 [51%]). Grade 3 drug-related serious adverse events occurred in 8 (13%) patients while no grade 4–5 adverse events occurred. **Conclusions:** This prospective trial demonstrates that neoadjuvant tislelizumab plus CAPOX provides a promising treatment strategy with encouraging antitumor activity and a manageable safety profile for MSS/pMMR locally advanced colon cancer. Clinical trial information: NCT06124378. Research Sponsor: None.

Association of CT-based deep learning–derived consensus molecular subtypes with survival outcomes in locally advanced colon cancer: A secondary analysis of the phase III OPTICAL trial. First Author: Sifan Qi, Department of Medical Oncology, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: The Consensus Molecular Subtypes (CMS) provide a robust framework for the biological stratification of colorectal cancer (CRC), but their clinical use is limited by the cost and complexity of transcriptomic profiling. We evaluated the prognostic and predictive utility of a non-invasive, CT-based deep learning model for CMS classification (CT-CMS) in patients with locally advanced colon cancer (LACC) enrolled in the OPTICAL trial. **Methods:** Patients from the OPTICAL trial with available baseline venous-phase contrast-enhanced CT images were included. A previously validated deep learning model was applied to predict CMS subtypes (CMS1-4). The association between CT-CMS and survival outcomes, including disease-free survival (DFS) and overall survival (OS), was assessed using multivariable Cox proportional hazards regression models adjusted for age, sex, TNM stage, and tumor location. **Results:** The study included 394 patients, with 189 patients in the neoadjuvant chemotherapy (NAC) group and 205 in the upfront surgery group. The median follow-up was 48.0 months. The distribution of CT-CMS subtypes was as follows: CMS1 (n=64, 16.2%), CMS2 (n=135, 34.5%), CMS3 (n=69, 17.5%), and CMS4 (n=126, 32.0%). In the total population, CMS3 showed the most favorable outcomes, with a 3-year OS rate of 96.1% (95% CI, 90.9%-100.0%) and a 3-year DFS rate of 87.9% (95% CI, 80.3%-96.2%). Multivariable analysis confirmed that CMS3 was independently associated with superior prognosis compared to CMS1 (adjusted hazard ratio [aHR] = 0.39, 95% CI 0.17-0.92, p = 0.030). In the NAC group, CMS was a significant independent prognostic factor for DFS (p = 0.044), with CMS3 (p = 0.027) and CMS2 (p = 0.046) showing significant improvement over CMS1. Notably, patients with CMS2 tumors exhibited significant survival benefits from neoadjuvant chemotherapy compared with upfront surgery, with improved OS (aHR = 0.08, 95% CI 0.01-0.62, p = 0.016, log-rank p = 0.002) and DFS (aHR = 0.45, 95% CI 0.20-0.99, p = 0.047). **Conclusions:** CT-based CMS3 was associated with favorable prognosis, while CMS2 identified patients were most likely to benefit from neoadjuvant chemotherapy. These findings support the clinical utility of CT-CMS as a non-invasive, pre-treatment tool for molecular stratification in LACC. Neoadjuvant chemoradiotherapy with or without PD-1 blockade in pMMR/MSS low rectal cancer patients (CHOICE II): A multi-center, open-label, randomized controlled trial. First Author: Wei Zhang, Department of Colorectal Surgery, Changhai Hospital, Naval Medical University, Shanghai, China

Background: Neoadjuvant chemoradiotherapy (nCRT) combined with PD-1 blockade has shown great potential for improving the clinical complete response (cCR) rate in low rectal cancer patients in a previous exploratory clinical trial. This study aimed to further verify the efficacy and safety of nCRT with PD-1 blockade in patients with pMMR/MSS low rectal cancer. **Methods:** We conducted a prospective, multicenter, randomized, open-label trial (NCT05215379) with two parallel groups across 11 centers. Patients with confirmed $cT_{1-3a}N_{0-1}M_0$ rectal adenocarcinoma of the pMMR/-MSS type, with an inferior margin of 5 cm from the anal verge, were randomly assigned to either the intervention group, receiving 50 Gy (2 Gy/d*25d) radiotherapy, 4 cycles of PD-1 blockade (sintilimab) and 2 cycles of CAPOX, or the control group, receiving 50 Gy (2 Gy/d*25d) radiotherapy and 2 cycles of CAPOX. After completion of neoadjuvant treatment, patients were reassessed to determine clinical efficacy. If patients achieved cCR, the Watch-and-Wait (W&W) approach was performed. If near-cCR (ncCR) was achieved, patients were re-evaluated by a multidisciplinary team to determine whether W&W, local excision, or total mesorectal excision (TME) should be performed. Patients assessed with an incomplete clinical response (iCR) received TME. The primary endpoint was the cCR rate, and the key secondary endpoints included the organ preservation (W&W and local excision) rate, disease free survival (DFS), and overall survival (OS). **Results:** From July 2022 to December 2024, a total of 201 patients with low rectal cancer were screened at 11 medical centers and 180 patients were finally randomly assigned. A total of 169 patients were included in the primary analysis (85 patients in the intervention group and 84 in control group). The cCR rates were 36.5% in the intervention group compared to 17.9% in the control group (p=0.007). There were 48 and 51 patients who underwent surgery in the intervention and control groups, respectively, and the pathological complete response (pCR) rates were 25.0% and 15.7% (p=0.249). The overall complete response (cCR+pCR) rates were 50.6% and 27.4% (p=0.002) in the intervention and control groups. The overall occurrence rates of adverse events (AEs) were 72.9% in the intervention group compared to 66.3% in the control group (P>0.05), and the occurrence of severe AEs (Grade III or IV) was comparable between the two groups (7.1% vs 3.8%, p=0.34). Due to the limited follow-up duration, the DFS and OS data are immature. **Conclusion:** In this trial, the results showed that nCRT combined with sintilimab significantly improved the cCR rate in patients with pMMR/MSS low rectal cancer with a tolerable safety profile. Clinical trial information: NCT05215379. The value of tumor deposits in prognosis evaluation and clinical stage optimization of colorectal cancer: A real-world population-based retrospective cohort study. First Author: Chang Wang, The First Hospital of Jilin University, Changchun, China

Background: The location and weight of tumor deposit (TD) in the TNM staging system may be seriously underestimated, which affects the accuracy of TNM staging in predicting prognosis. We conducted a study to further clarify the role of TD in predicting the prognosis, the weighting of TD, and the possible value of optimizing the TNM staging system of CRC. **Methods:** The subject was CRC patients diagnosed by postoperative pathology in our hospital from January 2013 to December 2021, including 2642 TD (+) and 1162 TD (-) patients. TD (-) patients were regarded as the control group according to category matching principle of the diagnosis, treatment and the period as TD (+) patients. Cox univariate and multivariate were analyzed. K-M curve was applied to analyze survival. **Results:** (1) The clinical and pathological characteristics are as follows: The TD positive rate was 25.3%. In stage I-III, more advanced tumor T and N-stage, primary sites in the left-sided colon or rectum, poorer histologic grade, and more nerve invasion and vascular infiltration (all $p<0.05$) were observed in TD (+) patients. In stage IV patients, TD (+) patients were more likely to have multiple metastases ($p<0.05$). (2) Patients with TD (+) had worse prognosis than patients with TD (-), with shorter DFS and OS in stage I-III (3-y DFS and OS rate, all $p<0.05$), with shorter PFS in stage IV (3-y PFS rate, $p<0.05$). The univariate and multivariate analysis showed that TD (+) was one of independent prognosis factors in CRC patients. And the prognosis shows a trend of getting worse as the number of TD increases. (3) The relationship between TD and N staging: Patients with TD (+), LN (-) had similar OS as patients with TD (-), LN (+) (3-y OS rate, p=0.418). Patients with TD (+), LN (-) had similar OS as patients with TD (-), N2 (3-y OS rate, p=0.695). Patients with TD (+), LN (-) had shorter OS than patients with N2a, TD (-) (3-y OS rate, p=0.029) and longer OS than patients with N2b, TD (-) (3-y OS rate, p=0.034). When TD and LN were counted together for N-staging, the OS between patients with new N2 and primary N2 was similar (3-y OS rate, p=0.382). (4) The relationship between TD and M staging: The survival of patients with TD more than 4 was similar to stage IV patients (2-y OS rate , p=0.061); when the number of LN more than 6 and TD (+) coexisted, OS was similar with stage IV patients (2-y OS rate, p=0.554). When TD and M were counted together for M-staging, the OS between patients with new M1 and primary M1 was similar (3-y OS rate: p=0.149). **Conclusions:** TD (+) patients are related with unfavorable prognostic clinical and pathological factors. TD was one independent prognosis factor in CRC patients. The location and weight of TD in the TNM staging system may be seriously underestimated. The prognostic accuracy of TNM staging may be improved when the weight of the presence and quantity of TD is increased. Clinical trial information: 2023-ks-143. Research Sponsor: None.

Updated 5-year survival outcomes of short-course radiation followed by mFOLFOX-6 plus avelumab in locally advanced microsatellite-stable rectal adenocarcinoma: The Averectal phase II study. First Author: Ali Shamseddine, American University of Beirut Medical Center, Beirut, Lebanon

Background: Total neoadjuvant therapy (TNT) for microsatellite-stable (MSS) locally advanced rectal cancer consists of induction or consolidation chemotherapy combined with either long-course chemoradiation (LCCRT) or short-course radiation therapy (SCRT). While TNT has yielded variable outcomes across studies, it has consistently improved pathologic complete response (pCR) rates and paved the way for non-operative management strategies. However, the use of SCRT within TNT has been associated with higher rates of local recurrence. The integration of immunotherapy into total neoadjuvant therapy (TNT) improves outcomes in LARC, particularly pathologic complete response (pCR), which may translate into improvements in disease-free survival (DFS) and overall survival (OS), in addition to improvement in local recurrence rate (LRR) especially when used with SCRT, potentially through synergistic effects with radiotherapy. **Methods:** The Averectal trial is an investigator-initiated, open-label, single-arm, multicenter, phase II study including 44 patients. 40 patients with LARC completed treatment with SCRT (5 Gy x5 fractions) followed by 6 cycles of mFOLFOX-6 plus avelumab every 2 weeks, followed by TME. The primary outcome was pCR vs. historical control. Secondary outcomes were 3-year DFS, LRR and the association of the ImmunoScore (IS) with outcomes including pCR. **Results:** 15/40 (37.5 %) patients achieved pCR compared to 16 % in the historical control group with statistically significant p = 0.025, and 27/40 (67.5 %) had a major pathologic response. Patients who achieved pCR had a higher mean IS compared with those who did not (68 vs. 52, p = 0.049). With a median follow up of 72.8 months (range 15.4-97.1), the median OS and DFS were not reached. The mean OS and DFS were 85.3 months and 79 months respectively, and the 5-year OS and DFS were 81.9% and 74.6%. Only 2/40 patients had local recurrence, accounting for a LRR of 5%. In patients with high versus low IS, median OS was not reached in either group (p = 0.9), with mean OS of 79.3 months versus 84.7 months, respectively. Similarly, median DFS was not reached, although there was a trend towards improved DFS in the high IS group (p = 0.175), with mean DFS of 77.6 months versus 70.7 months for high and low IS, respectively. **Conclusions:** The addition of avelumab to TNT in patients with MSS LARC resulted in a statistically significant increase in pCR, notably among those with high IS, and was associated with continued improvement in survival outcomes at 5 years. Clinical trial information: NCT03503630. Research Sponsor: This study was financially supported by Merck Healthcare KGaA; CrossRef Funder ID: 10.13039/100009945.

Immunotherapy-based total neoadjuvant therapy with or without short-course radiotherapy for locally advanced rectal cancer: Preliminary results of TORCH-iTNT. First Author: Yaqi Wang, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: In patients with proficient mismatch repair (pMMR) locally advanced rectal cancer (LARC), the integration of PD-1 inhibitor into total neoadjuvant chemoradiotherapy (iTNT) has demonstrated promising potential to enhance complete response (CR) rates and facilitate organ preservation. However, the combined use of radiotherapy and surgical intervention frequently leads to increased functional impairment relative to either modality administered independently. Concurrently, the combination of chemotherapy and PD-1 inhibitor has been shown to promote tumor downstaging, thereby enabling sphincter-preserving surgery while mitigating radiation-induced injury. This trial evaluates oncological efficacy and functional outcomes of two iTNT regimens: CAPOX plus PD-1 inhibitor with or without SCRT in neoadjuvant treatment of pMMR LARC patients. **Methods:** The TORCH-iTNT trial (NCT06281405) is a prospective, multicenter, randomized phase II study involving 192 patients with pMMR LARC (T3-4/N+M0). Participants were randomized into Group A (6 cycles of CAPOX plus toripalimab) or Group B (SCRT [25Gy/5Fx] followed by 6 cycles of CAPOX plus toripalimab). Patients achieving clinical complete response (cCR) were offered a watch-and-wait (W&W) strategy, while those without cCR were advised to undergo surgery. Group A patients with positive circumferential margins received adjuvant chemoradiotherapy. The primary endpoint was CR rate (pathological complete response [pCR] plus cCR). Secondary endpoints included organ preservation rate, anorectal function, adverse effects, and survival outcomes. **Results:** By December 31, 2025, 192 patients were enrolled, with 137 completing treatment (Group A: 65; Group B: 72). Baseline characteristics were balanced, with 97.1% (133/137) exhibiting at least one high-risk feature: lower tumor location ($\leq$5cm), cT4, cN2, MRF+, or EMVI+. In Group A, 5 patients achieved cCR and adopted W&W, compared to 22 in Group B. Of the 54 and 49 patients in Group A and B who underwent surgery, pCR was observed in 19 (35.2%) and 22 (44.9%) cases, respectively. Five non-cCR patients in Group A declined surgery or were still undergoing treatment. Disease progression occurred in one patient per group. The overall CR rates were 36.9% (24/65) in Group A and 61.1% (44/72) in Group B. The most frequent grade 3-4 toxicity was thrombocytopenia (Group A: 12.3%; Group B: 12.5%). **Conclusions:** This study is the first comparative analysis of two iTNT regimens in LARC. Unprecedentedly, neoadjuvant CAPOX plus PD-1 inhibitor achieved a promising CR rate in pMMR LARC, and this CR rate can be further enhanced with the addition of SCRT prior to immunochemotherapy. Further follow-up is necessary to assess long-term efficacy and functional endpoints. Clinical trial information: NCT06281405. Research Sponsor: National Natural Science Foundation of China (Grant No: 82473237).

Impact of CAPOX combined with traditional Chinese medicine (TiaoPi AnChang Decoction) on disease-free survival in patients with stage III or high-risk stage II colorectal cancer: An updated report of a randomized, double-blind, placebo-controlled trial. First Author: Jincheng Zhang, Beijing University of Chinese Medicine, Beijing, China

Background: Colorectal cancer (CRC) at early and mid-stages has significantly different prognoses from advanced CRC. Preventing the progression to advanced disease after surgery is crucial for improving survival and reducing healthcare burden. Multiple retrospective studies have shown that Tiaopi Anchang Decoction (TPACD), an oral formula of edible botanical drugs, can reduce recurrence and metastasis risk in CRC when combined with CAPOX. However, the evidence is limited by confounding factors and reporting biases. This study aims to test the hypothesis that CAPOX combined with TPACD can further improve disease-free survival (DFS) in patients with stage III or high-risk stage II CRC. **Methods:** The study recruited patients from 4 departments of China-Japan Friendship Hospital. It enrolled stage III or high-risk stage II CRC patients undergoing CAPOX and randomly assigned patients in a 1:1 ratio to either the TPACD group (30 mL orally, twice daily) or the placebo group (matched placebo). The trial duration covered 4 chemotherapy cycles, during which CAPOX-induced adverse reactions, quality of life (QoL), safety, and survival outcomes were assessed. The primary endpoint was DFS, while the secondary endpoints included overall survival, the incidence of CAPOX-induced adverse reactions, and QoL score (EORTC QLQ-C30). Kaplan-Meier analysis and Cox proportional hazards regression model were used to evaluate the correlation between CAPOX combined with TPACD and DFS. **Results:** From December 2022 to September 2024, 496 patients were screened, and 108 were enrolled. The 108 patients were randomly assigned in a 1:1 ratio to the TPACD group or placebo group. 42% were female, the average age was 58 years, and 66% had stage III disease. The interim report has confirmed that TPACD is safe, significantly reduced CAPOX-induced adverse reactions, and improved QoL. Median follow-up time was 28 months, with 17 DFS events (4 TPACD, 13 placebo) and no deaths. Kaplan-Meier analysis estimated 2-year DFS rates of 93.3% for TPACD and 74.7% for placebo. Log-rank testing revealed a statistically significant difference between the two groups (χ^2 = 5.329, P = 0.021). CAPOX combined with TPACD significantly reduced the occurrence of DFS events (multivariable hazard ratio [HR] 0.23, 95% confidence interval [CI] 0.073-0.736, P= 0.01) and this effect was not influenced by age, sex, primary tumor site, or TNM stage ($P_{interaction} > 0.05$). **Conclusions:** For patients with stage III and high-risk stage II CRC, TPACD is a well-acceptable complementary therapy. The combination of CAPOX and TPACD not only reduces CAPOX-induced adverse reactions and improves QoL, but also further extends the DFS. Further disclosure of survival data could help optimize adjuvant chemotherapy regimens for CRC. Clinical trial information: ChiCTR2200065759. AI-derived tumor microenvironment features and recurrence risk in microsatellite-stable colon cancer after adjuvant chemotherapy. First Author: Changhee Park, Seoul National University Hospital, Jongno-Gu, NA, South Korea

Background: Despite adjuvant chemotherapy, a substantial number of patients with stage II–III microsatellite stable (MSS) colon cancer relapse. While clinicopathologic and circulating tumor DNA (ctDNA) analysis can be used for risk stratification, there is a need for further improvement in risk prediction. Here, we utilized artificial intelligence (AI) applied to hematoxylin and eosin (H&E) slides, which enables efficient and comprehensive assessment of tumor microenvironment (TME). **Methods:** We retrospectively analyzed TME of high-risk stage II and III colon cancer patients treated with surgery and adjuvant fluoropyrimidine and oxaliplatin chemotherapy. AI-based quantification of tumor area, stromal area, and TME cells (lymphocytes, fibroblasts, macrophages, and endothelial cells) was performed using Lunit SCOPE IO. We developed a generalized linear model with a backward elimination process integrating AI-derived TME features with conventional clinicopathologic variables (T stage, N stage, tumor differentiation, lymphatic invasion, venous invasion, and perineural invasion). The optimal cutoff for distinguishing between high-risk and low-risk patients for relapses was determined using the Youden index derived from the model's receiver operating characteristic curve. We evaluated how the model stratified the risk group in the training cohort and validated it in an independent cohort. **Results:** In the training cohort (n = 390), high stromal lymphocyte density (HR 0.42, 95% CI 0.26 – 0.68), high tumor-stromal ratio (HR 0.46, 95% CI 0.29 – 0.73), and low stromal area per fibroblast (HR 0.33, 95% CI 0.21 – 0.53) were associated with favorable DFS among the TME features. In the multivariate analysis, high stromal lymphocyte density (adj HR 0.57, 95% CI 0.35 – 0.95) and low stromal area per fibroblast (adj HR 0.58, 95% CI 0.33 – 0.99) showed significant associations with DFS independent of clinicopathological covariates. The final TME-integrated model, incorporating N stage, lymphatic invasion, stromal lymphocyte density, and stromal area per fibroblast, stratified patients into high- and low-risk groups with 3-year DFS rates of 72.3% and 93.8%, respectively (adjusted HR for high risk 3.29, 95% CI 1.98 – 5.46). The model identified high-risk patients irrespective of clinicopathological risk features. For example, high-risk status was associated with worse outcomes among patients with N2 disease (adjusted HR 6.57, 95% CI 1.58 – 27.34), and also among patients with N0 or N1 disease (adjusted HR 2.49, 95% CI 1.27 – 4.87). The model was validated in an external independent cohort (n = 260; adjusted HR for high-risk 3.68, 95% CI 1.60 – 8.48). **Conclusions:** TME-integrated model combining AI-derived TME features with clinicopathologic factors significantly improved recurrence risk stratification in MSS colon cancer receiving adjuvant chemotherapy. Research Sponsor: None.

Single-cell profiling of the tumor microenvironment in pMMR/MSS rectal cancer treated with neoadjuvant PD-1 inhibitor combined with FOLFOXIRI and radiotherapy: Insights from the PANFORTE trial. First Author: Chi Zhou, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University, Guangzhou, China

Background: Programmed cell death-1 (PD-1) inhibitor-based combination therapies have emerged as a promising neoadjuvant strategy for locally advanced rectal cancer (LARC). However, the underlying tumor microenvironment (TME) dynamics during multimodal chemoimmunoradiotherapy remain incompletely understood. This study leveraged single-cell RNA sequencing to systematically map the TME remodeling induced by neoadjuvant PD-1 inhibitor combined with chemoradiotherapy in the PANFORTE trial (NCT06099951), aiming to identify cellular correlates of therapeutic response and resistance in pMMR/MSS rectal cancer. **Methods:** Pre- and post-treatment tumor samples from patients with pMMR/MSS rectal cancer enrolled in the PANFORTE trial and treated with neoadjuvant FOLFOXIRI, PD-1 inhibitor, and radiotherapy were subjected to single-cell RNA sequencing. Following stringent quality control, 227,447 high-quality cells from 50 samples were retained and annotated into seven major lineages. Cellular compositional changes across response groups were quantified using the observed-to-expected (Ro/e) index. Fibroblast subpopulations were identified via non-negative matrix factorization (NMF), and pseudotime trajectory analysis of myeloid cells was performed with Monocle 2. **Results:** Single-cell profiling revealed marked TME remodeling after neoadjuvant therapy. Complete responders (CR) showed significant stromal reduction, while non-responders (NCR) retained higher proportions of myeloid cells, endothelial cells, and fibroblasts. CR tumors exhibited enrichment of effector populations (NK cells, $CD8^+$ effector memory T cells), whereas NCR tumors expanded immunosuppressive subsets (regulatory T cells, naïve T cells). Fibroblast subclustering identified inflammatory cancer-associated fibroblasts (iCAFs) as enriched in NCR. Pseudotime analysis demonstrated that myeloid cells in CR differentiated toward M1-like states, while NCR samples were biased toward M2-like programs. **Conclusions:** This study delineates distinct TME landscapes underlying differential responses to neoadjuvant FOLFOXIRI, PD-1 inhibitor, and radiotherapy in pMMR/MSS rectal cancer. Responders are characterized by cytotoxic immune activation and stromal depletion, whereas non-responders maintain an immunosuppressive milieu rich in iCAFs and M2-like myeloid cells. These findings provide mechanistic insight into treatment resistance and highlight potential cellular targets for enhancing therapeutic efficacy. Clinical trial information: NCT06099951. Research Sponsor: None.

Rates of metachronous colorectal cancer or secondary Lynch syndrome–related cancers in patients with non-metastatic colorectal cancer. First Author: Emily M. Russell, Labcorp (formerly Invitae Corp.), San Francisco, CA

Background: Lynch syndrome (LS) increases metachronous colorectal cancer (CRC) risk up to 5-fold, while extended resection surgery after initial CRC can reduce this risk. Prior work showed that pre-surgical germline genetic testing (GGT) was more likely to result in extended resections, especially for *MLH1/MSH2* carriers. We evaluated the rates of metachronous CRC following surgery, along with rates of other LS cancers following CRC diagnosis. **Methods:** GGT and insurance claims (Komodo Healthcare Map) data for adults with non-metastatic colon (CC) or rectal (RC) cancer and CRC surgery from 2015-25, ≥6 months of cancer-free claims pre-CRC diagnosis, ≥6 months of claims post-CRC surgery, and *EPCAM/MLH1/MSH2/MSH6/PMS2* GGT. Statistical tests compared metachronous CRC rates (new CRC ≥6 months post-surgery) following partial (partial/segmental colectomy or proctectomy) or extended (total colectomy or total proctocolectomy) resections by GGT result. Multivariable logistic regression modeled variables associated with metachronous CRC or other LS cancers. **Results:** Of 4,050 CRC patients (3,905 CC, 145 RC), 530 (13.1%) were LS-positive. 3,860 (95.3%) had partial (12.2% LS-positive) and 190 (4.7%) had extended resections (32.1% LS-positive). Post-surgery claims were available for a mean (standard deviation) of 47.7 (28.0) months. 251 (6.2%) patients with CRC had metachronous CRC post-surgery (6.1% partial vs. 8.9% extended resection, p=0.145). 282 (7.0%) patients with CRC were diagnosed with other LS cancers (54 [10.2%] LS-positive vs. 228 [6.5%] negative/variant of unknown significance (LS-negative), p=0.002). Patients with other LS cancers were diagnosed an average of 31.6 (23.9) months after initial CRC diagnosis (LS-positive: 29.0 [26.7], LS-negative: 32.2 [23.2]). The most common other LS cancer was prostate for men (80/1,822, 4.4%) and endometrial/uterine for women (55/2,228, 2.5%). Increased odds of metachronous CRC were associated with RC (compared to CC) (odds ratio [OR]: 5.1, 95% confidence interval [CI]: 3.3-8.0) and more months of available post-surgery claims (OR: 1.02, CI: 1.01-1.02). Increased odds of other LS cancers were associated with *MLH1/MSH2/EPCAM* carriers (compared to LS-negative) (OR: 2.0, CI: 1.3-3.1), older age (1.04, 1.03-1.05), male sex (1.6, 1.3-2.1), physician-reported Black race (1.6, 1.0-2.4) (compared to White), and more months of available post-surgery claims (1.02, 1.02-1.03). **Conclusions:** Patients with pathogenic variants in *MLH1/MSH2/EPCAM* had 2x higher odds of a second LS cancer diagnosis. 1 out of 10 patients with CRC and LS had a second LS cancer, and more than half (55.6%) of second diagnoses were within 2 years of initial CRC diagnosis. These findings highlight the importance of integrating genetic testing and comprehensive Lynch syndrome surveillance into patient care at the time of initial CRC diagnosis. Research Sponsor: None.

TGF-β signaling alterations in bevacizumab-treated early-onset colorectal cancer: An artificial intelligence–enabled precision oncology study in diverse populations. First Author: Erika Ruiz-Garcia, Gastrointestinal Oncology Department & Translational Medicine Laboratory, Instituto Nacional de Cancerología, Mexico City, DF, Mexico

Background: The transforming growth factor–β (TGF-β) signaling pathway plays a complex, context-dependent role in colorectal cancer (CRC), functioning in tumor suppression, immune modulation, and metastatic progression. Its interaction with anti-angiogenic therapy remains poorly defined, particularly across age and ancestry groups. Early-onset CRC (EOCRC) may exhibit distinct TGF-β pathway biology. We investigated ancestry-, age-, and treatment-associated patterns of TGF-β signaling alterations and their prognostic relevance in bevacizumab-treated CRC using an artificial intelligence–enabled precision oncology framework. **Methods:** We performed a retrospective analysis of 2,717 CRC patients from publicly available datasets with integrated genomic, clinical, and treatment annotations. Eligible cases included colorectal adenocarcinoma with sequencing data and documented bevacizumab exposure. Patients were stratified by age (< 50 years [EOCRC] vs. ≥50 years [LOCRC]), ancestry (H/L vs. non-Hispanic White [NHW]), and treatment status. TGF-β pathway alterations, including mutations in core signaling components (e.g., TGFBR2), were analyzed as categorical variables. Differences in mutation frequencies were assessed using Fisher's exact test. Overall survival (OS) was evaluated using Kaplan–Meier methods and Cox proportional hazards models. Conversational AI agents facilitated reproducible cohort construction and multi-dimensional querying. Analyses were exploratory. **Results:** Marked ancestry-, age-, and treatment-specific differences in TGF-β alterations were observed. Among bevacizumab-unexposed EOCRC, H/L tumors demonstrated substantially higher TGF-β alteration frequencies compared with NHW tumors (31.9% vs. 0.2%, $p = 2 \times 10^{-16}$). In NHW EOCRC, bevacizumab exposure was associated with increased TGF-β alterations relative to unexposed tumors (25% vs. 0.2%, $p = 2 \times 10^{-16}$). Similarly, bevacizumab-treated NHW LOCRC exhibited higher TGF-β alteration frequencies than unexposed counterparts (58% vs. 15.4%, $p = 2.2 \times 10^{-16}$). Among bevacizumab-unexposed LOCRC, H/L tumors showed higher TGF-β alterations than NHW tumors (34.2% vs. 18.0%, $p = 2.41 \times 10^{-5}$). In NHW LOCRC, bevacizumab-exposed tumors had a lower frequency of TGFBR2 alterations compared with unexposed tumors (1.3% vs. 7.1%, p = 0.03). Survival analyses suggested that TGF-β alterations were associated with improved OS in bevacizumab-unexposed NHW LOCRC, with borderline statistical significance (p = 0.08). **Conclusions:** The enrichment of TGF-β alterations in specific bevacizumab-exposed and ancestry-defined subgroups highlights potential interactions between angiogenic therapy and TGF-β pathway biology. These findings highlight the importance of incorporating ancestry-aware frameworks to advance precision oncology. Cost-effectiveness analysis of aspirin and structured exercise as adjuvant therapy in localized colorectal cancer. First Author: Malek B. Hannouf, Arthur J. E Child Comprehensive Cancer Centre, Calgary, AB, Canada

Background: The ALASCCA trial demonstrated that 160 mg of aspirin daily for 3 years reduced the risk of localized colorectal cancer recurrence in patients with PIK3CA exons 9/20 (group A) or PIK3R1/PTEN/other PIK3CA alterations (group B). The CHALLENGE trial demonstrated that increasing recreational aerobic activity above baseline through a 3-year structured exercise program reduces the risk of colon cancer recurrence. These interventions have not been adopted into Canadian clinical practice (CCP), and we evaluated the cost-effectiveness of strategies to implement them as adjuvant therapy for localized, operable colorectal cancer from the Canadian public healthcare perspective. **Methods:** We developed a decision model to project clinical and economic consequences of six strategies: (1) "CCP," defined as no exercise or aspirin interventions; (2) "Aspirin for group A PI3K alterations," defined as testing for group A PI3K alterations and treating positive patients with aspirin; (3) "Aspirin for group A/B PI3K alterations," defined as testing for group A/B PI3K alterations and treating positive patients with aspirin; (4) "Aspirin for all," defined as treating all patients with aspirin regardless of PI3K status; (5) "Structured exercise alone," defined as initiating all patients on a structured exercise program with no aspirin intervention; and (6) "Aspirin for group A/B PI3K alterations and structured exercise," defined as testing for group A/B PI3K alterations, treating positive patients with aspirin, and initiating all patients on a structured exercise program. The model was parameterized using survival data from the ALASCCA and CHALLENGE trials, and cost and utility data from Alberta, Canada, and Canadian sources. Costs are presented in 2025 Canadian dollars. Future costs and benefits were discounted at 1.5%. **Results:** Compared with the CCP, all interventional strategies were associated with greater QALY gains and lower per-person costs, resulting in overall cost savings (Table). The "aspirin for group A/B PI3K alterations and structured exercise" strategy emerged as the dominant intervention, yielding the highest QALYs gained and greatest cost savings per person. Implementing this strategy into CCP would avert disease recurrence in 940 patients per year, generate 2,625 total QALYs annually, and produce total budget savings of $399 million per year. **Conclusions:** The integration of PI3K group A/B–guided aspirin therapy with structured exercise as adjuvant treatment for localized colorectal cancer should be adopted into CCP, given its considerable societal benefit. Research Sponsor: None.

Strategy	Inc. QALY gained/ pers.	Cost saving/ pers.
CP	Ref	Ref
Aspirin for group A PI3K alterations	0.05	9,400
Aspirin for group A/B PI3K alterations	0.12	20,200
Aspirin for all	0.07	14,700
Structured exercise alone	0.13	23,700
Aspirin for group A/B PI3K alterations and structured exercise	0.22	33,700

Efficacy and safety of tislelizumab as neoadjuvant therapy combined with MRD monitoring in locally advanced dMMR/MSI-H colon cancer: A prospective pilot study. First Author: Miaoqing Wu, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangzhou, China

Background: PD-1 blockade has demonstrated high efficacy in metastatic and neoadjuvant settings for dMMR/MSI-H colorectal cancer. This study aimed to evaluate the efficacy and safety profile of neoadjuvant tislelizumab monotherapy in locally advanced dMMR/MSI-H colon cancer patients, with integrated minimal residual disease (MRD) monitoring. **Methods:** Histologically confirmed locally advanced dMMR/MSI-H colon adenocarcinoma are eligible for enrollment. Participants received 4 cycles of neoadjuvant tislelizumab (200 mg IV Q3W) followed by clinical response assessment. Patients continued receiving 4 additional cycles or underwent radical surgery based on the multidisciplinary team (MDT) decision. Non-operative management (NOM) was a choice of cCR patients after 8 cycles of treatment. MRD status was assessed by a tumor-informed, bespoke ctDNA assay (HuaJianwei) at baseline, during and post-treatment. The primary endpoint was pCR rate. Secondary endpoints included cCR rate, MPR rate, DFS, NOM rate, biomarker exploration, and safety. **Results:** Forty patients were enrolled between November 2022 and May 2025 (median follow-up: 13.58 months) and one requested to withdraw from the study. Twenty-eight (71.8%) underwent surgery, including 8 patients who received less than 6 cycles of neoadjuvant therapy, 18 patients who completed 8 cycles, and 2 patients who received more than 8 cycles based on MDT decision. Of resected patients, 22 (78.6%) achieved pCR and 26 (92.9%) achieved MPR. Nine patients opted for NOM due to cCR, with an overall CR rate of 79.5%. Grade 3 irAEs occurred in 4 patients (10.3%), including pneumonitis (n=2), renal insufficiency (n=1), and stroke (n=1). No treatment-related deaths occurred. Baseline MRD testing was completed in 29 patients, 28 (96.6%) of whom were positive. Rapid clearance of MRD was observed in 48.3% (14/29) of patients after 1 cycle and 75.9% (22/29) of patients after 2 cycles. Only one patient (1/10) remained MRD-positive post-treatment due to pneumonitis-related therapy discontinuation. **Conclusions:** Neoadjuvant tislelizumab monotherapy confers favorable efficacy and a manageable safety profile in locally advanced dMMR/MSI-H colon cancer with high pCR rates and feasible NOM for cCR patients. MRD monitoring provides valuable, real-time assessment of treatment response to guide surgical and surveillance decisions. Longer follow-up is needed to confirm response durability, particularly in NOM patients. Clinical trial information: NCT06262581. Research Sponsor: None.

Consensus molecular subtypes, mutational features, and circulating tumor DNA dynamics in colorectal cancer: A real-world clinico-genomic analysis. First Author: Imad Shureiqi, Division of Hematology and Oncology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI

Background: Consensus molecular subtypes (CMS) define biologically distinct colorectal cancer (CRC) groups with differences in tumor microenvironment, genomic features, and prognosis. While CMS classification is well established in tissue-based transcriptomic studies, its relationship with circulating tumor DNA (ctDNA) dynamics and molecular features in real-world clinical practice remains incompletely characterized. We evaluated CMS subtype distribution, mutational characteristics, and ctDNA detection patterns in a large real-world CRC cohort. **Methods:** Patients with CRC who underwent whole-transcriptome sequencing via Altera (Natera, Inc.) testing were identified from Natera's real-world clinico-genomic database. CMS subtype assignment was based on the whole-transcriptome sequencing, and then correlated with Signatera results, a personalized, tumor-informed ctDNA assay. In patients with stage II–III CRC, ctDNA positivity was assessed during the MRD window (1–10 weeks post-surgery) and during post-MRD surveillance (>10 weeks post-surgery). Overall survival (OS) was estimated using the mortality database (Veritas Data Research, Fact of Death Mortality Data Index). **Results:** Among 8,456 CRC cases with available molecular data, CMS distribution was 10% CMS1, 26% CMS2, 12% CMS3, 22% CMS4, and 29% inconclusive. While canonical anatomic patterns were recapitulated (CMS1 right-sided, CMS2 left-sided, CMS3 rectal), CMS4 tumors were enriched in advanced-stage disease. CMS1 demonstrated high MSI-H prevalence (53%), frequent BRAF V600E (35%) and KMT2D (44%) alterations, and enrichment of MMR deficiency and APOBEC and POLE mutational signatures. CMS2 tumors were almost exclusively microsatellite stable (99.7%) and enriched for APC (84%) and TP53 (80%) mutations, whereas CMS3 showed intermediate MSI-H prevalence (10%) with frequent APC (74%) and KRAS (61%) alterations. CMS4 tumors exhibited low MSI-H prevalence (2%) but frequent TP53 (60%) and APC (59%) mutations. Among patients with stage II–III CRC, ctDNA positivity during the early post-operative MRD window was not associated with CMS subtype. In contrast, during later surveillance, ctDNA positivity was more frequent in CMS4 tumors compared with CMS1–CMS2 (36.8% vs 28.1%). Among MRD-positives, CMS1 was associated with the shortest OS, whereas CMS2 demonstrated the longest OS. No difference in OS was noted in MRD-negative patients. **Conclusions:** In this large real-world cohort, CMS subtypes were recapitulated with expected clinicogenomic and mutational associations and demonstrated distinct ctDNA detection patterns during surveillance. Integration of CMS biology, mutational features, and longitudinal ctDNA dynamics provides insights into residual disease and recurrence risk beyond static tissue-based classification. Safety and efficacy of neoadjuvant chemotherapy (NAC) in older patients with locally advanced colon cancer (LACC): Results from FOxTROT 1 and the FOxTROT 2 safety cohort population. First Author: Janet Shirley Graham, Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom

Background: The FOxTROT1 (FT1; NCT00647530) trial demonstrated feasibility and efficacy of six weeks of NAC for LACC compared with upfront surgery. The currently recruiting FOxTROT2 trial (ISRCTN83842641) is testing this approach in older or frail patients. Outcomes in older patients with LACC are inferior; therefore, new treatment strategies are required. Here in these trials we analyse the safety and efficacy of NAC in this group and report the DFS in the older subgroup of FT1 PMMR patients. **Methods:** Data from FT1 and the planned FT2 safety pilot (n=150) were combined and analysed by treatment arm and by age category (</> 70). Pre-specified endpoints included NAC delivery and perioperative complication rates for FT1 and FT2; DFS and pathological response are reported for FT1 patients by MMR status. We will update safety data for this presentation. **Results:** In FT1 292/1052 (27.8%) of patients were aged over 70; the median age of FT2 safety cohort was 76 (range 70-85). There were no significant differences by age in NAC delivery or in rates of peri-operative complications. For patients over 70, combining FT1&2 data, exploring those who received NAC, 88.5% completed the course as planned and 37.7% received an upfront or subsequent dose modification. Rates of peri-operative complications combining FT1&2 were similar between patients receiving NAC or upfront surgery: anastomotic leak (3.4% vs 3.3%), complication requiring hospital stay (FT1 9.3% vs 14.6%) or further surgery (2.6% vs 5.0%), and post-operative death (0.9 % vs 1.7%). For patients over 70 in FT1 16.4% were dMMR and 83.6% were pMMR. In pMMR patients overall NAC improved 3-year DFS (81.2% vs 75.4% without a DFS event; HR 0.70[0.52–0.94],p=0.02) compared with upfront surgery; results were consistent in older patients (81.2% vs 71.4%; HR 0.59[0.35-1.02],p=0.06). **Conclusions:** NAC is safe and well-tolerated in older adults, with no increase in perioperative morbidity and preserved treatment delivery compared to rates in younger patients and when compared with upfront surgery. Promising efficacy in terms of 3-year DFS and pathological response were observed in older patients with pMMR tumors, consistent to those seen in younger patients. These data support the use of NAC in older patients with LACC and continued recruitment to FT2 to evaluate the long term impact. Clinical trial information: NCT00647530. Research Sponsor: None.

Organ preservation and local excision for rectal cancer: Long-term oncologic outcomes. First Author: Avihai Moscovici, Lankenau Medical Center, Wynnewood, PA

Background: Organ preservation is a desired outcome for rectal cancer patients after neoadjuvant chemoradiotherapy. In patients where a complete response is in question, endoscopically assisted full-thickness local excision offers a great option. Long-term data with this approach is limited. We report our experience with transanal endoscopic microsurgery (TEM) status post chemotherapy. **Methods:** Between January 2005 and October 2019, from a prospectively maintained rectal cancer database, we identified all patients who underwent TEM for adenocarcinoma after neoadjuvant CRT. Demographic data as well as follow-up interval and oncologic outcomes were reviewed and analyzed. **Results:** Ninety-two patients who underwent TEM for rectal cancer were included. The mean age was 67 years (32–94), 66% were male, and the mean BMI was 29.3 kg/m² (19.1–43). ASA classifications were II in 38%, III in 51%, and IV in 5% of patients. The mean tumor size was 3.1 cm (1–6) and mean estimated blood loss (EBL) was 29 mL (0–500). Postoperative 30-day morbidity occurred in 6.5% of patients, with no mortalities. The mean follow-up was 57.5 months (0.4-194.5), during which 7.6% of patients developed local recurrence and 6.5% developed systemic metastases. Based on final pathology, 48 patients with a complete pathologic response (ypT0) had local recurrence and distant metastasis rates of 4% and 2%, respectively. In patients with stage I disease (n=35), local recurrence occurred in 11% and distant metastasis occurred in 9%. Stage II patients (n=7) experienced a 14% rate of local recurrence with no distant metastases. Among stage III patients (n=2), both local and distant failure occurred in 50% of cases. **Conclusions:** TEM after neoadjuvant CRT was associated with excellent oncologic outcomes in patients achieving complete pathologic response. Selected patients with favorable residual disease experienced acceptable recurrence rates, supporting TEM as a potential organ-preserving strategy in this subgroup. In contrast, higher pathologic stage was associated with substantially increased local and distant failure, highlighting the need for strict selection, pathology-driven decision-making, and close surveillance. Research Sponsor: None.

Screening and trends: A Global Burden of Disease 2023 assessment of colorectal cancer mortality across G7 nations. First Author: Rana Uzair Ahmad, Trinity Health Livonia Hospital, Livonia, MI

Background: Historically, the adoption of screening techniques has led to a steady decline in colorectal carcinoma (CRC) mortality in high-income countries. However, recent epidemiological data points towards a potential saturation of screening benefits and a rising burden of early-onset disease. Using Global Burden of Disease (GBD) 2023 data, we were able to identify points of stagnation and trend reversals in CRC mortality rates for G7 nations and hypothesize a systemic screening saturation in the post-pandemic era. **Methods:** The Global Burden of Disease 2023 study was used to retrieve data that included age-standardized death rates (ASDR) for G7 nations (2000-2023). Trends were analyzed using the Joinpoint regression Program, Version 5.4.0.0. We employed a log-linear model to estimate Annual Percent Change (APC). Pairwise comparison tests assessed parallelism between national trajectories to identify statistically distinct trend patterns. **Results:** From 2000 to 2023, epidemiological data shows an overall decline in the age standardized death rates (ASDR) for colorectal carcinoma in the USA. The ASDR in 2000 was 18.54 (95% UI: 16.80-19.87) and in 2023 it decreased to 12.64 (AAPC: -1.66: 95% CI: -1.83 to -1.49). Upon further analysis, three individual trajectory phenotypes were detected across the G7. The USA and Canada displayed a stagnation phenotype, in which mortality rates plateaued in the more modern years after initial rapid declines. In USA 2018-2023 APC was -0.48 (95% CI: -1.03 to 0.08) and in Canada 2020-2023 APC was 0.26 (95% CI: -0.94 to 1.47). The UK, Japan and France exhibited a rather alarming reversal phenotype, where mortality rates significantly accelerated in recent years. In UK 2021-2023 APC was 2.87 (95% CI: 0.74 to 5.06) while Japan 2021-2023 APC was 2.68 (95% CI: 1.45 to 3.93) and France 2021-2023 APC was 2.56 (95% CI: -2.06 to 7.40). Italy, however, has maintained a sustained decline phenotype, which sharply contrasts with that of the aforementioned nations. In Italy 2003-2023 APC was -1.65 (95% CI: -1.74 to -1.56) with no evidence of saturation. Pairwise comparison confirmed that the USA trajectory was significantly non-parallel to Italy ($p < 0.05$). **Conclusions:** For the majority of G7 nations, the era of universal CRC mortality decline has come to an end. While the USA and Canada show halted progress, the UK, Japan and France show early signs of slope inversion. On the contrary, Italy's clear lead in maintenance of declining mortality suggests a policy-based limitation as opposed to unavoidable biological circumstances. Urgent implementation of revolutionized screening techniques and interventions, focusing on hard-to screen populations as well as early onset cohorts, are required to avert a global deterioration in CRC outcomes. Association of *FBXW7* mutation with prolonged survival in microsatellite instability–high colorectal cancer treated with immune checkpoint blockade. First Author: Margaret R. Pruitt, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Colorectal cancer (CRC) remains a major cause of cancer-related mortality. Biomarkers of response to novel therapies may improve treatment selection and outcomes. Microsatellite instability (MSI-H) is a predictor of response to immune checkpoint blockade (ICI); however, less than half of patients with MSI-H CRC have a durable response to ICI. *FBXW7* mutations (MT) are common in CRC but their prognostic significance in patients treated with ICI is not well studied. Here, we characterized *FBXW7*-MT in CRC and their association with ICI outcomes. **Methods:** A total of 29,446 CRC (MSS, n = 27,323; MSI-H, n = 2,123) samples were tested by next generation sequencing (592, NextSeq; WES, NovaSeq) and WTS (NovaSeq; Caris Life Sciences, Phoenix, AZ). TMB was assessed by non-synonymous mutations/Mb (high ≥10). Immune cell proportions were estimated using WTS deconvolution (Quantiseq). Real-world median overall survival (mOS) data were derived from insurance claims, calculated from tissue collection or treatment (chemotherapy: CAPEOX, Capecitabine, FOLFIRI, FOLFIRINOX, Fluorouracil, Irinotecan, Oxaliplatin; ICI: Nivolumab, Pembrolizumab) initiation to last contact, and analyzed using Kaplan-Meier. Statistical significance was assessed by chi-square and Mann-Whitney U test with p-values adjusted for multiple comparisons ($q<0.05$). **Results:** *FBXW7*-MT was enriched in MSI-H (29.6% (n=608) vs 9.2% (n=3,025), $p<0.05$) compared to MSS tumors. Among MSI-H tumors, *FBXW7*-MT had higher median TMB (40 vs 37, $q<0.05$) and numerically higher TMB-high frequency (99.2% vs 97.9%, p=0.05) compared to *FBXW7*-WT. Analysis of inferred immune cells revealed that *FBXW7*-MT MSI-H CRC had lower median cell fraction (%) of M2 macrophages (2% vs 2.5%) compared to *FBXW7*-WT. In MSI-H CRC, *FBXW7*-MT patients had better mOS when treated with ICI (48.3 vs 34.2 months, HR 0.68, 95% CI 0.52 – 0.9, p=0.006) compared to *FBXW7*-WT, whereas there was no difference in mOS in MSI-H CRC treated with chemotherapy (HR 0.95, p = 0.67) compared to *FBXW7*-WT. *FBXW7*-MT was not associated with OS in MSS CRC. In MSI-H CRC, *R465C/H/L/S* (20.6%), *R505C/H/L/G* (7%) and *R479Q/G* (3.4%) were the most common *FBXW7* hotspot mutations. *R465C/H/L/S* had better mOS with ICI (HR 0.61, p=0.04) compared to *FBXW7*-WT. Multivariable Cox analysis adjusted for TMB and PD-L1 showed *FBXW7*-MT is an independent predictor of improved OS with ICI in MSI-H CRC (HR 0.69, 95% CI 0.53 – 0.9, p=0.007). **Conclusions:** This large study is the first to report a positive association with *FBXW7* mutation and OS in MSI-H CRC treated with PD1/PD-L1 blockade. While requiring validation in independent cohorts, our findings suggest that *FBXW7*-MT is a biomarker of response to ICI and that targeting *FBXW7* may be an effective way of augmenting the clinical activity of ICI in MSI-H CRC. Clinicopathologic features of South African colorectal cancer patients by HIV status in a retrospective cohort study. First Author: Jacob Lee Dubner, Columbia University Medical Center, New York, NY

Background: Colorectal cancer (CRC) is increasing among people living with HIV. South Africa (SA) has the largest HIV-infected population in the world. Data characterizing the features of CRC among HIV patients in SA is limited. We compared the clinicopathologic features of CRC patients in SA by HIV-status. **Methods:** A retrospective cohort of CRC patients was identified using a database of histologically confirmed CRC patients seen at one of four referral hospitals in KwaZulu-Natal, SA between 2000 and 2024. Confirmed HIV-positive patients were randomly matched (1:2) with patients without HIV based on age at CRC diagnosis, year of CRC diagnosis, race, and tumor location. Additional clinical data was extracted through retrospective review of medical records. Chi-squared tests were used to compare features by HIV-status. **Results:** We identified 106 CRC patients with confirmed HIV-positive status and matched them with 155 CRC patients with confirmed HIV-negative status and 57 CRC patients with unknown HIV-status (assumed to be HIV-negative for analysis). At the time of CRC diagnosis, HIV-positive patients had an average duration of infection of 5.2 years and a mean baseline CD4 count of 451 cells/mm^3. 72.6% of HIV patients were on antiretroviral therapy. HIV-status was not associated with duration of symptoms prior to CRC diagnosis (cohort mean 9.6 months; p-value = 0.687). HIV-positive patients were more likely than HIV-negative patients to present with metastatic disease (40.6% vs 28.8%, p-value = 0.035) and to have poorly differentiated tumors (13.9% vs 4.5%, p-value = 0.011). HIV-status was not associated with the rate of curative-intent treatment initiation (62.1% of non-metastatic patients received stage-appropriate treatment; p-value = 0.199) or palliative-intent systemic therapy (81.7% of metastatic patients received systemic therapy; p-value = 0.105). **Conclusions:** In SA, CRC patients with HIV are more likely than patients without HIV to present with high grade tumors and metastatic disease. This suggests a more aggressive tumor biology in this population. A comparison of overall survival by HIV-status will be presented at ASCO 2026. Future studies will compare the CRC tumor microenvironment by HIV-status in a subset of patients. Research Sponsor: National Cancer Institute; 3K12CA279872-02S1.

Evaluation of circulating tumor DNA (ctDNA) burden, detected mutations, and clinical outcomes in metastatic colorectal cancer (mCRC) using real-world data (RWD). First Author: Alicia Catania McDonald, Merck & Co., Inc., Rahway, NJ

Background: ctDNA is a promising prognostic biomarker in colorectal cancer; however, there is limited RWD on its prognostic value in mCRC. We leveraged RWD to assess pre-treatment (Tx) ctDNA burden and gene mutations, and evaluated the association between ctDNA burden and clinical outcomes in patients (pts) with mCRC. **Methods:** Pts with mCRC identified in the GuardantINFORM database who underwent Guardant 360 comprehensive genomic profiling between June 1, 2014 to June 30, 2023 were included. First metastatic diagnosis date was used as the index date. ctDNA burden (% max variant allele fraction ctDNA levels) was categorized as below limit of detection (no ctDNA), ≤ median value (low ctDNA), and > median value (high ctDNA). ctDNA burden and gene mutations/alterations detected prior to 1L systemic therapy were summarized. Associations with OS, time to next Tx (TTNT), and time to Tx discontinuation (TTD) were assessed using Cox proportional hazards models for the overall cohort and by microsatellite instability (MSI) status, stratified by 1L and 2L Tx. **Results:** There were 3273 pts with mCRC included (non-MSI-high [H], n = 2750; MSI-H, n = 100; missing, n = 423). Mean ctDNA burden was 19.9% overall, 20.7% in non-MSI-H, and 14.6% in MSI-H cohorts. Top 3 gene mutations were *TP53* (65.8% and 67.2%), *APC* (59.7% and 60.7%), and *KRAS* (40.6% and 41.2%) in the overall and non-MSI-H cohorts; and, *ARIDIA* (71.0%), *TP53* (67.0%), and *APC* (65.0%) in the MSI-H cohort. Top 3 specific variants were *EGFR* AMP (23.7% and 25.3%), *KRAS* G12D (11.3% and 11.4%), and *KRAS* G12V (8.2% and 8.5%) in the overall and non-MSI-H cohorts; and *BRAF V600E* (39.0%), *ARIDIA D1850fs* (22.0%), and *PIK3CA H1047R* (21.0%) in the MSI-H cohort. In the overall cohort, high ctDNA compared to low ctDNA was statistically significantly associated with shorter OS (HR [95% CI]: 1L, 1.63 [1.43-1.87]; 2L, 1.42 [1.19-1.70]) and TTNT (1L, 1.43 [1.27-1.60]; 2L, 1.39 [1.19-1.63]) after adjusting for confounders. Conversely, no ctDNA compared to low ctDNA was statistically significantly associated with longer OS (0.70 [0.53-0.91]) and TTNT (0.75 [0.58-0.97]) in the 1L setting after adjusting for confounders; these associations were also observed when stratified by MSI status. ctDNA burden was not statistically significantly associated with TTD in 1L regardless of MSI status. In 2L, high ctDNA was associated with shorter TTD compared to low ctDNA overall (1.19 [1.05-1.34]), with similar findings in the non-MSI-H cohort. **Conclusions:** High ctDNA burden prior to 1L and 2L therapy was associated with shorter OS and TTNT, suggesting a higher disease burden or more aggressive disease. The absence of detectable ctDNA was associated with improved survival and may identify pts with better prognosis or slower-growing tumors. These findings provide growing evidence for ctDNA as a potential prognostic biomarker in mCRC. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Epidemiology of early-onset colorectal cancer in the WHO Eastern Mediterranean Region: Regional and global comparisons. First Author: Fares A. Qtaishat, The University of Jordan, School of Medicine, Amman, Jordan

Background: Early onset colorectal cancer (EO-CRC) is increasing globally, yet studies from the WHO Eastern Mediterranean Region (EMRO) are limited. We quantified the burden, temporal trends, and future projections of EO-CRC in EMRO and compared patterns with regional and global estimates. **Methods:** We conducted a population based study using GLOBOCAN 2022 data. EO-CRC outcomes included age-standardized incidence rates (ASIRs), age-standardized mortality rates (ASMRs), and 1-, 3-, and 5-year prevalence per 100000 population. Age-specific analyses were conducted. Temporal trends were assessed using Estimated Annual Percentage Change (EAPC). Associations between Human Development Index (HDI) and EO-CRC outcomes were evaluated using Pearson correlation coefficients (r). **Results:** In 2022, EMRO recorded 53941 new CRC cases (ASIR = 8.9), including 15381 EO-CRC cases (ASIR = 2.5), and 29918 CRC deaths (ASMR = 5.1), including 6965 EO-CRC deaths (ASMR = 1.1). EO-CRC incidence was lowest among individuals aged 0–19 years (ASIR = 0.17), increased in those aged 20–34 years (ASIR = 1.9), and peaked among adults aged 35–49 years (ASIR = 8.4), who accounted for most EO-CRC cases and deaths. Marked inter-country heterogeneity was observed. Jordan had the highest EO-CRC incidence (ASIR = 4.2), followed by Libya (ASIR = 3.5) and Iran (ASIR = 3.3), while EO-CRC mortality was highest in Jordan (ASMR = 1.9), followed by Oman and Somalia (ASMR = 1.8 each). Five-year EO-CRC prevalence was highest in Saudi Arabia (14.7 per 100,000), Oman (13.5), and Iran (13.3), but remained below 3 per 100000 in Afghanistan and Somalia. Males exhibited higher EO-CRC incidence (ASIR = 2.6) and mortality (ASMR = 1.2) than females (ASIR = 2.4; ASMR = 1.1), although several countries demonstrated a higher female burden. Compared with other WHO regions, EMRO demonstrated one of the highest EO-CRC mortality rates globally (ASMR = 1.1), exceeding Europe (ASMR = 1.0), South-East Asia (ASMR = 0.68), and the Western Pacific (ASMR = 0.98), despite having lower overall CRC incidence. Temporal trend analyses revealed concerning increases in EO-CRC incidence, with significant rises in Israel (EAPC = +2.58%). EO-CRC mortality was inversely correlated with HDI ($r = -0.45$; $p = 0.034$), indicating a disproportionate mortality burden in lower HDI countries. Projections indicate that annual EO-CRC cases will increase from 15381 in 2022 to 24396 by 2050, and annual deaths from 6965 to 11005, underscoring a rapidly escalating regional burden. Incidence and mortality are projected to rise faster in females across EMRO by 2050. **Conclusions:** EO-CRC is a rapidly growing, inequitable burden in EMRO, with high mortality and marked inter-country differences. Its disproportionate impact on lower HDI countries and younger populations highlights the urgent need for targeted interventions, including early detection and awareness campaigns. Impact of concomitant GLP-1 receptor agonist use on overall survival and chemotherapy-related adverse events in colorectal cancer: A real-world pharmacoepidemiologic cohort study. First Author: Arunkumar Krishnan, Atrium Health Levine Cancer, Charlotte, NC

Background: Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) are increasingly prescribed for diabetes and obesity and exert pleiotropic metabolic and anti-inflammatory effects. While prior studies have focused on their role in cancer prevention, limited data exist regarding their impact on cancer treatment outcomes. We evaluated the association between concomitant GLP-1 RA use and overall survival (OS) in patients with colorectal cancer (CRC) receiving standard first-line chemotherapy. **Methods:** Using the Blue Diamond Global Collaborative Network, adult patients with CRC initiating first-line FOLFOX or FOLFIRI between 2015 and 2024 were identified. Patients were classified as GLP-1 RA users if they received a GLP-1 RA (e.g., semaglutide, liraglutide, dulaglutide) within 90 days before or after chemotherapy initiation, and non-users otherwise. Cohorts were 1:1 propensity score matched for age, sex, BMI, diabetes status, line of therapy, comorbidities, and baseline corticosteroid use. The primary endpoint was OS. Kaplan–Meier methods and Cox proportional hazards models were used for analysis. **Results:** After matching, 4,824 patients were included (2,412 per cohort). Baseline characteristics were well balanced (mean age 61.8 years; 46% female; mean BMI 31.2 kg/m²; 58% with diabetes). At a median follow-up of 24.6 months, patients receiving concomitant GLP-1 RAs demonstrated significantly improved overall survival compared with non-users. Median OS was 28.4 months among GLP-1 RA users versus 23.6 months among non-users (log-rank $p<0.001$). GLP-1 RA use was independently associated with improved OS (HR 0.82, 95% CI 0.76–0.89). Regarding safety outcomes, GLP-1 RA users experienced a lower incidence of neutropenia (18.9% vs 23.7%; RR 0.80, $p=0.002$) and reduced chemotherapy-induced neuropathy (14.2% vs 18.6%; RR 0.76, $p=0.004$). Subgroup analyses demonstrated consistent OS benefit across chemotherapy backbone: FOLFOX (HR 0.81) and FOLFIRI (HR 0.84), and the most pronounced effect in patients with BMI ≥30 kg/m². Sensitivity analyses restricting sustained GLP-1 RA exposure (>6 months) yielded similar results. **Conclusions:** In this large real-world cohort of patients with colorectal cancer, concomitant GLP-1 receptor agonist use was associated with improved overall survival and reduced chemotherapy-related toxicity. These findings suggest a potential adjunctive therapeutic role for GLP-1 RAs during active cancer treatment, potentially mediated through metabolic stabilization, reduced systemic inflammation, and improved treatment tolerance. Prospective studies are warranted to confirm these observations. Research Sponsor: None.

Impact of social determinants of health on women with early-onset colorectal cancer: A retrospective study. First Author: Elaine Ognjanovski, Henry Ford Warren, Warren, MI

Background: The incidence of early-onset colorectal cancer (EOCRC) in adults under age 50 has significantly increased. Women with EOCRC often present with nonspecific gastrointestinal symptoms, leading to delayed diagnosis and care. The impact of social determinants of health (SDOH), such as insurance status, income, and race, on cancer outcomes, disease presentation and hospitalization severity in young women with EOCRC is not well known. This study investigates how SDOH factors are associated with stage at presentation, emergency admission, metastatic burden and inpatient outcomes in women hospitalized with EOCRC. **Methods:** We conducted a retrospective cohort study using the National Inpatient Sample (2018-2021) with hospitalized women aged 18–49 years, diagnosed with colorectal cancer, identified using ICD-10. SDOH variables included primary payer (private, Medicare, Medicaid, uninsured), ZIP-code median income, race, age and year of hospitalization. Primary outcomes included advanced stage at presentation, emergency admission, visceral metastatic involvement, disseminated metastasis, inpatient mortality, discharge disposition and length of stay (LOS). Survey-weighted multivariable logistic regression and linear regression models were performed, adjusting for age, race, insurance status and income quartile. **Results:** The most consistent predictors of delayed presentation and increased hospitalization severity were insurance status and race. Compared to private insurance, women with Medicare and Medicaid were 67% and 32% more likely to present with advanced stage ($p<0.001$), and over 3-fold and 2.5-fold more likely to present emergently ($p<0.001$). They were also significantly more likely to have visceral metastasis ($p<0.001$), have increased severity of illness ($p\leq0.023$), require non-home discharge ($p<0.001$), and require longer LOS (+0.8-0.9 days, $p<0.001$). Medicare was associated with higher inpatient mortality ($p=0.005$). Black race was independently associated with advanced stage, emergency presentation, visceral metastasis, inpatient mortality (all $p<0.001$), and longer LOS (+0.79 days, $p<0.001$). Younger age was associated with advanced stage and visceral metastasis ($p<0.001$). Higher ZIP-code income quartiles were associated with lower odds of emergency presentation ($p<0.001$), but not improved inpatient outcomes. Year of diagnosis was not significant across models. **Conclusions:** Among young women hospitalized with colorectal cancer, insurance status and race were strongly associated with advanced disease, emergency presentation, metastatic burden and greater hospitalization severity, independent of ZIP-code income. These disparities did not show improvement over time, highlighting system-level barriers. Targeted strategies to improve access and earlier recognition in high-risk populations of young women is required to improve oncologic outcomes. Research Sponsor: None.

Shifting dietary drivers of colorectal cancer mortality in the United States: A 33-year Global Burden of Disease analysis. First Author: Jennifer Kate Beckerman, George Washington University School of Medicine and Health Sciences, Washington, DC

Background: Early-onset colorectal cancer (EOCRC; ages 15–49 years) mortality is increasing in the United States. However, temporal changes in diet-attributable risk factors contributing to EOCRC mortality remain poorly characterized. Using three decades of Global Burden of Disease (GBD) data, we examined shifts in dietary risk factors contributing to EOCRC mortality to identify emerging targets for primary prevention. **Methods:** We conducted a retrospective population-based analysis of U.S. estimates from the GBD 2023 study (1990–2023). Age-standardized death rates (ASDR), years of life lost (YLLs), and disability-adjusted life years (DALYs) attributable to major dietary risk factors (high processed meat, high red meat, low whole grain, low fiber, low calcium, and low milk intake) were assessed among EOCRC. Period-specific percent changes (1990–1999, 2000–2009, 2010–2019, 2020–2023), rank-order transitions, and sex-stratified patterns were examined. All estimates were derived using GBD cause-of-death ensemble modeling and include 95% uncertainty intervals. **Results:** In 1990, low whole grain intake was the leading diet-attributable risk factor for ASDR (0.44 per 100,000), followed by red meat (0.40) and processed meat (0.34). Although dietary inadequacy–related risks increased early (low whole grain DALYs +338.9% and YLLs +311.1% in 1990–1999), these burdens declined substantially after 2000. In contrast, processed meat consumption demonstrated persistent and increasingly dominant associations with mortality, with DALYs rising by +430.8%, +223.1%, +94.8%, and +15.9% across successive periods. By 2023, processed meat accounted for the highest ASDR (0.55), surpassing low whole grain (0.53) and red meat (0.49). Sex-stratified analyses showed processed meat emerged as the leading diet-attributable risk among males by 2010 and rose from third to second among females, narrowing the gap with low whole grain intake. **Conclusions:** Over 33 years, diet-attributable EOCRC mortality in the US has undergone a rank-order transition from dietary inadequacy toward processed meat consumption, particularly among males and increasingly among females. The persistence and dominance of processed meat-attributable burden highlight a critical, modifiable lifestyle risk factor and underscore an urgent opportunity for targeted, age- and sex-specific primary prevention strategies aligned with colorectal cancer prevention recommendations. Research Sponsor: None.

Age-standardized early-onset colorectal cancer death rates (per 100,000 population) attributable to dietary risk factors in the United States, 1990–2023.

	1990	2000	2010	2020	2023
Red Meat	0.40	0.48	0.47	0.50	0.49
Processed Meat	0.34	0.46	0.50	0.55	0.55

Association of pre-diagnosis primary care utilization with metastatic disease, treatment adherence, and mortality in colorectal cancer. First Author: Hieu Nguyen, Department of Radiation Medicine and Applied Sciences, University of California, San Diego, La Jolla, CA

Background: In addition to timely evaluation and screening in patients with colorectal cancer (CRC), routine primary care provider (PCP) engagement may improve CRC survival outcomes through earlier diagnosis and increased treatment adherence. We evaluated the association between pre-diagnostic PCP utilization and metastatic disease at diagnosis, cancer-specific mortality (CSM), and cancer treatment adherence. **Methods:** Using the Surveillance, Epidemiology, and End Results (SEER)-Medicare database, we conducted a retrospective cohort study of adults aged 68-75 diagnosed with CRC between 2010-2017. PCP visits in the three years preceding diagnosis were categorized as none (0 visits), occasional (1–2), or annual (3). Multivariable logistic regression models evaluated associations between PCP use and metastatic CRC at diagnosis, as well as treatment adherence. Locally advanced (Stage III) treatment adherence was defined as curative therapy ≤1 year from diagnosis, and metastatic treatment adherence was defined as systemic therapy ≤6 months from diagnosis. A competing risk Cox proportional hazards model evaluated cancer-specific mortality (CSM), with non-cancer death as a competing event. **Results:** Of 18,604 patients with CRC, 12.9% had no prior PCP visits, 48.6% had occasional visits, and 38.5% had annual visits. Compared to patients with no pre-diagnostic PCP use, occasional and annual PCP visits were respectively associated with 43% and 57% lower odds ($p < 0.001$) of metastatic disease at diagnosis and 48% and 57% lower odds ($p < 0.001$) of CSM (Table 1). Among patients with locally advanced CRC, occasional and annual PCP use were associated with 64% and 150% higher odds of receiving curative treatment, respectively (Table 1). Similarly, occasional and annual PCP use in patients with metastatic CRC were associated with 2-fold and 3-fold higher odds, respectively, of receiving systemic treatment (Table 1). **Conclusions:** Primary care utilization prior to CRC diagnosis is significantly associated with lower odds of metastatic disease, lower risk of CSM, and higher odds of treatment adherence, with the highest effects observed with annual PCP utilization. Increasing PCP engagement is an essential strategy to improving outcomes in patients with CRC. Research Sponsor: None.

Multivariate estimates for the effect of pre-diagnostic primary care provider (PCP) utilization prior to cancer diagnosis.

	Metastatic Disease at Diagnosis OR, [95% CI], p-value	Cancer-Specific Mortality sHR, [95% CI], p-value	Received Treatment (Locally advanced CRC) OR, [95% CI], p-value	Received Treatment (Metastatic CRC) OR, [95% CI], p-value
1-2 PCP visits (Occasional)	0.57 [0.51-0.64], p < 0.001	0.52 [0.48-0.56], p < 0.001	2.64 [2.10-3.30], p < 0.001	2.08 [1.70-2.56], p < 0.001

Bowel function after sphincter-preserving treatment with neoadjuvant therapy for low rectal cancer. First Author: Yuanshan Chen, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China

Background: Neoadjuvant therapy (NAT) is important for locally advanced rectal cancer, including neoadjuvant chemoradiotherapy (nCRT) and neoadjuvant chemotherapy alone (nCT). Based on the tumor response, sphincter-preserving treatment such as low anterior resection (LAR) or watch and wait (WW) strategy can be implemented. The effects of these therapy combinations on functional outcomes for low rectal cancer remain unclear. **Methods:** We conducted a retrospective study recruiting patients who were treated at The Sixth Affiliated Hospital of Sun Yat-sen University between 2010 and 2023. Patients who underwent sphincter-preserving treatment after NAT for low rectal cancer with no distant metastasis were eligible. Low rectal cancer was defined as the tumor height no more than 5 cm from the anal verge. Patients with multiple primary carcinoma or familial adenomatous polyposis were excluded. The incidence of low anterior resection syndrome (LARS) was assessed using the LARS score. Oncological outcomes included overall survival (OS), disease-free survival (DFS), and stoma-free survival (SFS). Functional and oncological outcomes were evaluated based on Wilcoxon signed-rank test and Kaplan-Meier survival analysis. The difference of baseline characteristics in different treatment groups was analyzed using propensity scores with inverse probability treatment weighting (IPTW). **Results:** We enrolled 590 patients: 49 in nCRT+WW group, 181 in nCT+LAR group and 360 in nCRT+LAR group. Median follow-up was 3.4 years (IQR 2.8-4.4), 5 years (IQR 4.3-7.1) and 7.3 years (IQR 4.8-9.3), respectively. After IPTW, all baseline characteristics were similar in the three groups. 3-year OS was 91.0% (95% CI 81.6-100.0) for nCRT+WW group, 89.3% (84.5-94.5) for nCT+LAR group, 93.2% (90.7-95.7) for nCRT+LAR group. 3-year DFS was 62.5% (95% CI 45.6-85.7), 71.0% (64.1-78.6) and 77.5% (77.3-81.9), respectively. There was no differences in oncological outcomes. The incidence of major LARS in the three groups was 0% (0/18.6), 34.1% (35.2/103.2) and 45.9% (104.2/226.8). 3-year SFS without IPTW was 95.2% (20/21) for nCRT+WW, 91.0% (152/167) for nCT+LAR, and 79.7% (244/306) for nCRT+LAR. **Conclusions:** This retrospective study shows similar oncological outcomes in the three sphincter-preserving strategies for low rectal cancer, while nCRT+WW presented with superior bowel function. Functional outcomes are inversely correlated to the intensity of local therapy. Research Sponsor: None.

Outcomes for the three therapy combinations after IPTW.

	nCRT+WW	nCT+LAR	nCRT+LAR
Tumor Height, cm	2.71 (1.20)	3.74 (0.83)	3.60 (0.91)
Clinical Stage III, %	75.4	69.1	70.3
3-year OS, %	91.0	89.3	93.2
3-year DFS, %	62.5	71.0	77.5
Major LARS, %	0	34.1	45.9
Minor LARS, %	22.5	22.9	24.1
None LARS, %	77.5	43.0	30.0
3-year SFS*, %	95.2	91.0	79.7

*Without IPTW.

Genomic profiling to define molecular drivers of colorectal neuroendocrine carcinoma subtypes. First Author: Jenny Xue, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Neuroendocrine carcinoma (NEC) is a rare and aggressive subtype of colorectal cancer (CRC), often arising in association with poorly differentiated adenocarcinoma. Two histologic subtypes, small cell NEC (SCNEC), and large cell NEC (LCNEC), have been described; however, how these subtypes differ, and whether they share molecular origins with the adenocarcinoma component in mixed adenocarcinoma and neuroendocrine carcinoma (MANEC) tumors, remain unclear. Better characterization of the genomic alterations driving NECs is needed to clarify disease biology and improve outcomes. **Methods:** We identified 125 patients with NEC of the colon and rectum who received care at Memorial Sloan Kettering Cancer Center. All patients underwent tumor profiling using the institutional targeted sequencing platform MSK-IMPACT. For 11 patients with MANEC, the adenocarcinoma and NEC components were sequenced separately. **Results:** Among 125 patients, 33 had SCNEC, 50 had LCNEC, and 42 had histologic features intermediate between SCNEC and LCNEC. 62% of patients presented with stage IV disease, and NEC was enriched at metastatic sites in MANEC cases. Clinical outcomes were poor across all groups, with a median survival of 11 months for stage IV patients (9.5m for SCNEC, 11m for LCNEC). SCNEC was more commonly observed in the rectum and genomically characterized by frequent *RB1* loss (70%), with a smaller subset harboring *PTEN* loss (24%). Notably, *TP53* mutations were identified in 58% of the cases, lower than the frequency observed in sporadic advanced CRC. In contrast, LCNEC was more often right sided, associated with an adenocarcinoma component and genomically enriched for *MYC* amplification (28%) and *BRAF* mutations (38%). We found that *MYC* amplification frequently occurred on extrachromosomal DNA, as confirmed by both FISH and shallow whole genome sequencing. Based on genomic alterations, 21of the 42 (50%) unclassified cases could be assigned a histologic subtype. A subset of NECs lacked known neuroendocrine associated genomic alterations and are being investigated further. In 11 MANEC cases with separately sequenced components, *RB1* loss and *MYC* amplification were restricted to the neuroendocrine component, supporting a causal role in neuroendocrine differentiation and clonal evolution from adenocarcinoma. Across the cohort, *PIK3CA* (6%) and *SMAD4* (9%) mutations were less frequent than expected and were absent in the NEC component of MANEC cases. DLL3 expression was evaluated in a small subset and was positive in some SCNECs but not in LCNEC. **Conclusions:** SCNEC and LCNEC represent clinically and genomically distinct subtypes of colorectal NEC. For NECs that cannot be classified based on histology alone, genomic profiling should be used to aid classification. Ongoing studies aim to validate our genomic findings above and to model the biology of NEC to identify more effective therapeutic strategies. Research Sponsor: U.S. National Institutes of Health; 5T32CA009207.

Defining prostaglandin-driven dysregulation in *PIK3CA*-mutant colorectal cancers: A real-world multi-omic analysis. First Author: Andrew M. Gaya, Cromwell Hospital, London, United Kingdom

Background: *PIK3CA* mutations occur in a meaningful subset of colorectal cancers (CRC) and have been associated with improved clinical outcomes in patients receiving aspirin and celecoxib. *PIK3CA* activation has been linked to upregulation of *PTGS2* and downstream prostaglandin E2 signaling, promoting tumor-associated inflammation, angiogenesis, and immune suppression. Aspirin-mediated inhibition of prostaglandin synthesis may therefore counteract this biology in *PIK3CA*-mutant CRC, although the underlying molecular mechanisms remain incompletely characterized. **Methods:** A total of 823 CRC tumor samples underwent DNA-based next-generation sequencing, with matched whole-transcriptome sequencing (20,802 genes) available for 263 tumors. *PIK3CA* mutation prevalence, hotspot distribution, and co-mutation patterns were evaluated. A predefined prostaglandin–inflammation gene signature (*PTGS2, PTGES, PLA2G4A, IL6, STAT3, PTGER4, VEGFA, IDO1*) was assessed ($\log_2$ fold change >2). Coordinated signature activation was quantified. **Results:** *PIK3CA* mutations were detected in 12.8% (105/823) of CRCs and were more frequent in right than left-sided tumors (15.2% vs 11.1%). Among *PIK3CA*-mutant tumors, 25.7% were *KRAS/NRAS/BRAF* wild type (WT), while *KRAS* co-mutation predominated (65.7%); *NRAS* and *BRAF* co-mutations were rare (1.9% and 5.7%), as summarized in the Table. *ERBB2* alterations were rare in *PIK3CA*-mutant tumors (4.8%) and in *KRAS/NRAS/BRAF*-mutant tumors (3.2%,), while they were enriched in the *KRAS/NRAS/BRAF* WT subgroup (8.9%). Among *PIK3CA*-mutant tumors, key prostaglandin biosynthesis genes *PTGS2, PTGES*, and *PLA2G4A* were overexpressed in 8.8% (3/34), while downstream inflammatory and immune-modulatory genes including *IL6, STAT3, IDO1*, and *CD274* were overexpressed in 11.8% (4/34). Prostaglandin–inflammation signature activation was more frequent in *KRAS* WT than *KRAS*-co-mutant *PIK3CA* tumors (57.1% [4/7] vs 51.9% [14/27]). Among microsatellite-stable (MSS) tumors, 47.6% (10/21) showed signature activation. Tumors with combined *PIK3CA* mutation and prostaglandin pathway activation showed enrichment of inflammatory, angiogenic, and epithelial–mesenchymal transition–related programs. **Conclusions:** *PIK3CA*-mutant CRC represents a biologically distinct subset characterized by coordinated activation of prostaglandin-driven inflammatory and immune-modulatory pathways. These features provide a mechanistic rationale for the reported aspirin benefit in *PIK3CA*-mutant CRC and support integrated genomic–transcriptomic profiling to guide biomarker-driven therapeutic strategies. Research Sponsor: None.

Prevalence of *PIK3CA* alterations and co-mutations in CRC.

Biomarkers	Prevalence (%; n=105)
***PIK3CA* mutation (overall)**	12.8 (105/823)

Divergent transcriptomic signatures and microenvironmental markers of *KRAS* and *BRAF* mutations in colorectal cancer: A multi-omics integrative analysis. First Author: Muzammil Shaikh, Nanavati Max Super Speciality Hospital, Mumbai, India

Background: *KRAS* and *BRAF* mutations are critical drivers in colorectal cancer (CRC), acting as key nodes in the MAPK signaling pathway. While their genomic prevalence is well-documented, the specific transcriptomic programs they trigger and how these programs differ between *KRAS* and *BRAF* variants remain a subject of intense translational interest. This study utilizes a multi-omics approach to define mutation-specific signatures that could inform personalized therapeutic strategies. **Methods:** We performed an integrated analysis of SNV/Indel data and gene expression profiles from 192 CRC patients. Patients were stratified into *BRAF*-mutant (n=20), *KRAS*-mutant (n=102), and MAPK-wild-type (WT, n=64) groups. Frequency was calculated as the percentage of unique samples mutated per gene. Differential expression analysis (DEA) was utilized to identify significant ($p < 0.05$) gene expression changes specific to each driver mutation. **Results:** The most frequently mutated genes were *TP53* (79.2%), *APC* (56.8%), and *KRAS* (53.1%). *BRAF* mutations were identified in 10.4% of the cohort. *KRAS*-mutant tumors exhibited a specific upregulation of *SPP1* (osteopontin) and *TGFBI*. These markers are associated with extracellular matrix remodeling and TGF-β signaling, suggesting that *KRAS* mutations may actively contribute to an immune-excluded tumor phenotype. *BRAF*-mutant CRC was characterized by a distinct signature involving *ABI3BP* upregulation and a profound downregulation of *CTNNBL1* ($p < 0.00001$). Additionally, a cluster of small nucleolar RNAs (*SNORA2B*, *SNORA9*) was significantly elevated, pointing toward altered ribosome biogenesis or non-coding RNA regulation unique to the *BRAF*-mutant subset. While both mutations activate the MAPK pathway, the downstream transcriptomic output is significantly divergent, with *KRAS* favoring myeloid-recruiting signals (*SPP1*) and *BRAF* favoring structural and RNA-processing alterations. **Conclusions:** Our multi-omics integration reveals that *KRAS* and *BRAF* mutations in CRC are not transcriptomically redundant. The discovery of *SPP1* as a *KRAS*-associated marker and *CTNNBL1* as a *BRAF*-linked marker provides novel avenues for targeted therapy and patient stratification. Specifically, *KRAS*-mutant patients might benefit from therapies targeting the *SPP1*-TGF-β axis in combination with standard care. Research Sponsor: None.

Development and validation of a National Database–derived nomogram for predicting postoperative survival in colorectal cancer. First Author: Mohyeddine El Sayed, Medical University of South Carolina, Charleston, SC

Background: Prognosis after curative-intent surgery for colorectal cancer remains heterogeneous and incompletely explained by TNM staging alone. Existing prognostic tools often exclude important demographic, clinical, and biologic factors. Improved risk stratification is needed to support individualized postoperative prognostication. **Methods:** Using the National Cancer Database (NCDB), data from 88,696 patients diagnosed between 2018–2019 were used to develop and internally validate five prognostic models. All models were extensions of the MSK colon cancer nomogram and were fit using the full cohort. The full model incorporated all MSK predictors plus additional demographic, tumor, and treatment variables including perineural invasion and microsatellite instability status. Reduced models included MSK predictors and select variable subsets. Cox proportional hazards regression was used to estimate 5-year (5y) overall survival. Calibration was assessed by comparing deciles of predicted vs observed 5y Kaplan–Meier survival probabilities (expected-to-observed (E/O) ratios). Discrimination was evaluated using 5y area under the time-dependent receiver operating characteristic curve (AUC). Bias-corrected calibration curves and AUCs were generated to assess model generalizability to external populations. Model performance was compared directly with the MSK nomogram by comparing 5y AUCs calculated using a random sample of 1,000 NCDB-cohort patients. Category-free net reclassification improvement (NRI) was also calculated for patients with known vital status at 5y. **Results:** Calibration and discrimination were similar across all models. In the full model, E/O ratios demonstrated excellent calibration, with median E/O = 1.01 (range = 0.82-1.08). Full model discrimination was excellent with 5y AUC = 0.787 (95% CI, 0.782–0.793). Bias-corrected calibration curves and AUCs indicated stable performance supporting generalizability. In our 1,000 patient random sample, the full model 5y AUC was 0.822 (95% CI, 0.779–0.866), compared with 0.799 (95% CI, 0.753–0.844) for the MSK nomogram, with no statistically significant difference (p = 0.13). In our 1,000 patient NCDB sample, 397 patients had known 5y vital status (258 deaths, 139 alive, 603 censored prior to 5y) with the full model showing improved overall, event and nonevent discrimination compared with the MSK nomogram (overall 5y NRI = 0.35, event NRI = 0.12, and nonevent NRI = 0.24). **Conclusions:** We developed a postoperative survival nomogram for colorectal cancer that demonstrated good calibration and discrimination and meaningfully improved risk classification compared with the MSK model. Integration of additional routinely available variables enables more individualized postoperative prognostication. Research Sponsor: None.

Molecular differences between early- and later-onset colorectal cancer in a Chilean cohort: A retrospective MSI and NGS-based analysis. First Author: Tamara Saumann, Facultad de Medicina Clinica Alemana Universidad del Desarrollo, Santiago, Chile

Background: The incidence of early-onset colorectal cancer (EOC) is increasing worldwide; however, molecular data from Latin American populations remain scarce. We compared molecular alterations, including microsatellite instability (MSI) status and selected next-generation sequencing (NGS)–derived gene alterations, between EOC and later-onset colorectal cancer (LOC) in a Chilean cohort. **Methods:** We conducted a retrospective analysis of patients diagnosed with colorectal cancer with MSI assessment and/or NGS testing available between March 2017 and September 2025 at a private hospital in Chile. MSI status was determined by immunohistochemistry and/or PCR. In-house NGS panels were analyzed. Clinical variables included age at diagnosis, sex, and tumor location. EOC was defined as diagnosis $<$50 years and LOC as $\geq$50 years. Molecular alterations were compared using Fisher exact test, reporting odds ratios (OR) with Benjamini–Hochberg false discovery rate (FDR) correction. **Results:** A total of 324 patients were included (EOC n=66; LOC n=258). Median age was 42.6 years in EOC and 66.5 years in LOC. Tumor sidedness was comparable between groups, with a predominance of left-sided tumors in both EOC (54.5%) and LOC (61.2%). MSI status was available in 310 patients; MSI-H prevalence was 10.8% in EOC and 15.1% in LOC (OR 0.68, 95% CI 0.29–1.59; p=0.43). NGS denominators varied by gene according to panel coverage. No individual gene showed statistically significant differences after FDR correction. Pathway-level trends were observed (Table 1). In the WNT pathway, APC alterations were more frequent in EOC (83.3% vs 52.2%; OR 4.60; p=0.059). In the MAPK pathway, KRAS alterations were numerically higher in LOC (55.2% vs 37.5%; OR 0.49; p=0.13), while BRAF alterations were more frequent in EOC (16.7% vs 8.3%; OR 2.20; p=0.29). In the PI3K pathway, PIK3CA (29.2% vs 15.6%; OR 2.22; p=0.12) and PTEN (8.3% vs 2.1%; OR 4.27; p=0.15) alterations trended higher in EOC. TP53 alterations were highly prevalent and similar across groups. **Conclusions:** In this Chilean cohort, EOC and LOC showed similar MSI prevalence and largely overlapping molecular profiles. Although no gene-level differences remained significant after multiple-testing correction, pathway-specific trends suggest increased WNT and PI3K alterations in EOC and higher MAPK signaling in LOC. These findings highlight the need for larger, uniformly sequenced studies in Latin American populations. Research Sponsor: None.

Selected pathway-specific molecular alterations.

Category	Gene	EOC n/N (%)	LOC n/N (%)	OR	p
WNT	APC	10/12 (83,3)	36/69 (52,2)	4,60	0,059
MAPK	KRAS	9/24 (37,5)	53/96 (55,2)	0,49	0,13
	BRAF	4/24 (16,7)	8/96 (8,3)	2,20	0,29
PI3K	PIK3CA	7/24 (29,2)	15/96 (15,6)	2,22	0,12
	PTEN	2/24 (8,3)	2/96 (2,1)	4,27	0,15
DDR	ATM	1/24 (4,2)	5/96 (5,2)	0,80	1,00
TGF-β	SMAD4	3/24 (12,5)	7/96 (7,3)	1,81	0,47

Use of KMT2 family mutations to define a distinct epithelial-high, stromal-depleted, and interferon-active gene expression state in colorectal cancer. First Author: Songwit Payapwattanawong, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The *KMT2A–D* (MLL1–4) family of H3K4 methyltransferases are critical epigenetic regulators of enhancer landscapes and cell identity. At least one of the genes is mutated in 20-25% of colorectal cancer. Their role in shaping the tumor microenvironment (TME) remains distinct from their established roles in leukemia, where they are better described. We tested whether *KMT2* mutations are associated with specific immune/stromal phenotypes that could inform therapeutic stratification. **Methods:** We analyzed a retrospective institutional CRC cohort using targeted NGS (n = 2,267; 565 *KMT2*-mutant [MUT], 1,702 wild-type [WT]) and a transcriptomic subset with matched RNA-seq (n = 353; 73 MUT, 280 WT) from primary and metastatic specimens. Differential expression (DESeq2) and pathway enrichment (Hallmark GSEA) compared MUT vs. WT, adjusting for batch and tissue site. VST-based module z-scores (cancer associated fibroblast [CAF]/stroma, epithelial, IFN response, cell-cycle) were computed. xCell, EPIC, CIBERSORTx, and ESTIMATE scores were analyzed by linear regression on z-scored outcomes (MUT vs WT) adjusted for batch and tissue site; Benjamini–Hochberg false discovery rate (FDR). β denotes the adjusted mean difference in standardized score (MUT–WT) in SD units. Overall survival was assessed by Cox proportional hazards models. **Results:** *KMT2*-MUT tumors demonstrate a unique tumor biology, with higher epithelial (β = 0.30, FDR = 0.011), IFN response (β = 0.24, FDR = 0.021), and cell-cycle (β = 0.24, FDR = 0.021) modules with lower CAF/stroma (β = $-$0.29, FDR = 0.011). Consistent with this, GSEA showed enrichment of IFN-α/γ and proliferation programs (MYC/E2F/G2M) and depletion of epithelial-mesenchymal transition (EMT), myogenesis, and apical junction pathways (FDR $<$ 0.05). TME composition tools demonstrated lower stromal content [lower CAFs (EPIC, β = $-$0.288, FDR = 0.102), lower fibroblasts/stroma scores (xCell, $\beta\approx-0.36/-0.35$, FDR = 0.079), and trend toward lower StromalScore (ESTIMATE, β = $-$0.24, FDR = 0.20)], and trends to higher Th2 (xCell, β = 0.40, FDR = 0.059) and NK cells (xCell, β = 0.38, FDR = 0.079). After adjusting for age, sex, ECOG performance status, primary tumor site, stage, RAS and *BRAF* mutation status, and MSI status, overall survival did not differ significantly between tumors with and without *KMT2* family mutations, although there was a trend toward improved outcomes (HR 0.85, 95% CI 0.70–1.00; p = 0.078). **Conclusions:** *KMT2* family mutations in CRC characterize a tumor subset with retained epithelial identity, active proliferation, and interferon signaling, but markedly reduced stromal infiltration and EMT programs. This distinct biology suggests *KMT2* loss may impede the acquisition of aggressive mesenchymal features, highlighting a potential biomarker for stromal-modulating or immune-based therapies. Research Sponsor: None.

TPS3672 **Poster Session**

Phase 2/3 trial of pumitamig (PD-L1 × VEGF-A bsAb) plus chemotherapy versus bevacizumab plus chemotherapy in previously untreated, unresectable, or metastatic colorectal cancer (ROSETTA CRC-203). First Author: Tiago Biachi de Castria, Moffitt Cancer Center, Tampa, FL

Background: Microsatellite-stable/mismatch repair-proficient metastatic colorectal cancer (mCRC) demonstrated limited benefit from immune checkpoint inhibition and is treated with first-line standard chemotherapy with/without biologic agents, such as anti-VEGF or anti-EGFR therapy. Pumitamig (BNT327/BMS986545) is an investigational bispecific antibody engineered to simultaneously target both PD-L1 and VEGF-A within the tumor and tumor microenvironment, a dual mechanism intended to enhance antitumor immunity and inhibit angiogenesis. Pumitamig plus chemotherapy has shown encouraging efficacy and manageable safety in patients (pts) with solid tumors (Cheng Y, et al. J Thorac Oncol 2025;20[suppl 1]. Abstract 301P; Schmid P, et al. SABCS 2025. Abstract PS1-13-25). This phase 2/3 trial aims to investigate the safety and efficacy of pumitamig and establish if it improves clinical outcomes when added to chemotherapy versus current standard of care in pts with previously untreated mCRC. **Methods:** ROSETTA CRC-203 is a global, randomized, blinded phase 2/3 study. Pts aged $\geq$ 18 years, with ECOG PS 0-1, with previously untreated, unresectable, or mCRC, no microsatellite instability-high/mismatch repair-deficient biomarkers, no BRAF V600E mutation and measurable disease per RECIST v1.1 are eligible. Key exclusion criteria include untreated central nervous system metastases, significant cardiovascular disease, recent or active malignancy, and prior systemic therapy with checkpoint inhibitors or chemotherapy. Pts in the Phase 2 dose-optimization part of the study will be randomized 1:1:1 to receive pumitamig low or pumitamig high dose + FOLFOX (Q2W)/FOLFIRI (Q2W) or bevacizumab + FOLFOX (Q2W)/FOLFIRI (Q2W). The primary endpoint is objective response rate (ORR) by RECIST v1.1 per investigator assessment, with progression-free survival (PFS), and duration of response (DOR) as secondary endpoints. In phase 3, eligible pts will be randomized 1:1 to receive pumitamig at the recommended phase 3 dose + FOLFOX (Q2W)/FOLFIRI (Q2W)/CAPOX (Q3W) or bevacizumab + FOLFOX (Q2W)/FOLFIRI (Q2W)/CAPOX (Q3W), until disease progression or unacceptable toxicity. The primary endpoint is PFS by RECIST v1.1 per blinded independent central review. Overall survival, ORR, and DOR are secondary endpoints. Safety will be monitored throughout the study according to CTCAE v5.0. Recruitment is ongoing. ClinicalTrials.gov ID: NCT07221357. Clinical trial information: NCT07221357. Research Sponsor: Bristol Myers Squibb.

TPS3673 **Poster Session**

Phase II trial of pembrolizumab in combination with odetiglucan for patients with metastatic colorectal adenocarcinoma with liver-predominant disease. First Author: William J. Chapin, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

Background: Liver metastases are associated with resistance to immune checkpoint inhibitors in patients with mismatch repair proficient (MMRp) metastatic colorectal cancer (mCRC). (Beiter JCO 2025) Odetiglucan is a pathogen associated molecular pattern (PAMP) that modulates the tumor microenvironment and may enhance the activity of immune checkpoint inhibition. In syngeneic colon cancer mouse models, the combination of odetiglucan and PD-1/PD-L1 inhibition was associated with a larger proportion of tumor-free mice than either treatment alone. (Jonas Cancer Res. 2017; Fraser Cancer Res. 2016; Chan Frontiers Oncol. 2020) In a mouse model of pancreatic cancer liver metastases, odetiglucan reprogrammed liver-resident macrophages to stimulate tumor-specific T-cell responses, which was associated with reduced cancer cell proliferation and increased sensitivity to anti-PD-1 therapy. (Thomas Nat Commun. 2023) In a clinical trial of anti-PD-1 therapy plus odetiglucan in patients with triple negative breast cancer, tumor regression was observed in 56% of liver lesions classified as target lesions, with one patient experiencing complete regression of both target liver lesions, which remained undetectable after more than 70 weeks of treatment. (Stopeck J Immun. 2025). **Methods:** We are performing a single-center, investigator-initiated, single-arm phase II clinical trial with a Simon two-stage mini-max design of the combination of pembrolizumab with odetiglucan in patients with liver-predominant, MMRp mCRC who have experienced disease progression on standard therapies (3L+ setting). Treatment consists of intravenous infusion of odetiglucan (4mg/kg) and pembrolizumab on day 1 of a 21-day cycle. Patients with prior exposure to immunotherapy or odetiglucan, peritoneal metastases, symptomatic lung or bony metastases, autoimmune conditions requiring systemic immunosuppression, or a history of pneumonitis are excluded. The primary endpoint of the study is objective response by RECIST 1.1. The null hypothesis that the true response rate is 6% will be tested against a one-sided alternative. In the first stage of the study, 13 patients will be accrued and if there are no partial or complete responses, then the study will be stopped for futility. Otherwise, 14 additional patients will be accrued to a total of 27 patients. If four or more responses are observed in 27 patients, then the null hypothesis will be rejected. As of 1/2026, four patients have been enrolled and started study treatment. The study includes pre-treatment and on-treatment research biopsies and longitudinal research blood collection for immune pharmacodynamic profiling to investigate mechanisms of treatment response and resistance. Clinical trial information: NCT07082439. Research Sponsor: Merck.

TPS3674 **Poster Session**

A phase Ib/III randomized double-blinded placebo-controlled study of suvemcitug combined with trifluridine/tipiracil for refractory metastatic colorectal cancer. First Author: Ying Yuan, The Second Affiliated Hospital, Zhejiang University School of Medicine, Department of Medical Oncology, Key Laboratory of Cancer Prevention and Intervention, Ministry of Education, Hangzhou, Zhejiang, China

Background: Colorectal cancer (CRC) is a leading cause of cancer-related death worldwide. For patients with metastatic CRC (mCRC) that has progressed on standard chemotherapies, available treatments offer limited benefit. Notably, the phase III SUNLIGHT trial demonstrated the efficacy and safety of trifluridine/tipiracil (FTD/TPI) in combination with bevacizumab in refractory mCRC. Suvemcitug is a new-generation recombinant humanized anti-VEGF rabbit monoclonal antibody. In the previous clinical trials, suvemcitug demonstrated its favorable safety profile and efficacy signals as a single agent or in combination with chemotherapy for the treatment of mCRC. This study aims to assess the efficacy and safety of the combination of suvemcitug and FTD/TPI in patients with refractory mCRC. **Methods:** This phase Ib/III, randomized, double-blinded, placebo-controlled, multi-cohort study (NCT07361003) consists of two parts, Part 1 (phase Ib) and Part 2 (phase III). Estimated total enrollment is approximately 464 participants: 30 for Part 1 and 434 for Part 2. Patients with mCRC are eligible for participation if they have received chemotherapy based on fluoropyrimidine, oxaliplatin and irinotecan, and have either previously received or are unsuitable for anti-VEGF therapy and anti-EGFR therapy (if RAS wild-type). Part 1: Phase Ib: Participants will be enrolled to receive suvemcitug combined with FTD/TPI. The dose of suvemcitug is 1.5 mg/kg administrated intravenously every two weeks. The primary endpoint is safety and tolerability of suvemcitug. The secondary endpoints include pharmacokinetic (PK) profile of suvemcitug; the incidence, duration, and titer of anti-drug antibodies (ADA); as well as objective response rate (ORR), duration of response (DoR), disease control rate (DCR), progression-free survival (PFS), and overall survival (OS). Part 2: Phase III: Part 2 is designed as a Phase III to further evaluate the antitumor activity of suvemcitug in combination with FTD/TPI in refractory mCRC. Eligible participants will be randomized (1:1 ratio) to receive FTD/TPI in combination with suvemcitug or matching placebo at the dose identified in Part 1. Stratification criteria include primary tumor location, prior bevacizumab exposure, and time from initial metastasis to enrollment. The primary endpoint is OS. The secondary endpoints include PFS, ORR, DoR, DCR, safety, quality of life, PK and immunogenicity (ADA incidence, titer, duration). The exploratory endpoints are correlations among PK, pharmacodynamics, safety and clinical efficacy. Study treatment will continue until progressive disease, unacceptable toxicity, withdrawal of consent, or the investigator's decision to discontinue. Clinical trial information: NCT07361003. Research Sponsor: None.

TPS3675 **Poster Session**

Symbiotic-GI-03: A randomized, double-blind, phase 3 study of first-line PF-08634404, a PD-1/VEGF bispecific antibody, in combination with mFOLFOX6 in patients with metastatic colorectal cancer (mCRC). First Author: Cathy Eng, Vanderbilt Ingram Cancer Center, Nashville, TN

Background: Multi-agent chemotherapy regimens (eg, mFOLFOX6) ± anti-vascular endothelial growth factor (VEGF) or anti-epidermal growth factor regimens are currently the standard of care for patients (pts) with mCRC without targetable mutations. However, the 5-year survival rate remains low at approximately 16% (SEER, 2025). The addition of biological therapies (eg, bevacizumab [bev], an anti-VEGF monoclonal antibody) to immune checkpoint inhibitors (ICIs) has demonstrated a synergistic antitumor effect in solid tumors. However, ICI monotherapy has limited activity in mismatch repair proficient (pMMR)/microsatellite stable (MSS) mCRC. Simultaneous bispecific targeting of programmed death 1 (PD-1) and VEGF in conjunction with cytotoxic chemotherapy has the potential to enhance antitumor activity. PF-08634404 is a fully human immunoglobulin G4 (IgG4) bispecific antibody targeting PD-1 and VEGF. A phase 2 study of PF-08634404 with XELOX or mFOLFOX6 demonstrated promising antitumor activity with a manageable safety profile in first-line (1L) mCRC (Xu X, ESMO 2025; Abstract 796P). **Methods:** Symbiotic-GI-03 (NCT07222800) is an ongoing, double-blind, randomized, phase 3 study evaluating the efficacy and safety of 1L PF-08634404 + mFOLFOX6 vs bev + mFOLFOX6. Inclusion criteria are age ≥18 y; mCRC with measurable disease per RECIST 1.1; no prior systemic therapy for metastatic disease; ECOG PS 0 or 1; and adequate hematologic, hepatic, and renal function. Pts with BRAF V600E-mutant or mismatch repair deficient (dMMR)/microsatellite instability-high (MSI-H) CRC, active central nervous system metastases, or clinically significant risk of hemorrhage/fistula will be excluded. Approximately 800 pts will be randomized 1:1 to receive PF-08634404 + mFOLFOX6 or bev + mFOLFOX6 until disease progression, unacceptable toxicity, withdrawal of consent, or death. Randomization will be stratified by region (North America, Europe, or rest of world), RAS status (mutant or wildtype), and presence of liver metastasis (yes or no). The dual primary endpoints are progression-free survival (PFS) by blinded independent central review and overall survival; for each, a stratified log-rank test will be used to compare arms. Hazard ratios with corresponding 2-sided 95% CIs will be estimated using a stratified Cox proportional hazards model, and medians will be estimated using the Kaplan-Meier method with corresponding 2-sided 95% CIs calculated using the log(-log) method. Secondary endpoints include PFS by investigator, objective response rate, duration of response, PFS after next-line therapy, safety/tolerability, pharmacokinetics, immunogenicity, and patient-reported outcomes. Enrollment began in December 2025. Clinical trial information: NCT07222800. Research Sponsor: This study was sponsored by Pfizer. Medical writing support was provided Eleanor Porteous, MSc, and Akshaya Srinivasan, PhD, of Nucleus Global, an Inizio Company, and was funded by Pfizer.

TPS3676 **Poster Session**

The CO.33/BATTMAN trial: A phase 3 randomized study of botensilimab + balstilimab versus best supportive care in chemorefractory unresectable colorectal adenocarcinoma that is not dMMR/MSI-H. First Author: Jonathan M. Loree, BCCA - Vancouver Cancer Centre, University of British Columbia, Vancouver, BC, Canada

Background: Despite significant progress and newly approved agents, metastatic colorectal cancer (mCRC) has limited prognosis after progressing on standard cytotoxic chemotherapies. Many patients remain well enough for treatment at the time when their cancer is refractory to all available therapy, creating a significant unmet need. Once refractory, patient management with best supportive care (BSC) results in a median overall survival (OS) of 4–6 months. To date, immune checkpoint inhibitors (ICIs) have shown limited activity in mCRC that is not mismatch repair deficient (dMMR) or microsatellite instability-high (MSI-H). Prior data from the CCTG CO.26 randomized phase 2 trial demonstrated doublet ICI with durvalumab + tremelimumab improved OS in refractory mCRC; however, a phase 3 trial was not undertaken. Botensilimab (BOT) is an Fc-enhanced multifunctional anti–CTLA-4 antibody designed to increase efficacy in poorly immunogenic cancers. The combination of BOT with the anti–PD-1 antibody balstilimab (BAL) has shown impressive objective response rates (ORRs), durations of response (DOR), and survival in heavily treated non–MSI-H/dMMR mCRC across phase 1 and 2 studies. The CO.33/BATTMAN trial will evaluate BOT + BAL + BSC versus BSC alone in patients with refractory mCRC that is not MSI-H/dMMR. **Methods:** BATTMAN (NCT07152821) is an international multi-centre, open-label randomized phase 3 trial that will be conducted in Canada (CCTG), Australia/New Zealand (AGITG) and France (Unicancer). Eligible patients will be ≥18 years old, have received and progressed on or been intolerant of all available therapies, have an Eastern Cooperative Oncology Group performance status (ECOG PS) of 0/1, have RECIST 1.1 measurable/evaluable disease, have a life expectancy of ≥12 weeks, and have adequate end organ function without concurrent illness contraindicating ICI. Exclusion criteria include: prior organ transplant or primary immunodeficiency, ongoing use of non-physiologic corticosteroid dosing, autoimmune disorders requiring ongoing management, and prior ICI exposure. The trial's statistical plan will ascertain efficacy of BOT and BAL in all comers, as well as key subgroups based on the presence or absence of liver metastases. A planned 834 patients will be randomized 1:1 to BOT (75 mg IV every 6 weeks up to 4 doses) + BAL (450 mg IV every 3 weeks until progression) + BSC or BSC alone, with stratification for region of recruitment, ECOG PS, and presence of liver metastases. The primary endpoint is OS, with secondary endpoints including progression-free survival, ORR, clinical benefit rate, quality of life, safety, and toxicity, with correlative studies and economic evaluations planned. Support for this study is provided by: The Canadian Cancer Society and Agenus Inc. Clinical trial information: NCT07152821. Research Sponsor: Canadian Cancer Society; Agenus.

TPS3677 **Poster Session**

A phase II exploratory study of iparomlimab and tuvonralimab (QL1706) combined with bevacizumab in patients with locally advanced or metastatic MSI-H/dMMR colorectal cancer. First Author: Jun Wang, Department of Oncology, The First Affiliated Hospital of Shandong First Medical University, Jinan, China

Background: Microsatellite instability-high/mismatch repair-deficient (MSI-H/dMMR) colorectal cancer (CRC) is highly responsive to immune checkpoint inhibitors (ICIs). PD-1 monotherapy or PD-1/CTLA-4 dual blockade are standard options for locally advanced or metastatic disease, but a significant proportion of patients still show no response to these regimens. Evidence suggests that vascular endothelial growth factor (VEGF) signaling mediates an immunosuppressive tumor microenvironment (TME). Combining anti-VEGF agents with ICIs may potentially normalize the inhibitory TME, and thereby could enhance anti-tumor immunity and improve response rates in this population. QL1706 is a novel bifunctional antibody combination targeting PD-1 (iparomlimab) and CTLA-4 (tuvonralimab). This Phase II exploratory study aims to investigate the efficacy and safety of QL1706 in combination with anti-VEGF agent bevacizumab in locally advanced or metastatic CRC patients with MSI-H/dMMR. **Methods:** This single-arm, open-label, multicenter, Phase II exploratory study is designed to evaluate the efficacy and safety of QL1706 plus bevacizumab in patients with MSI-H/dMMR advanced CRC. Eligible patients are adults aged 18 to 80 years with histologically confirmed locally advanced or metastatic CRC and who have an MSI-H/dMMR status via immunohistochemistry or polymerase chain reaction. Key inclusion criteria include at least one measurable target lesion per RECIST v1.1, an ECOG Performance Status of 0-1, and no prior immunotherapy for advanced disease. The systemic regimen consists of QL1706 (5 mg/kg) and bevacizumab (7.5 mg/kg) administered intravenously every 3 weeks (Q3W). Treatment continues until disease progression, unacceptable toxicity, or a maximum of 2 years. The primary endpoint is the objective response rate (ORR) assessed by investigators per RECIST v1.1. Secondary endpoints include disease control rate, duration of response, progression-free survival, overall survival, and landmark survival rates at 6, 12, and 24 months. Safety is monitored via NCI CTCAE v5.0. Efficacy assessments, including chest CT and enhanced abdominal/pelvic CT/MRI, are performed every 12 weeks. Statistical power is based on an estimated ORR of 80%; with a 95% confidence interval width of 35%, a total of 22 subjects are required (supplemented by a Simon's two-stage design for the broader cohort if applicable). The study has received ethics committee approval, and patient enrollment is currently ongoing. Clinical trial information: NCT07009145. Research Sponsor: None.

TPS3678 **Poster Session**

A phase 1, first-in-human (FIH), dose-escalation and dose-optimization study to evaluate the safety, tolerability, pharmacokinetics, and anti-tumor activity of CBI-1214 T-cell engager in participants with advanced or metastatic microsatellite-stable (MSS)/microsatellite instability–low (MSI-L) colorectal cancer (CRC). First Author: Alexander I. Spira, NEXT Oncology – Virginia, Fairfax, VA

Background: Advanced and metastatic colorectal cancer (CRC) remains an area of significant unmet clinical need, particularly for patients with MSS/MSI-L tumors. In recent years, there have been several advancements in the treatment of solid tumors with T cell engagers. Our ATLAS scRNA-seq based discovery platform identified LY6G6D as a highly-specific tumor-associated antigen in advanced and metastatic CRC. CBI-1214, a CD3 bispecific T cell engager targeting LY6G6D with potent in vitro and in vivo activity even at low LY6G6D expression levels of ~300 copies/cell (*Yigit B et al, AACR 2025*), is being developed for the treatment of patients with advanced or metastatic MSS/MSI-L CRC. **Methods:** This ongoing, open-label FIH study (CBI-1214-001) is being conducted to evaluate the safety, tolerability, pharmacokinetics (PK), and anti-tumor activity of CBI-1214 and to determine the maximum tolerated dose (MTD) and/or optimal biological dose (OBD) in participants with advanced or metastatic MSS/MSI-L CRC who have exhausted at least one prior line of systemic treatment and do not qualify for available targeted treatment options for actionable genomic alterations. Additional eligibility criteria include: at least 18 years of age, measurable disease (as defined by RECIST v1.1), available archival tumor tissue sample or a fresh tumor sample, ECOG PS 0 or 1, as well as adequate hematologic and organ functions. Patients whose CRC tumor tissues have been identified as dMMR or MSI-H are excluded. The study is conducted in two parts: Part 1 dose escalation, which starts with Part 1a as accelerated dose escalation, followed by Part 1b escalation, which is based on a modified toxicity probability interval (mTPI-2) design, and Part 2, which is designed as a randomized dose optimization study to select the final recommended phase 2 dose (RP2D). For both parts of the study, the study intervention is administered as monotherapy, given as an intravenous (IV) infusion, in 21-day treatment cycles, with a step-up option. After an up-to-28-day screening period, eligible patients receive study medication and are followed for their entire treatment period plus a follow-up period of approximately 90 days. The study is open for recruitment in the United States (NCT07321106). Clinical trial information: NCT07321106. Research Sponsor: None.

TPS3679 **Poster Session**

A study evaluating microbiome modulation therapy in patients undergoing first-line therapy for metastatic colorectal cancer. First Author: Emily Noelle Kinsey, Virginia Commonwealth University, Richmond, VA

Background: Colorectal cancer (CRC) is the second leading cause of cancer-related mortality worldwide. Despite advances in systemic therapy, the 5-year overall survival for metastatic CRC remains poor. Emerging evidence suggests that the gut microbiome influences CRC development, progression, as well as chemotherapy resistance. There is strong preclinical data showing the association of *Fusobacterium nucleatum* and *Escherichia coli* with poor outcomes and chemotherapy resistance in patients with CRC. Younger patients and Black patients have been found to have a high-level colonization with *F nucleatum*, which could potentially contribute to healthcare disparities. If the amount of cancer-associated bacteria in the microbiome can be reduced, patients may respond better to chemotherapy and have improved outcomes. Preclinical studies indicate that targeting these bacteria with antibiotics may enhance chemotherapy efficacy. Aspirin may also be beneficial as it affects gene expression and inhibits *Fusobacterium nucleatum* with differential effects at varying drug concentrations. Our study evaluates the feasibility, safety, and preliminary efficacy of adding Microbiome Modulation Therapy (MBMT), including ciprofloxacin, metronidazole, +/- aspirin, to standard first-line chemotherapy in patients with metastatic CRC. **Methods:** This is a two-arm, noncomparative phase II trial enrolling adults (≥18 years) with stage IV CRC and measurable disease by RECIST 1.1. Eligible patients must have ECOG performance status 0–2 and planned first-line 5FU-based standard of care chemotherapy. Patients are excluded if they have recent antibiotic use to treat an infection within 30 days of treatment start (prophylactic preoperative antibiotics are allowed), have had a total colectomy, or are taking probiotic treatments. Patients are randomized to standard chemotherapy alone (investigators choice) or chemotherapy plus MBMT (ciprofloxacin, metronidazole, +/- aspirin for 28 days). The primary endpoint is objective response rate (ORR) per RECIST 1.1. Secondary endpoints include overall survival (OS), progression-free survival (PFS), safety, and tolerability of MBMT. Exploratory endpoints include changes in microbiome composition as measured by shotgun sequencing of fecal samples at baseline and after one month of treatment with chemotherapy +/- MBMT. Correlative studies will use shotgun sequencing to assess microbiome signatures, microbiota diversity, and changes with treatment. Correlative analyses will explore microbiome modulation as a novel therapeutic strategy to overcome chemoresistance in metastatic CRC. Enrollment is ongoing at Virginia Commonwealth University Massey Comprehensive Cancer Center in Richmond, Virginia. Clinical trial information: NCT06728072. Research Sponsor: Massey Comprehensive Cancer Center; American Cancer Society, Institutional Research Grant.

TPS3680 **Poster Session**

CONCEPT (combination of cetuximab plus fruquintinib treatment ± immunotherapy): A multicenter, randomized, open-label phase II trial in first-line pMMR *RAS/BRAF* wild-type unresectable metastatic colorectal cancer. First Author: Yue Liu, Colorectal Surgery and Oncology, Key Laboratory of Cancer Prevention and Intervention, Ministry of Education, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, Zhejiang, China

Background: In pMMR unresectable metastatic colorectal cancer (mCRC), first-line standards combine cytotoxic chemotherapy with targeted agents (anti-EGFR or anti-VEGF). A chemotherapy-sparing strategy may be clinically relevant for selected patients, and biologically supported by potential synergy between EGFR inhibition and VEGFR blockade, with immunotherapy potentially enhanced by vascular normalization and microenvironment modulation. CONCEPT evaluates the safety and antitumor activity of cetuximab-β plus fruquintinib, with or without immune checkpoint blockade, as a first-line option in pMMR RAS/BRAF wild-type unresectable mCRC. **Methods:** CONCEPT is an open-label, multicenter, randomized phase II trial. Key eligibility: age 18–85, ECOG 0–1, histologically confirmed colorectal adenocarcinoma, pMMR, KRAS/NRAS/BRAF wild-type, unresectable metastatic disease, and ≥1 measurable lesion per RECIST v1.1. Planned N=70; randomization 1:1:1 to: A) cetuximab-β 500 mg/m² IV q2w + fruquintinib 5 mg PO QD (3 weeks on/1 week off); B) regimen A + PD-1 antibody 200 mg IV q4w; C) regimen A + PD-1/CTLA-4 antibody 5 mg/kg IV q4w. The study uses a seamless two-stage selection design: initial cohort (10 patients/arm) to assess early safety/activity, followed by expansion of one or two selected arm(s) (+20 patients per selected arm). Safety assessments are performed each cycle; radiologic tumor assessment is every 2 cycles. Primary endpoints: progression-free survival (PFS) and safety. Secondary endpoints include objective response rate (ORR), disease control rate (DCR) and overall survival (OS). The study is registered with ClinicalTrials.gov (NCI 07257653). Clinical trial information: NCI 07257653. Research Sponsor: None.

TPS3681 **Poster Session**

Bevacizumab plus encorafenib-cetuximab in BRAF V600E mutated metastatic colorectal cancer (mCRC): A phase II study with a safety lead-in cohort (the BRAVE trial). First Author: Javier Ros Montañá, Vall d'Hebron Institute of Oncology (VHIO), Vall d'Hebron University Hospital, Barcelona, Spain

Background: Encorafenib plus cetuximab is the standard of care for patients with *BRAF* V600E mutant, microsatellite-stable (MSS) mCRC, BRAF inhibitor-naïve, whose disease has progressed after 1-2 prior lines of chemotherapy. However, all patients eventually experience disease progression, and progression-free survival (PFS) remains modest. Therefore, there is an unmet need to enhance the efficacy of encorafenib-based combinations in *BRAF*-mutant mCRC. Preclinical data from rodent models treated with BRAF inhibitors have demonstrated upregulation of hypoxia-related genes (VEGFA, ADM, and CXCR4), and alterations in tumor vessel architecture. Based on these observations, rodent models treated with BRAF inhibitors in combination with anti-VEGF therapy achieved a meaningful improvement in PFS. In this trial, we hypothesize that encorafenib–cetuximab with bevacizumab will result in synergistic activity leading to durable responses in patients with refractory *BRAF*-mutant mCRC. **Methods:** The BRAVE trial (NCT06411600) is a multicenter, single-arm, phase Ib/II study evaluating the safety and efficacy of encorafenib–cetuximab–bevacizumab. Patients must have progressed to 1-2 previous lines and have a *BRAF* V600E-mutant, MSS tumor. Previous treatment with BRAF inhibitors or antiEGFR was not allowed. All patients receive encorafenib 300 mg vo QD, cetuximab 500 mg iv Q2W, and bevacizumab 5 mg/kg iv Q2W, administered in 28-day cycles. The primary endpoints are dose-limiting toxicities (DLTs) and 6-month PFS (6mPFS). The study follows a Simon two-stage design. A sample size of 89 evaluable patients is required to detect an increase in 6mPFS to 49% in the study population, compared with a 36% 6mPFS achieved with encorafenib plus cetuximab in the BEACON trial, using a one-sided type I error of 0.05 and 80% statistical power. As there was no prior evidence on the safety of this combination, a safety lead-in (SLI) phase (n=9) was included to evaluate potential DLTs. An Independent Data Safety Monitoring Board (IDSMB) reviewed the toxicity profile and DLTs granted continuation of the study on April 1, 2025. Following completion of the SLI phase and IDSMB evaluation, the study proceeded to two subsequent stages. Stage I enrolled 41 additional patients (completed on December 12, 2025). A preplanned interim analysis (IA) is being performed before proceeding to Stage II. If fewer than 19 of the first 50 patients achieve 6mPFS, the study will be discontinued due to lack of efficacy. If 19 or more of the first 50 patients achieve 6mPFS, Stage II will enroll an additional 39 patients. Recruitment is currently on hold pending the planned IA. Biomarker analyses include plasma sample collection at screening, on C1D15, and at end of treatment, as well as tumor biopsies (optional) at baseline and at disease progression to study mechanism of sensitivity and resistance. Clinical trial information: NCT06411600. Research Sponsor: Insituto de Salud Carlos III.

TPS3682 **Poster Session**

A randomized, active-controlled phase 3 study of ivonescimab + FOLFOX versus bevacizumab + FOLFOX as first-line treatment of metastatic colorectal cancer (mCRC): HARMONi-GI3. First Author: Aparna Raj Parikh, Department of Medicine, Division of Hematology/Oncology, Mass General Brigham Cancer Center, Harvard Medical School, Boston, MA

Background: Fluorouracil (5-FU)-based chemotherapy plus an anti–vascular endothelial growth factor (VEGF) or anti–epidermal growth factor receptor (EGFR) therapy is recommended as first-line treatment for many patients with mCRC; however, prognosis is still poor, with a 5-year survival rate of $<$30%. The investigational, anti–programmed cell death protein 1 (PD-1)- and VEGF-bispecific antibody ivonescimab is approved in China for non-small cell lung cancer (NSCLC) and is currently being evaluated as monotherapy or in combination with chemotherapy in global phase 3 clinical trials for NSCLC, and in other tumor types including colorectal cancer. **Methods:** HARMONi-GI3 (NCT07228832) is a randomized, active-controlled, double-blind, multiregional, phase 3 trial to compare the efficacy and safety of ivonescimab + 5-FU, oxaliplatin, and leucovorin (mFOLFOX6) versus bevacizumab + mFOLFOX6 in patients with mCRC who are not candidates for surgical resection, have not previously received systemic therapy for metastatic disease, and have an Eastern Cooperative Oncology Group performance status score of 0 or 1. Patients with microsatellite instability-high or mismatch repair deficient disease, and with BRAF V600E mutation or dihydropyrimidine dehydrogenase deficiency, will be excluded. Approximately 600 patients will be randomly assigned (1:1) to receive ivonescimab 20 mg/kg + mFOLFOX6 or bevacizumab + mFOLFOX6 every 2 weeks for up to 4 months, followed by maintenance with ivonescimab + 5-FU and leucovorin or bevacizumab + 5-FU and leucovorin until disease progression, intolerable toxicity, or initiation of new anti-tumor therapy. Randomization will be stratified according to geographic region (East Asia, Europe, North America), liver metastases at study entry (absence or presence), and rat sarcoma virus tumor mutational status (RAS; mutant or wild-type). The hypothesis of this study is that ivonescimab + mFOLFOX6 has superior efficacy to bevacizumab + mFOLFOX6 in patients with mCRC who have not previously received systemic therapy for metastatic disease, as determined by progression-free survival (PFS). The primary endpoint is PFS (assessed by independent radiology review committee per Response Evaluation Criteria in Solid Tumors, v1.1). Secondary endpoints are overall survival, objective response rate, duration of response, safety, pharmacokinetics of ivonescimab + mFOLFOX6, and immunogenicity. All patients will have regular tumor evaluations every 8 weeks until week 48, then every 12 weeks until disease progression, loss to follow-up, death, withdrawal, or study closure. HARMONi-GI3 is currently recruiting participants. Clinical trial information: NCT07228832. Research Sponsor: Summit Therapeutics, Inc.

TPS3683 **Poster Session**

INCA033890-303: A randomized, double-blind, phase 3 study of FOLFOX and bevacizumab with or without INCA33890 in the first-line treatment of metastatic microsatellite-stable colorectal cancer. First Author: Van K. Morris II, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Immune checkpoint inhibitors have demonstrated limited efficacy in the treatment of microsatellite stable colorectal cancer (MSS CRC), especially when the liver is involved. Transforming growth factor β (TGFβ) signaling within the tumor microenvironment suppresses T-cell proliferation and effector function, contributing to an immune-excluded phenotype. Although clinical targeting of the TGFβ pathway has been previously attempted, these approaches have been hampered by limited efficacy and significant toxicity. INCA33890 is a first-in-class bispecific antibody targeting both TGFβ receptor 2 (TGFβR2) and programmed cell death protein 1 (PD-1). This molecule is designed to inhibit TGFβR2 and PD-1 signaling specifically in PD-1–positive cells, sparing PD-1–negative cells from TGFβ inhibition. In the phase 1 INCA 33890-101 study (NCT05836324), INCA33890 demonstrated a manageable safety profile and durable single-agent activity in patients with refractory MSS CRC, including in patients with active liver metastases. The monotherapy objective response rate (ORR) was 15.2% overall (n = 105), including 12.0% in patients with liver metastases (n = 75) and 23.3% (n = 30) in patients without liver metastases. **Methods:** The multicenter, global, phase 3 INCA033890-303 study (NCT07284849) activated in December 2025 and is planned to open at 225 sites across 23 countries. The primary objective of this study is to evaluate the efficacy of INCA33890 versus intravenous placebo, each in combination with FOLFOX and bevacizumab, as first-line treatment for patients with previously untreated, histologically confirmed, unresectable metastatic MSS CRC. Prior neoadjuvant or adjuvant therapy is allowed provided there was no recurrence within 12 months of treatment completion. Key exclusion criteria include microsatellite instability-high (MSI-H) or mismatch repair-deficient (dMMR) status, *BRAF V600E* mutation, untreated or progressing brain metastases, and active autoimmune disease requiring systemic immunosuppression. Approximately 700 patients will be randomized 1:1 to receive intravenous INCA33890 or placebo, each in combination with FOLFOX and bevacizumab. Randomization will be stratified by tumor sidedness, the presence of liver metastases, and programmed death-ligand 1 (PD-L1) score. The primary endpoint is progression-free survival as assessed by investigators. The key secondary endpoint is overall survival. Additional secondary endpoints are ORR, safety and tolerability, duration of response, and patient-reported outcomes. Trial enrollment is ongoing. Clinical trial information: NCT07284849. Research Sponsor: Incyte Corporation.

TPS3684 **Poster Session**

Fruquintinib in combination with tislelizumab vs trifluridine/tipiracil and bevacizumab in MSS mCRC without active liver metastases: The IKF-080/QUINTIS trial. First Author: Joseph Tintelnot, University Cancer Center Hamburg (UCCH), University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Patients with metastatic colorectal cancer (mCRC) who progress after treatment with fluoropyrimidines, oxaliplatin, irinotecan, anti-angiogenic agents, and anti-EGFR therapies have limited therapeutic options and a poor prognosis. Median overall survival (mOS) is approximately 6 months with single-agent regorafenib or trifluridine/tipiracil. The addition of bevacizumab to trifluridine/tipiracil has improved mOS to 10.8 months, while fruquintinib, a selective VEGFR-1–3 inhibitor, demonstrated a mOS of 7.4 months compared with 4.8 months for placebo in refractory mCRC. However, combinations of tyrosine kinase inhibitors and immune checkpoint inhibitors have shown clinical benefit, primarily in patients with microsatellite-stable mCRC without liver metastases, likely due to liver-associated immunosuppression. The QUINTIS trial evaluates whether fruquintinib plus the PD-1 antibody tislelizumab can improve outcomes in this clinically defined subgroup compared with the current standard of care of trifluridine/tipiracil plus bevacizumab. **Methods:** QUINTIS is a prospective, randomized, open-label, multicenter phase II trial enrolling 140 patients with metastatic colorectal adenocarcinoma without active liver metastases who have previously received fluoropyrimidines, oxaliplatin, irinotecan, bevacizumab, and, when indicated, an EGFR inhibitor. Participants are randomized 1:1 to Arm A (experimental): fruquintinib 5 mg orally once daily (days 1–21 of a 28-day cycle) plus tislelizumab 400 mg intravenously on day 1 every 6 weeks; or Arm B (control): trifluridine/tipiracil 35 mg/m² orally twice daily (days 1–5 and 8–12 of a 28-day cycle) plus bevacizumab 5 mg/kg intravenously every 2 weeks. No prior treatment with the study drugs is permitted. Randomization is stratified by time since prior anti-angiogenic therapy ($<$ 12 vs. $\geq$12 months), BRAF/RAS mutation status, and history of liver metastases (never vs. treated). The primary endpoint is progression-free survival; secondary endpoints include overall response, overall survival, and quality of life. Translational research includes tumor, blood, and stool sampling to explore biomarkers of response and resistance, including systemic inflammation and the diet–microbiota–immune axis. Patient enrolment started in October 2025, and enrolment will take place at 30 sites. Clinical trial information: EU CTIS No. 2024-519111-34-00. Research Sponsor: None.

TPS3685 **Poster Session**

NSABP FC-13 (EMPIRE): A phase II platform study of cemiplimab monotherapy or cemiplimab-based combinations in patients with colorectal cancer and minimal residual disease (MRD) after definitive therapy. First Author: Anwaar Saeed, NSABP Foundation and UPMC Hillman Cancer Center, University of Pittsburgh School of Medicine, Pittsburgh, PA

Background: Patients with microsatellite-stable (MSS) colorectal cancer (CRC) who are ctDNA-positive following surgery and chemotherapy have a high risk of recurrence and limited treatment options. Immune checkpoint blockade with PD-1/PD-L1 inhibitors, alone or with other immune modulators, may be most effective in early-stage disease or in patients without liver metastases. However, no approved therapies currently exist for patients with MSS CRC and ctDNA-positivity after curative-intent therapy, making this high-risk population an area of critical unmet need and opportunity for new drug development. NSABP FC-13 (EMPIRE) is a Phase II platform trial evaluating cemiplimab alone or in combination with novel agents in this high-risk MRD setting, wherein ctDNA clearance serves as an early surrogate marker of therapeutic activity. **Methods:** This multicenter Phase II platform study randomizes patients with MSS stage II–III or oligometastatic stage IV CRC who are ctDNA-positive within 12 weeks of completing definitive therapy (surgery ± chemotherapy/chemoradiotherapy) to one of three arms: (1) Cemiplimab 350 mg IV q3w × 1 year; (2) Cemiplimab 350 mg + fianlimab 1600 mg IV q3w × 1 year; (3) Cemiplimab 350 mg + REGN7075 2700 mg IV q3w × 1 year. Eligibility includes ECOG 0–1, adequate organ function, and absence of radiographic recurrence at enrollment. Assessments include serial tumor-informed ctDNA testing (Signatera, Natera, Inc.), imaging, labs, and safety monitoring. The primary endpoint is ctDNA clearance at 12 weeks without radiographic recurrence. Secondary endpoints include recurrence-free survival (RFS), safety, ctDNA kinetics, and patterns of recurrence. Statistical design: Arm 1 follows a Simon two-stage design with up to 33 patients (α=0.047, power=0.80), and Arms 2 & 3 enroll up to 23 patients each (single-stage; α=0.05, power=0.78). Status: Enrollment began in September 2025 across NSABP Foundation sites and is ongoing. Clinical trial information: NCT07058012. Research Sponsor: Regeneron; Natera, Inc.; NSABP Foundation, Inc.

TPS3686 **Poster Session**

NRG-GI008: Colon adjuvant chemotherapy based on evaluation of residual disease (CIRCULATE-NORTH AMERICA). First Author: Arvind Dasari, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Currently, there are no biomarkers validated prospectively in randomized studies for resected colon cancer (CC) to determine need for adjuvant chemotherapy (AC). However, circulating tumor DNA (ctDNA) represents a highly specific and sensitive approach (especially with serial monitoring) for identifying minimal/molecular residual disease (MRD) post-surgery in CC patients (pts), and may outperform traditional clinical and pathological features in prognosticating risk for recurrence. CC pts who do not have detectable ctDNA (ctDNA–) are at a much lower risk of recurrence and may be spared the toxicities associated with AC. Furthermore, for CC pts with detectable ctDNA (ctDNA+) who are at a very high risk of recurrence, the optimal AC regimen has not been established. We hypothesize that for pts whose CC has been resected, ctDNA status may be used to risk-stratify for making decisions about AC. **Methods:** In this prospective phase II/III trial, up to 1,912 pts with resected stage IIB, IIC, and III CC will be enrolled. Based on the post-operative ctDNA status using personalized and tumor-informed assay (Signatera, bespoke assay), those who are ctDNA– (Cohort A) will be randomized to immediate AC with fluoropyrimidine (FP)+oxaliplatin (Ox) for 3-6 mos per established guidelines *v* serial ctDNA monitoring. Patients who are ctDNA+ post-operatively, or with serial monitoring (Cohort B), will be randomized to FP+Ox *v* more intensive AC with addition of irinotecan (I) for 6 mos. One cycle of chemotherapy is allowed while awaiting ctDNA testing results for cohort assignment. The primary endpoints for Cohort A are time to ctDNA+ status (phase II) and disease-free survival (DFS) (phase III) in the immediate *v* delayed AC arms. The primary endpoint for Cohort B is DFS in the FP+Ox *v* FP+Ox+I arms for both phase II and phase III portions of the trial. Secondary endpoints include prevalence of detectable ctDNA post-operatively, time-to-event outcomes (overall survival and time to recurrence) by ctDNA status, and the assessment of compliance to adjuvant therapy. Biospecimens including archival tumor tissue, as well as post-operative plus serial matched/normal blood samples, will be collected for exploratory correlative research. Active enrollment across the NCTN started in June 2022 with CCTG sites joining in August 2023. Accrual is 1,123/1,912 (as of 1/20/2026). *Drs. Dasari and Lieu contributed equally to the development of this trial. Clinical trial information: NCT05174169. TPS3687 **Poster Session**

Node-sparing modified short-course radiotherapy combined with capecitabine and PD-1/CTLA-4 for MSS early, middle, and low rectal cancer (mRCAT-E): An open-label, single-arm, prospective multicenter clinical trial. First Author: Zhangfa Song, Department of Colorectal Surgery, Sir Run Run Shaw Hospital, School of Medicine, Zhejiang University, Hangzhou, China

Background: The standard treatment for early-stage rectal cancer is radical resection. For patients' organ preservation and quality of life improvement, preoperative radiotherapy plus chemotherapy then "watch-and-wait" are also recommended. But the clinical complete response (cCR) rate after chemoradiotherapy is only about 30~40%. Recent studies have shown that combining radiotherapy with PD-1 blockage can improve pathological complete response (pCR) rates to 40~50% for proficient mismatch repair (pMMR) or microsatellite stable (MSS) locally advanced rectal cancer (LARC) patients. However, the irradiation to tumor-draining lymph nodes (TDLNs) may impair T-cell immunity and reduce response to immunotherapy. Our previous phase II trial demonstrated that node-sparing modified short-course radiotherapy combined with chemotherapy and PD-1 blockade could achieve a high pCR rate of 78.8% and reduce radiation-related toxicity in pMMR/MSS LARC.[1] Iparomlimab/tuvonralimab is a novel bifunctional antibody, containing a mixture of anti-PD-1 IgG4 antibody iparomlimab and anti-CTLA-4 IgG1 antibody tuvonralimab, produced in a fixed ratio (2:1) from the same single cell and manufactured together as one product.[2] In this trial, we hypothesize that node-sparing modified short-course radiotherapy combined with capecitabine and PD-1/CTLA-4 may induce synergistic activity and substantially improve CR rates while reducing radiation-related toxicity. **Methods:** This is a single-arm, prospective, multicenter, phase II study across 3 hospitals in China. The main inclusion criteria includes rectal cancer within 7 cm from the lower edge of the tumor to the anal verge and the clinical stage is cT2-3N0M0, MSI-L/MSS or pMMR. A total of 52 patients will receive node-sparing modified short-course radiotherapy of 25 Gy delivered in 5 daily fractions to the primary tumor bed (excluding TDLNs). Beginning on treatment Day 8, patients will receive 4 cycles of capecitabine (1,000 mg/m², D1-14, q3w) and iparomlimab/tuvonralimab (5 mg/kg, D1, q3w). Tumor response will be assessed 1-2 weeks after the last chemo-immunotherapy. Patients with cCR enter a watch-and-wait program, while non-cCR proceed to local excision or total mesorectal excision. The primary endpoint is the CR rate (cCR and pCR). Secondary endpoints include organ preservation rate, 3-year local recurrence rate, overall survival, toxicity, and quality-of-life measures. As of January 2025, 5 of the planned 52 patients have been enrolled. The Data Monitoring Committee (DMC) reviewed the trial in December 2024 and recommended continuing as planned. Clinical trial information: NCT07068763. References: (1) Annals of Oncology (2024) 24 (suppl_1): 1-20. 10.1016/iotech/iotech100744; (2) Zhao et al. Journal of Hematology & Oncology (2023) 16:50. TPS3688 **Poster Session**

A phase 2 randomized study comparing telisotuzumab adizutecan monotherapy with standard of care in patients with post-adjuvant circulating tumor DNA–positive colorectal cancer. First Author: Kanwal Pratap Singh Raghav, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Curative intent standard of care (SOC) management of colorectal cancer (CRC) involves surgical tumor removal, followed by adjuvant therapy and active surveillance (AS). Presence of circulating tumor DNA (ctDNA) in the absence of radiographic evidence of disease is emerging as a reliable biomarker for determining molecular residual disease in CRC and in predicting recurrence after definitive therapy. Telisotuzumab adizutecan (Temab-A) is an antibody-drug conjugate that targets c-Met protein and is conjugated to a topoisomerase 1 (Top1) inhibitor payload. c-Met protein is ubiquitously expressed on CRC tumor cells. Temab-A has shown a manageable safety profile and promising antitumor activity in patients (pts) with advanced solid tumors, including CRC (NCT05029882). Herein, we describe a Phase 2 study of Temab-A monotherapy in pts with ctDNA-positive CRC after adjuvant therapy compared with AS. **Methods:** This open-label, randomized, global, multicenter, Phase 2 study (NCT07023289) includes adults (≥18 yrs) with histologically confirmed adenocarcinoma of the colon or rectum. Surgical tumor material must be available and submitted for Signatera personalized panel and assessment of c-Met protein levels. Pts must have received a total of ≥3 mos of perioperative and/or platinum-based doublet adjuvant therapy, have no radiographic evidence of disease as determined by CT scans and liver MRI, and be ctDNA-positive within the first year after the end of adjuvant therapy. Approximately 140 pts will be randomized (1:1) to receive either Temab-A (2.4 mg/kg, IV, Q3W, N=70) or AS only (N=70). Randomization will be stratified by oligometastatic versus nonmetastatic and by the timing of enrollment. Japan will have a separate randomization schedule stratified by the same factors. During 9 mos of treatment (12 cycles [C], 21 days [D] per C) or AS, pts will undergo monitoring for disease recurrence through CT scans (Q6W) and ctDNA testing (on C2D1, C3D1, C4D1, at 6 and 9 mos). Study follow-up will occur every 3 mos for the first 2 yrs and every 6 mos for the 3 yrs thereafter. The Table shows study objectives and endpoints. Clinical trial information: NCT07023289. Research Sponsor: None.

Objectives	Endpoints
Primary	
Evaluate efficacy of Temab-A	Disease-free survival by investigator
Secondary	
Evaluate clinical outcomes of Temab-A	ctDNA clearance at 6 mos after randomization Overall survival
Safety	
Evaluate safety/tolerability of Temab-A	Adverse event type, frequency, seriousness, and severity Treatment-emergent adverse events leading to treatment discontinuation and dose interruption
Pharmacokinetics (PK)	
Evaluate PK and immunogenicity of Temab-A	Serum concentration of: Temab-A conjugate Total antibody Plasma concentration of Top1 inhibitor

TPS3689 **Poster Session**

Phase 2 study of adjuvant botensilimab in combination with balstilimab in patients with microsatellite-stable colorectal cancer and persistent circulating tumor DNA following surgery and chemotherapy. First Author: Neil Howard Segal, Memorial Sloan Kettering Cancer Center, New York City, NY

Background: In patients with localized microsatellite stable (MSS) colorectal cancer (CRC), detection of circulating tumor DNA (ctDNA) after completion of definitive therapy indicates the presence of minimal residual disease (MRD) and predicts metastatic recurrence within months. Novel adjuvant therapies to prevent recurrence are very much needed. Botensilimab (BOT) is an Fc-enhanced multifunctional anti-cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) antibody designed to expand therapy to cold/poorly immunogenic solid tumors, such as MSS CRC. BOT plus balstilimab (BAL; PD-1 inhibitor) has previously demonstrated deep, durable responses in treatment-refractory metastatic MSS CRC and no active liver metastases. We hypothesize that treatment of MRD with effective immunotherapy in patents with MSS CRC after definitive therapy will prevent tumor recurrence. **Methods:** This investigator-initiated, open label, Phase 2 study evaluates the efficacy of BOT/BAL in patients with stage III MSS CRC (cohort 1) or colorectal liver metastases (CRLM) (cohort 2) and MRD following definitive treatment, including surgery and pre-operative chemotherapy. The study is being conducted in 2 parts. Part 1 aims to determine ctDNA clearance, as a surrogate for improved survival. Patients receive BOT/BAL for 6 months followed by BAL alone for 6 months. With a total of 27 patients per cohort, and using an exact single-stage binomial design, we will have 80% power to detect an improvement in ctDNA clearance from 5% to 20% with a type I error rate of 5%. If part 1 is successful, then part 2 of the study may proceed as a randomized, placebo-controlled, double-blind, multicenter study to assess improvement in recurrence-free survival. Translation studies are planned to correlate tumor and immune characteristics with ctDNA clearance and clinical endpoints to further our understanding of immune responsiveness in the setting of MRD in MSS CRC. Enrollment to the study is currently ongoing. Clinical trial information: NCT07227636. Research Sponsor: None.

LBA4000 **Oral Abstract Session**

Efficacy and safety results from EMERALD-3: A phase 3, randomized study of tremelimumab plus durvalumab with or without lenvatinib combined with transarterial chemoembolization (TACE) in participants (pts) with unresectable embolization-eligible hepatocellular carcinoma (eeHCC). First Author: Ghassan K. Abou-Alfa, Memorial Sloan Kettering Cancer Center; Weill Medical College at Cornell University, New York, NY

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

Camrelizumab (C) plus rivoceranib (R) with transarterial chemoembolization (TACE) vs TACE alone in unresectable hepatocellular carcinoma (uHCC): A randomized, phase 3 trial. First Author: Wei-Dong Jia, Department of General Surgery, The First Affiliated Hospital of University of Science and Technology of China, Hefei, China

Background: The combination of C (anti–PD-1 antibody) + R (VEGFR2 tyrosine kinase inhibitor) significantly improved progression-free survival (PFS) and overall survival (OS) vs sorafenib as first-line treatment for advanced HCC, and improved event-free survival vs surgery alone as perioperative treatment for resectable HCC. We conducted a phase 3 trial evaluating C+R with TACE in intermediate-stage HCC and here present data from the protocol-specified PFS interim analysis (IA). **Methods:** In this multicenter, open-label, phase 3 trial, patients (pts) with TACE-eligible uHCC, Child-Pugh A, ECOG performance status (PS) 0–1 and no extrahepatic spread were randomized 1:1 to receive C (200 mg, iv, Q3W) + R (250 mg, po, QD) + TACE or TACE alone. TACE (cTACE or DEB-TACE) was administered at the investigator (INV)'s discretion; C+R continued until loss of clinical benefits, unacceptable toxicities, or other protocol-specified criteria. The primary endpoint was PFS by BIRC per mRECIST. As of Sep.13, 2025, 214 PFS events occurred and a preplanned IA was performed. **Results:** 423 pts (ECOG PS 1, 22.9%; AFP ≥400 ng/mL, 26.7%; portal vein invasion [vp1/2], 9.7%) were randomized to C+R+TACE (n=214) or TACE (n=209). As of data cutoff, median follow-up was 16.4 mo. Median PFS by BICR per mRECIST was significantly longer with C+R+TACE vs. TACE (11.1 vs. 8.3 mo; HR 0.73 [95% CI 0.56–0.96]; 1-sided p=0.0127). PFS by BICR per RECIST v1.1 (13.9 vs 9.5 mo; HR 0.67 [95% CI 0.50–0.91]) and by INV per mRECIST (13.8 vs 7.0 mo; HR 0.61 [95% CI 0.47–0.81]) and per REIST v1.1 (15.7 vs 8.4 mo; HR 0.61 [95% CI 0.45–0.81]) showed consistent findings (Table 1). PFS benefits with addition of C+R persisted across most prespecified subgroups. OS was not mature, with an early trend favoring C+R+TACE (HR 0.76 [95% CI 0.46–1.24]); OS was 91.4% vs 85.5% at 12 mo, and 82.0% vs 73.3% at 24 mo. Among treated pts, grade ≥3 TRAEs occurred in 73.7% (157/213) in C+R+TACE arm vs. 28.7% (60/209) in TACE arm; of them, the most common in C+R+TACE arm were increased AST (20.7% vs 12.9%), hypertension (19.7% vs 4.3%), increased ALT (17.8% vs 9.6%), and decreased platelet count (11.3% vs 2.9%). **Conclusions:** C+R+TACE provided statistically significant and clinically meaningful improvement in PFS vs TACE, with manageable safety, supporting this regimen as a potential new treatment option for TACE-eligible uHCC. Follow-up for OS is ongoing. Clinical trial information: NCT05320692. Research Sponsor: Jiangsu Hengrui Pharmaceuticals.

IMbrave251: Final analysis of atezolizumab (atezo) + lenvatinib (lenva) or sorafenib (sora) vs lenva or sora alone in locally advanced or metastatic hepatocellular carcinoma (LA/mHCC) previously treated with atezo and bevacizumab (bev). First Author: Arndt Vogel, Division of Gastroenterology and Hepatology, Toronto General Hospital, Medical Oncology, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada

Background: Several immuno-oncology therapies are available for 1L HCC, but data are limited after progression. IMbrave251 (NCT04770896) is the first global randomized Phase 3 trial to assess atezo + lenva or sora (TKIs) vs lenva or sora alone in patients (pts) with LA/mHCC that progressed after atezo + bev treatment (tx). This is the final analysis. **Methods:** Eligible pts had LA/mHCC that was responsive to atezo + bev tx but then progressed (atezo + bev was given for ≥4 cycles and ≥2 tumor assessments, of which ≥1 showed stable disease or complete/partial response). In the atezo + TKI arm, pts received atezo (1200 mg Q3W) + lenva (8 mg for pts < 60 kg or 12 mg for pts ≥60 kg QW) or sora (800 mg QW). Pts in the TKI-only arm received lenva or sora alone. The primary endpoint was OS. Secondary endpoints included PFS, ORR by RECIST 1.1, DOR, time to tumor progression (TTP), quality of life, and safety. Stratification factors were disease etiology (hepatitis B/C infection vs non-viral), ALBI score (1 vs 2/3), AFP (< 400 vs ≥400 ng/mL), and TKI therapy (lenva vs sora). **Results:** IMbrave251 enrolled 557 pts (full analysis population). Median duration of follow-up was 12 mo. Pts were assigned to receive atezo + TKI (n = 279) or TKI-only (n = 278). Most pts in both arms received lenva (92.1%) vs sora (7.9%). At clinical cutoff (Oct 10, 2025), median (m)OS with atezo + TKI vs TKI-only was 14.6 vs 12.5 mo (stratified HR 0.88; *P*= 0.2115) and mPFS was 4.3 vs 4.8 mo (stratified HR 1.05), respectively. Confirmed ORR was 7.5% vs 5.8% with atezo + TKI vs TKI-only. DOR was 10.2 vs 6.9 mo, respectively (stratified HR 0.47) (Table). Additional subgroup analyses and complete duration of systemic therapy will be shown. In the atezo + TKI vs TKI-only arm, the median tx duration was 5.6 vs 4.7 mo for lenva and 2.9 vs 2.3 mo for sora. No new or unexpected safety signals were seen (safety analysis n = 554; Table). **Conclusions:** IMbrave251 did not meet its primary OS endpoint but showed that the addition of atezo to TKIs had a manageable safety profile. This study provides clinically relevant Phase 3 evidence addressing an important, unanswered clinical question regarding 2L tx sequencing after immunotherapy and establishes a new OS benchmark for 2L tx in LA/mHCC. Clinical trial information: NCT04770896. Research Sponsor: F. Hoffmann-La Roche Ltd.

4003 **Oral Abstract Session**

First-line treatment of QLS31905 plus chemotherapy in patients with pancreatic cancer and gastric cancer: Data from a phase 1b/2 study. First Author: Xiaotian Zhang, Early Drug Development Center, Department of Gastrointestinal Oncology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital and Institute, Beijing, China

Background: QLS31905, a Claudin18.2/CD3 bispecific antibody, showed manageable safety and encouraging efficacy in Claudin18.2-positive patients (pts) with gastrointestinal tumors in a phase 1 trial. Here we report the safety and efficacy of QLS31905 plus chemotherapy in the first-line treatment of Claudin18.2-positive pts with pancreatic cancer (PC) and gastric cancer (GC). **Methods:** This phase 1b/2 trial recruited Claudin 18.2-positive (defined as ≥1% of tumor cells with ≥1+ staining intensity) pts with locally advanced unresectable or metastatic PC and GC who had not received systematic anti-tumor therapy. Pts with PC were administered QLS31905 at 350 μg/kg, 500 μg/kg, or 800 μg/kg Q2W or Q3W combined with gemcitabine plus nab-paclitaxel (Cohort 1). Pts with GC were administered QLS31905 at 500 μg/kg or 800 μg/kg Q3W combined with oxaliplatin plus capecitabine (Cohort 2). The primary endpoints were maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) in phase 1b and was objective response rate (ORR) in phase 2. **Results:** As of Dec 11, 2025, 88 pts with PC and 43 pts with GC were enrolled. No dose-limiting toxicity occurred. MTD was not reached. RP2D was determined as 800 μg/kg Q3W for both pts with PC and GC. Grade ≥3 treatment-related adverse events (TRAEs) occurred in 63 (71.6%) pts and 26 (60.5%) pts in Cohort 1 and Cohort 2, respectively. Ten pts (11.4%) in Cohort 1 and four pts (9.3%) in Cohort 2 discontinued any of the study treatment due to TRAEs. No QLS31905-related death occurred in both cohorts. In 82 efficacy-evaluable pts with PC, ORR and disease control rate (DCR) was 59.8% (95% confidence interval [CI], 48.34%-70.44%) and 89.0% (95% CI, 80.18%-94.86%), respectively. Median progression-free survival (PFS), duration of response (DoR), and overall survival (OS) was 8.74 months (95% CI, 7.16-10.71), 8.94 months (95% CI, 5.32-not evaluable [NE]), and 15.87 months (95% CI, 13.14-NE), respectively. In 15 pts with low Claudin18.2 expression in Cohort 1, ORR, DCR, median PFS, and median OS was 60.0% (95% CI, 32.29%-83.66%), 93.3% (95% CI, 68.05%-99.83%), 11.04 months (95% CI, 7.33-NE), and 15.61 months (95% CI, 3.98-NE), respectively. In 43 efficacy-evaluable pts with GC, ORR and DCR was 74.4% (95% CI, 58.83%-86.48%) and 93.0% (95% CI, 80.94%-98.54%), respectively. Median PFS and DoR was 10.09 months (95% CI, 6.87-NE) and not reached, respectively. In nine pts with low Claudin18.2 expression in Cohort 2, the ORR, DCR, median PFS, and 9-month PFS rate and was 77.8%, 100%, not reached, and 83.33%, respectively. **Conclusions:** QLS31905 plus chemotherapy in first-line treatment for Claudin18.2-positive pts with PC and GC showed manageable safety and potential efficacy. A phase 3 trial is ongoing to further confirm the efficacy and safety of QLS31905 in pts with PC. Clinical trial information: NCT06041035. Research Sponsor: Qilu Pharmaceutical Co., Ltd.

4004 **Oral Abstract Session**

A randomized phase II dose optimization study for alveltamig (ZG006), a trispecific T-cell engager targeting DLL3/DLL3/CD3, as monotherapy in patients with refractory neuroendocrine carcinoma (ZG006-003). First Author: Chuan Hua Zhao, Fifth Medical Center, Chinese PLA General Hospital, Beijing, China

Background: Alveltamig (ZG006) is an innovative trispecific T cell engager (Tri-TCE) targeting two distinct DLL3 epitopes on tumor cells and CD3 on T cells (DLL3/DLL3/CD3), designed to bridge tumor cells and T cells, thereby mediating T cell specific killing of tumor cells. Here we conducted a dose optimization study in refractory NEC. **Methods:** This is a randomized, multicenter, open-label phase 2 study evaluating ZG006 in NEC patients (pts) who failed at least one prior line of therapy. Pts were randomized 1:1 to receive ZG006 at either 10 mg or 30 mg every two weeks, following a priming dose of 1 mg. The primary endpoint is objective response rate (ORR) assessed by IRC per RECIST1.1. Results are reported for 64 pts who received at least one dose of ZG006. Biomarker based efficacy analyses were performed based on a threshold of ≥50% of tumor cells stained at any intensity for DLL3 with an investigational antibody against DLL3 (SP347, Roche Diagnostics). **Results:** As of Sep. 10, 2025, a total of 64 pts (32 at each dose group) were randomized and received at least one dose of ZG006. The median age was 56 years (range: 25-72), 35 (54.7%) were male. All pts had received ≥1 prior line of systemic therapy, with 65.6% had prior anti-PD-(L)1 treatment. The confirmed ORR in 10 mg and 30 mg groups were 21.9% (7/32) and 37.5% (12/32), respectively; Disease control rate (DCR) were 40.6% (13/32) and 62.5% (20/32), respectively. Among the 19 responders, primary tumor sites included cervix (8), gallbladder (4), stomach (3), rectum (3) and colon (1). Pts with ≥50% DLL3 staining in tumor cells had greater ORR, DCR, and progression-free survival (PFS). The confirmed ORR in 10 mg and 30 mg groups were 33.3% (6/18) and 56.3% (9/16), respectively; DCR were 50.0% (9/18) and 75.0% (12/16), respectively; With a median follow up of 6.4 months, median PFS were 3.02 and 8.41 months, respectively. Median DoR was not yet mature in both groups at data cut-off. Treatment-related adverse events (TRAEs) occurred in all pts. The most frequent events were pyrexia, cytokine release syndrome (CRS) and anaemia. Most CRS were Grade 1-2, with only four grade 3 CRS, resolved with supportive care. TRAEs led to treatment interruption in 15 pts (23.4%) and permanent discontinuation in 2 pts (3.1%, one in each dose group). No grade 5 TRAE. No significant difference was observed in the safety profile between these two dose groups. **Conclusions:** ZG006 demonstrated a robust and durable response and a manageable safety profile in previously treated NEC pts, with superior efficacy observed at the 30 mg dose. The confirmed ORR of 56.3% and median PFS of 8.41 months in pts with ≥50% DLL3 positive tumor cells are particularly encouraging, and support further development of ZG006 for this patient population at the 30 mg dose. Clinical trial information: NCT06440057. Research Sponsor: None.

4006 **Oral Abstract Session**

Nivolumab plus ipilimumab combined with chemotherapy as first-line treatment for HER2-negative unresectable advanced or recurrent gastric/gastroesophageal junction cancer: A randomized phase 3 trial (ATTRACTION-6). First Author: Do-Youn Oh, Seoul National University College of Medicine, Seoul, South Korea

Background: Anti-PD-1 antibodies combined with chemotherapy (Chemo) are established as a standard first-line (1L) treatment for HER2-negative gastric/gastroesophageal (G/GEJ) cancer. Nivolumab (NIVO) and ipilimumab (IPI), an anti-CTLA-4 antibody, have complementary mechanisms of action on tumor immunity. Combining NIVO plus Chemo with IPI is expected to suppress disease progression durably and prolong survival, as suggested in other types of tumors. **Methods:** ATTRACTION-6 is a randomized, phase 3 trial conducted in Japan, Korea, and Taiwan. Previously untreated patients with HER2-negative unresectable advanced or recurrent G/GEJ cancer were randomized 1:1 to receive NIVO 360 mg every 3 weeks, IPI 1 mg/kg every 6 weeks in addition to Chemo (S-1 plus oxaliplatin [SOX] or capecitabine plus oxaliplatin [CAPOX]) or Chemo alone. Randomization was stratified by PD-L1 (CPS≥5 or CPS < 5, indeterminate), ECOG PS (0 or 1), countries (Japan or Korea/Taiwan), and disease status (advanced or recurrent). Primary endpoint was overall survival (OS). Secondary endpoints included progression free survival (PFS), objective response rate (ORR) per RECIST v1.1 assessed by site investigator, and safety. **Results:** Between November 2021 and August 2023, 626 patients were randomized 1:1 to the NIVO + IPI + Chemo arm (N = 315) or the Chemo arm (N = 311). At the median follow-up of 31.3 months, the primary endpoint of OS was not met (HR 0.90; 95.8% CI 0.74-1.09; *P*= 0.267; median OS 15.7 vs 15.8 months). Median PFS was 8.9 vs 7.7 months (HR 0.83; 95% CI 0.69-1.00). Among patients with ≥1 measurable lesion at baseline, ORR was 57.9% vs 38.5%. Grade≥3 adverse events (AEs) and grade≥3 treatment-related AEs occurred in 80.0% and 64.8% in the NIVO + IPI + Chemo arm, respectively, and 62.4% and 42.9% in the Chemo arm, respectively. Treatment-related deaths occurred in 0.3% vs 0%, and the only observed event was gastroenteritis in the NIVO + IPI + Chemo arm. **Conclusions:** In ATTRACTION-6 study, NIVO + IPI + Chemo did not improve OS compared with Chemo as 1L treatment for patients with HER2-negative unresectable advanced or recurrent G/GEJ cancer. Although toxicity increased with the addition of NIVO and IPI, no new safety signals were observed. Clinical trial information: NCT05144854. Research Sponsor: Ono Pharmaceutical Co., Ltd.

4007 **Oral Abstract Session**

ONO-4578 combined with nivolumab (NIVO) and chemotherapy (chemo) as first-line (1L) treatment for patients with HER2-negative unresectable advanced or recurrent (adv/rec) gastric/gastroesophageal junction cancer (G/GEJ): A randomized, double-blind, phase 2 trial (ONO-4578-08). First Author: Sung Hee Lim, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: Anti-PD-1 antibodies combined with chemo are the standard 1L treatment for HER2-negative G/GEJ cancer. Prostaglandin E_2 (PGE_2)-EP4 signaling is known to induce immunosuppressive tumor microenvironment, by inducing the differentiation of MDSCs and M2 macrophages, potentially contributing to resistance to immunotherapy. ONO-4578, an EP4 antagonist, is expected to modulate tumor immunosuppression through inhibiting the PGE_2-EP4 signaling and to enhance the efficacy of anti-PD-1 antibody. The addition of ONO-4578 appeared to augment the efficacy of NIVO in patients with G/GEJ cancer in the previous phase 1 trial. This study aimed to evaluate the efficacy and safety of ONO-4578 combined with NIVO and chemo compared with placebo combined with NIVO and chemo as 1L treatment for patients with unresectable adv/rec G/GEJ cancer. **Methods:** ONO-4578-08 study is a randomized, double-blind, phase 2 trial conducted in Japan, Korea, and Taiwan. Chemo-naïve patients with HER2-negative adv/rec G/GEJ cancer were randomized in a 2:1 ratio (ONO-4578 group:placebo group), stratified by PD-L1 expression level (CPS < 5 vs CPS≥5), ECOG performance status (0 vs 1), presence of peritoneal metastasis (yes vs no). Patients in each group received ONO-4578 40 mg or placebo once daily, and all received NIVO 360 mg every 3 weeks and chemo (SOX [S-1 + oxaliplatin]/CAPOX [capecitabine + oxaliplatin]). The primary endpoint was investigator-assessed progression-free survival (PFS), powered (two-sided α = 0.10) to detect a HR of 0.65 with 117 events in a planned enrollment of 210 patients; secondary endpoints included overall survival (OS), objective response rate (ORR), and safety. **Results:** Between December 2023 and September 2024, 226 patients were randomized to each group (150 vs 76 patients). With a median follow-up of 8.5 months, PFS was significantly longer in the ONO-4578 group than the placebo group with a hazard ratio (HR) of 0.67 (90% confidence interval [CI]: 0.48–0.92; *P* = 0.040; median PFS: 9.0 vs 6.9 months). At a minimum follow-up of 7.4 months, OS favored the ONO-4578 group (median OS: not reached vs 12.7 months; HR: 0.60 [95% CI: 0.37–0.96]). ORR was also higher in the ONO-4578 group (62.0% vs 48.7%). The most common treatment-emergent adverse events (TEAEs) in the ONO-4578 group were diarrhea (55.7% vs 45.3%), anemia (55.0% vs 34.7%), and peripheral sensory neuropathy (50.3% vs 46.7%). Serious TEAEs occurred in 53.7% of patients in the ONO-4578 group and 42.7% in the placebo group. **Conclusions:** ONO-4578 combined with NIVO and chemo significantly improved PFS compared with placebo combined with NIVO and chemo in treatment-naive patients with HER2-negative unresectable adv/rec G/GEJ cancer with no new safety concerns. Clinical trial information: NCT06256328. Research Sponsor: Ono Pharmaceutical Co., Ltd.

Izalontamab brengitecan (iza-bren) versus chemotherapy in patients with recurrent or metastatic esophageal squamous cell carcinoma (ESCC): A multicenter, randomized, open-label, phase III study. First Author: Zhihao Lu, Peking University Cancer Hospital and Institute, Beijing, China

Background: Chemotherapy plus a PD-1/PD-L1 inhibitor is the standard first-line treatment for PD-L1 expressing advanced ESCC. However, most patients (pts) inevitably develop resistance to first-line therapy, and second-line chemotherapy shows an ORR of less than 10% and a median OS of less than 6 mo, highlighting the urgent need for novel therapeutics. Iza-bren is a potentially first-in-class ADC consisting of an EGFR-HER3 bispecific antibody conjugated to a potent topoisomerase I inhibitor Ed-04 via a cleavable linker. Iza-bren has shown promising clinical activity in previously treated ESCC pts in phase I study. Here, we present results from a phase III, randomized, open-label, multicenter study conducted in China evaluating the efficacy and safety of iza-bren versus chemotherapy as second line treatment for advanced ESCC. **Methods:** Pts with recurrent or metastatic ESCC who had progressed after first-line treatment with a PD-1/PD-L1 inhibitor plus platinum-based chemotherapy were randomized (1:1) to receive iza-bren (2.5 mg/kg at D1D8 Q3W) or physician's choice of chemotherapy (irinotecan, paclitaxel, or docetaxel Q3W). Dual primary endpoints were OS and PFS by Blinded Independent Central Review (BICR) per RECIST v1.1. **Results:** As of Oct 17, 2025, a total of 497 pts were randomized to iza-bren (n = 249) or chemotherapy (n = 248). Baseline characteristics were balanced between the two groups. At interim analysis, median follow-up for OS was 7.8 mo in the iza-bren group and 7.6 mo in the chemotherapy group. Iza-bren has demonstrated statistically significant and clinically meaningful improvement in both OS and PFS by BICR compared with chemotherapy. The median OS was 9.8 mo (95% CI, 7.9 to 11.0) with iza-bren and 7.2 mo (95% CI, 6.2 to 8.2) with chemotherapy (HR, 0.64; 95% CI, 0.49 to 0.83; P = 0.0004). The median PFS by BICR was 4.2 mo (95% CI, 3.6 to 4.5) with iza-bren and 2.0 mo (95% CI, 1.6 to 2.7) with chemotherapy (HR, 0.50; 95% CI, 0.40 to 0.63; P < 0.0001). ORR by BICR was 35.3% for iza-bren and 13.1% for chemotherapy. Grade≥3 TRAEs, which were predominantly hematologic in nature, occurred in 85.1% in the iza-bren group and 60.2% in the chemotherapy group. TRAEs leading to drug discontinuation were 2.0% in the iza-bren group and 3.3% in the chemotherapy group. TRAEs leading to death were 1.2% in the iza-bren group and 1.6% in the chemotherapy group. **Conclusions:** The study met both dual primary endpoints at prespecified interim analysis. Iza-bren demonstrated statistically significant and clinically meaningful improvements in OS and PFS compared with chemotherapy in pts with recurrent or metastatic ESCC who had progressed after first line PD-1/PD-L1 inhibitor plus platinum-based chemotherapy. The safety profile was manageable. The results support iza-bren as a new second-line standard of care for ESCC. Clinical trial information: NCT06304974. Research Sponsor: Baili-Bio (Chengdu) Pharmaceutical Co., Ltd.

4009 **Rapid Oral Abstract Session**

Neoadjuvant/adjuvant serplulimab vs. placebo combined with chemotherapy for PD-L1−positive gastric cancer: A randomized, double-blind, multicenter phase 3 study. First Author: Lin Shen, Department of Gastrointestinal Oncology, Peking University Cancer Hospital, Beijing, China

Background: The addition of immune checkpoint inhibitors (ICIs) to chemotherapy (chemo) in the neoadjuvant/adjuvant setting for gastric cancer (GC) has yielded mixed efficacy. Target population and treatment regimen remain to be optimized. This study compared the efficacy of serplulimab (anti-PD-1 antibody) plus chemo versus placebo plus chemo as neoadjuvant therapy and serplulimab versus chemo as adjuvant therapy for resectable GC. **Methods:** Patients with PD-L1 positive (PD-L1 CPS $\geq$ 5), histologically confirmed, untreated, resectable gastric or gastroesophageal junction (GEJ) adenocarcinoma were randomized 1:1 to receive 3 cycles of neoadjuvant intravenous (iv) serplulimab (4.5 mg/kg) or placebo, plus chemo (iv oxaliplatin, 130 mg/m^2 and oral S-1, 40-60 mg based on body surface area), followed by post-surgery adjuvant serplulimab monotherapy (up to 17 cycles) or adjuvant chemo (5 cycles), Q3W. The primary endpoint was investigator (INV)-assessed event-free survival (EFS). Efficacy superiority was first evaluated and established in patients with PD-L1 CPS $\geq$ 10 followed by that in the PD-L1 CPS $\geq$ 5 population. **Results:** Between November 26, 2019 and April 19, 2024, 588 patients were enrolled across 57 sites, with 292 randomized to the serplulimab group and 296 to the placebo group. As of the data cutoff date of August 19, 2025 with a median follow-up duration of 35.9 months, INV-assessed median EFS was significantly longer in the serplulimab group (n = 193) than in the placebo group (n = 217) in the PD-L1 CPS $\geq$ 10 population (not reached [NR], 95% CI 43.0−not estimable [NE] vs. 42.0 months, 95% CI 20.5−NE; HR 0.65, 95% CI 0.47−0.90; p = 0.0082), and in the PD-L1 CPS $\geq$ 5 population (NR, 95% CI 37.9−NE vs. 35.9 months, 95% CI 21.3−52.0; HR 0.73, 95% CI 0.56−0.94; p = 0.0152), meeting the protocol-specified superior criteria. Blinded independent central review-assessed median EFS was consistent with that of the investigator. Pathological complete response rate was higher in the serplulimab group than in the placebo group (21.6% vs 6.4%; odds ratio 3.95). Median OS was immature in both groups. Grade $\geq$ 3 treatment-related adverse events (TRAEs) were reported in 136 (46.6%) and 172 (58.5%) patients in the serplulimab and placebo groups, respectively. Discontinuation of any component of the study regimen due to TRAEs occurred in 19 (6.5%) and 31 (10.5%) patients in the respective groups. **Conclusions:** Neoadjuvant serplulimab plus chemo, followed by adjuvant serplulimab monotherapy, significantly prolonged EFS in patients with PD-L1-positive, resectable GC or GEJ adenocarcinoma. Improvements in other efficacy endpoints were also observed along with a favorable safety profile compared to neoadjuvant/adjuvant chemo. This world-first chemotherapy-free regimen (adjuvant) represents a promising treatment option for this indication. Clinical trial information: NCT04139135. Research Sponsor: Shanghai Henlius Biotech, Inc.

4010 **Rapid Oral Abstract Session**

Zanidatamab + chemotherapy (CT) ± tislelizumab for first-line (1L) HER2-positive (HER2+) locally advanced or metastatic gastroesophageal adenocarcinoma (mGEA): PD-L1 subgroup analysis from HERIZON-GEA-01. First Author: Sun Young Rha, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: In HERIZON-GEA-01 (NCT05152147), 1L zanidatamab + CT ± tislelizumab significantly improved progression-free survival (PFS) and, with tislelizumab, yielded a statistically significant overall survival (OS) benefit in HER2+ mGEA. Here we report efficacy in PD-L1 subgroups. **Methods:** Eligible patients (pts) with previously untreated HER2+ mGEA, irrespective of PD-L1 status, were randomized (1:1:1) to zanidatamab (1800 mg [<70 kg]/2400 mg [$\geq$70 kg] IV Q3W) + tislelizumab (200 mg IV Q3W) + capecitabine/oxaliplatin (CAPOX) or 5-FU/cisplatin (FP); zanidatamab + CAPOX or FP; or tras + CAPOX or FP. PD-L1 expression was retrospectively assessed using the VENTANA SP263 assay according to tumor area positivity (TAP) score and combined positive score (CPS). Primary endpoints were PFS (BICR) and OS; efficacy by PD-L1 status (TAP) was prespecified. **Results:** With 26 mo median follow-up, PFS (HR, 0.63; P <0.001) and OS (HR, 0.72; P = 0.004) were significantly prolonged with zanidatamab + tislelizumab + CT vs tras + CT in the ITT population. In pts treated with zanidatamab + tislelizumab + CT, similarly prolonged PFS and OS were observed in PD-L1−negative and PD-L1−positive pts (Table); data were consistent between TAP and CPS. In PD-L1 TAP <1% and $\geq$1% pts, the 18-mo PFS was 50.3% and 42.6%, respectively, and the 24-mo OS was 63.7% and 53.5% with zanidatamab + tislelizumab + CT. In the tras + CT arm, OS was prolonged in PD-L1−positive vs −negative pts. Of note, in the tras + CT arm, 15% of pts received subsequent checkpoint inhibitors and 29% received subsequent HER2-targeted therapies vs 2% and 13%, respectively, in the zanidatamab + tislelizumab + CT arm. Additional details on these subgroups will be presented at the congress. **Conclusions:** In HERIZON-GEA-01, zanidatamab + tislelizumab + CT demonstrated meaningful improvements in PFS and OS in both PD-L1−positive and PD-L1−negative pts as determined by TAP or CPS. The longer OS observed with tras + CT in PD-L1−positive vs −negative pts may be at least partially explained by differences in subsequent therapies. These findings are notable as they demonstrate benefit for this regimen regardless of PD-L1 status. Clinical trial information: NCT05152147. Research Sponsor: Jazz Pharmaceuticals; BeOne Medicines; Zymeworks Biopharmaceuticals.

A phase 2 pivotal study of savolitinib in patients with *MET*-amplified gastric cancer or gastroesophageal junction adenocarcinomas. First Author: Zhi Peng, Department of GI Oncology, Peking University Cancer Hospital & Institute, Beijing, China

Background: MET amplification is a poor prognosis for survival in patients (pts) with gastric cancer (GC) or gastroesophageal junction adenocarcinoma (GEJa). Currently no approved targeted therapy is available for MET-amplified GC/GEJa. Savolitinib is a potent and highly selective oral MET-TKI. Here we reported the primary analysis results from a pivotal phase 2 trial investigating savolitinib in MET-amplified GC/GEJa, conducted with registration intent (NCT04923932). **Methods:** Eligible pts had locally advanced or metastatic GC/GEJa with MET amplification (gene copy number $\geq$10 by FISH) and had failed $\geq$2 lines of prior standard therapy. Pts received savolitinib 200 mg (BW < 50 kg) or 300 mg (BW $\geq$50 kg) BID. The primary endpoint was ORR assessed by an Independent Review Committee (IRC) per RECIST 1.1, with a pre-specified efficacy threshold defined as the lower limit of the 95% CI of ORR exceeding 15%. Secondary endpoints mainly included DCR, DoR, TTR, PFS, OS and safety. An exploratory OS analysis was conducted in pts with MET-amplified GC/GEJa, who had previously received first-line, second-line, or later-line standard therapies, but were ineligible for study enrollment and did not receive the study drug. Plasma samples were also collected at baseline and end of treatment (EOT) for comprehensive genomic profiling using a 671-gene sequencing panel (Benrui GCP, OrigiMed). **Results:** As of Oct 8, 2025, 65 eligible pts were enrolled and received savolitinib. Baseline characteristics were: median age of 57.4 years, ECOG PS of 0 (13.8%) or 1 (86.2%), primary tumor sites of GC (84.6%) or GEJa (15.4%), and baseline ctDNA MET-positive rate of 64.6% (42 pts). Per the IRC assessment, ORR was 32.3% (95%CI: 21.2%, 45.1%), which exceeded the pre-specified efficacy threshold; in baseline ctDNA MET-positive pts (42 pts), IRC-assessed ORR was 45.2% (95%CI: 29.8%, 61.3%). IRC-assessed secondary efficacy endpoints were: DCR of 63.1%; mTTR of 1.4 months; mDoR of 9.7 months; and mPFS 4.0 of months. mOS was 6.9 months in the 65 treated pts, versus 4.8 months in 139 pts who received alternative treatments rather than the study drug in the exploratory OS analysis. Savolitinib-related TEAEs of Grade $\geq$3 occurred in 23 pts (35.4%). Exploratory ctDNA biomarker analysis showed that pts (N = 14) harboring baseline alterations in FGFR2, EGFR, PIK3CA, BRAF, or KRAS had lower ORR (14.3%, 2/14) and shorter mPFS (1.4 months). Additionally, in pts (N = 26) who provided PD/EOT samples, 12 pts developed alterations in these genes that were identified as putative acquired resistance mechanisms, and 4 pts had acquired MET mutations. **Conclusions:** Savolitinib showed clinical efficacy and a tolerable safety profile in pts with MET-amplified GC/GEJa who had received $\geq$2 lines of prior therapy, supporting it to be a future treatment option for this genetically defined population. Clinical trial information: NCT04923932. Research Sponsor: HUTCHMED Limited; AstraZeneca.

4012 **Rapid Oral Abstract Session**

Randomized phase II trial of olaparib and pembrolizumab vs olaparib alone as maintenance therapy in metastatic pancreatic cancer patients with germline BRCA1 or BRCA2 (gBRCA1/2) mutations: SWOG S2001. First Author: Vincent Chung, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: Preclinical studies have demonstrated that PARP inhibitors modulate the immune microenvironment by increasing genomic instability, PD-L1 expression and activating the immune inflammatory stimulator of interferon genes (STING) pathway. The POLAR trial demonstrated promising results combining pembrolizumab with olaparib as maintenance therapy in patients (pts) with homologous recombination deficiency (HRD) mutations. S2001 is a randomized phase II trial evaluating the addition of pembrolizumab to olaparib as maintenance therapy in patients with gBRCA1/2. **Methods:** Eligible pts had mPDA with gBRCA1/2 mutations and had received a minimum of 4 months of platinum-based chemotherapy without progression. Pts were randomized 1:1 to olaparib 300 mg twice per day plus pembrolizumab 200 mg every 3 weeks or olaparib alone. The primary endpoint was progression-free survival (PFS) with a target hazard ratio (HR) of 0.6 (median PFS 7.0 vs 11.7 months) with 1-sided alpha=0.1 and 80% power. Secondary outcomes were safety and tolerability, overall survival (OS), overall response rate (ORR), and disease control rate (DCR). The accrual goal was 88 pts to have 78 eligible for analysis. Differences in PFS by treatment arm were assessed via stratified log-rank test, with first line platinum-based chemotherapy, Zubrod PS, and disease status after first line treatment as stratification factors. Tissue and blood samples for correlative studies were banked. **Results:** The study enrolled 73 patients, with 68 eligible, and was closed for futility after a planned interim analysis showed that PFS was not improved in the pembrolizumab + olaparib arm (p=0.82), despite higher ORR (p=0.20) (Table). Treatment was well tolerated, with no grade 4-5 treatment-related adverse events and similar toxicity profiles across arms. Autoimmune toxicities on the experimental arm included adrenal insufficiency, hyperthyroidism, and hypothyroidism. Grade 3 adverse events in both arms included neutropenia, anemia, thrombocytopenia, gastrointestinal toxicity and fatigue. **Conclusions:** S2001 is the first randomized controlled trial evaluating the addition of pembrolizumab to olaparib in pancreas cancer. Despite doubling the ORR and improvement in DCR and PFS in the experimental arm, the high bar of improving PFS to 11.7 months was not met. Activity seen in the experimental arm of S2001 is comparable to the HRD cohort of the POLAR trial which demonstrated ORR 35%, DCR 90% and PFS of 8.2 months. Further follow-up for mature survival outcomes and translational analysis of DNA and RNA are planned. Funding: NIH/NCI/NCTN grants U10CA180888, U10CA180819 with additional support from by Merck & Co, Inc. Clinical trial information: NCT04548752. Research Sponsor: NIH/NCI/NCTN grants; U10CA180819; Merck & Co., Inc.

	Pembrolizumab + Olaparib (n=34)	Olaparib (n=34)
Median PFS	8.2 months	6.4 months
Median OS	20.0 months	22.1 months
ORR	28.1%	14.3%
DCR	84.4%	64.3%

Results from a phase 2a study of atebimetinib in combination with mGnP in advanced or metastatic pancreatic cancer. First Author: Vincent Chung, Department of Medical Oncology and Therapeutics Research, City of Hope, Duarte, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) is driven predominantly by oncogenic KRAS signaling, yet prior attempts to target the MAPK pathway have been limited by toxicity and emergence of resistance. Atebimetinib is a next-generation, deep cyclic inhibitor (DCI) of MEK designed to achieve pulsatile pathway inhibition with improved tolerability. We report a Phase 2a cohort evaluating atebimetinib in combination with modified gemcitabine/nab-paclitaxel (mGnP) in the first-line treatment of advanced or metastatic PDAC (NCT05585320). **Methods:** In this multicenter, open-label, nonrandomized Phase 2a study, patients with previously untreated advanced or metastatic PDAC were eligible for participation and were treated with orally administered atebimetinib daily in combination with mGnP (modification: every other week dosing). The primary endpoint was objective response rate (ORR) per investigator assessment using RECIST 1.1 criteria in response-evaluable patients. The cohort was powered (~80%, one sided alpha 0.05) using an optimal Simon's 2-stage design. **Results:** Fifty-five patients were enrolled and treated with 320 mg atebimetinib daily + mGnP. ECOG performance status was 0-1 (100%); median age was 68 years (range 42-85 years), 62% were ≥65 years, and 55% were male. No grade 5 treatment-related adverse events (AE) were observed. No AE related to atebimetinib were higher than grade 3. Grade 3 AE related to atebimetinib occurred in 29% of participants, with the most frequent being rash (5%), ALT increased (5%), and AST increased (5%). Among the 50 response-evaluable patients, best overall response (BOR) achieved were 21 PR, 21 SD, 7 PD, 1 NE. The ORR was 42%, and DCR was 84%. With a median follow-up of 10.4 months (data cutoff Jan 7, 2026), 6- and 9-month OS rates were 88% and 79%, respectively; median PFS was 8.3 months and median OS was not reached. **Conclusions:** Atebimetinib in combination with mGnP demonstrated favorable safety and promising efficacy compared to historic standard-of-care (SoC) GnP.[1] A phase 3 registrational trial is planned to start in mid-2026 for evaluation of atebimetinib + mGnP versus SoC GnP. 1. Nilvanstomig (ZG005), an anti-PD-1/TIGIT bispecific antibody, plus bevacizumab vs. sintilimab plus bevacizumab biosimilar as first-line therapy for advanced hepatocellular carcinoma: A randomized, multi-center, phase II trial. First Author: Hong Wu, Department of General Surgery/Liver Transplant Center, West China Hospital, Sichuan University, Chengdu, China

Background: Checkpoint inhibitors combined with anti-angiogenic therapy represents one of the standard first-line therapies for advanced hepatocellular carcinoma (aHCC). Nilvanstomig (ZG005) is a recombinant humanized anti-PD-1/TIGIT bispecific antibody. By blocking both pathways, it can synergistically activate T cells and enhance the anti-tumor activity of NK cells. This study evaluated ZG005 plus bevacizumab vs. sintilimab plus IBI305 (a bevacizumab biosimilar) as first-line therapy for aHCC. **Methods:** In this randomized, open-label, multicenter, phase 2 trial conducted in China, patients with aHCC who had not previously received systemic treatment were randomly assigned (1:1:1) to receive ZG005 10 mg/kg plus bevacizumab 15 mg/kg (Arm A); ZG005 20 mg/kg plus bevacizumab 15 mg/kg (Arm B); or sintilimab 200 mg plus IBI305 15 mg/kg (Arm C). All treatments were administered intravenously every 3 weeks until disease progression or unacceptable toxicity. Randomization was stratified by baseline AFP level (< 400 vs. ≥400 ng/mL), macrovascular invasion or extrahepatic metastasis (presence vs. absence). The primary endpoint was IRC-assessed PFS per RECIST v1.1, with key secondary endpoints including PFS per mRECIST, ORR and DCR by both criteria, and OS. **Results:** As of the data cutoff (Nov 25, 2025), 95 patients were enrolled and received at least one dose of treatment (Arm A, n = 31; Arm B, n = 32; Arm C, n = 32). Baseline characteristics were well-balanced across the treatment arms. For all patients enrolled, the median age was 61 years (range, 37-75), with 85.3% of patients being male. Disease characteristics included BCLC stage B (28.4%) or C (71.6%), Child-Pugh score A5 (83.2%) or A6 (16.8%), baseline AFP ≥400 ng/mL in 45.3% of patients, and HBV positivity in 73.7%. Macrovascular invasion and/or extrahepatic metastasis were present in 71.6% (68/95) of patients. With a median follow-up of about 5 months, the IRC-assessed ORR was 32.3% in Arm A, 37.5% in Arm B, and 25.0% in Arm C per RECIST v1.1; the corresponding ORRs per mRECIST were 54.8%, 50.0%, and 34.4%. The IRC-assessed median PFS per RECIST v1.1 was not reached in Arm A or B, compared with 5.8 months in Arm C (Arm A vs. C: HR 0.40, 95% CI 0.15-1.05; Arm B vs. C: HR 0.28, 95% CI 0.10-0.79). The safety profiles were comparable across the three arms. No grade ≥3 hemorrhagic adverse events were reported in either Arm A or B. **Conclusions:** The combination of ZG005 and bevacizumab as first-line treatment in patients with aHCC demonstrated an early encouraging efficacy with an acceptable safety profile. Higher response rates and prolonged PFS were observed with the ZG005-based regimens. Longer follow up of the current study and future phase 3 trials are warranted to validate the efficacy and safety of ZG005 in combination with bevacizumab in aHCC. Clinical trial information: NCT06558227. Research Sponsor: Suzhou Zelgen Biopharmaceuticals Co.,Ltd.

Tegavivint, a downstream Wnt/β-catenin inhibitor: Dose-finding results from a phase 1/2 trial in advanced hepatocellular carcinoma (aHCC). First Author: David Hsieh, Gastrointestinal Medical Oncology, UT Southwestern Medical Center, Dallas, TX

Background: Wnt/β-catenin pathway activation is a hallmark of many cancers, with Wnt pathway mutations (WPMs) present in ~40% of advanced HCC (aHCC). Tegavivint is a first-in-class small-molecule inhibitor of TBL1, a transcriptional co-factor required for nuclear β-catenin–dependent oncogenic gene expression. Binding of TBL1 by tegavivint disrupts the TBL1/β-catenin complex, resulting in selective degradation of nuclear β-catenin while preserving cytoplasmic and membrane-bound β-catenin functions associated with normal tissue homeostasis. This mechanism inhibits Wnt-driven oncogenicity while avoiding toxicities observed with upstream Wnt inhibitors. Here, we report dose-finding results from an ongoing phase 1/2 study of tegavivint in aHCC (NCT05797805). **Methods:** This multicenter, open-label phase 1/2 study employs a 3+3 dose-escalation design with backfill, followed by dose optimization. Eligible patients (pts) had aHCC previously treated with ≥1 systemic therapy, BCLC stage C or B disease not amenable to locoregional therapy, and Child-Pugh class A or B (score ≤ 7). WPM status was assessed by liquid biopsy. Tegavivint was administered intravenously once weekly. Primary objectives were safety and tolerability; secondary objectives included preliminary efficacy and PK/PD. **Results:** As of 21 Jan 2026, 39 pts were enrolled (median age 68 years [range 34–84]); 28 had WPMs, and the median number of prior systemic therapies was 2 (range 1–6). Pts were treated across four dose levels (3–8 mg/kg), demonstrating dose-proportional increases in exposure. At 8 mg/kg, 2 of 5 pts experienced Grade 3 anemia within the DLT window, establishing 3–6.5 mg/kg as the recommended dose range (RDR). Across all doses, the most common (all grade/grade ≥ 3; n/n) TRAEs were fatigue (9/0), hyperbilirubinemia (7/4; isolated, asymptomatic and reversible), anemia (5/5; reversible), myalgia (4/0), and decreased appetite (4/0). Among WPM pts evaluable for efficacy within the RDR (n = 18), those with ≤ 3 previous lines of therapy (n = 9) achieved an overall response rate (ORR) of 22%, disease control rate (DCR) of 89%, and median progression-free survival (mPFS) of 8 mo, compared with 0% ORR, 56% DCR, and 4 mo mPFS in pts treated in later lines (n = 9). No significant clinical benefit was observed in pts without WPMs. Pts remaining on treatment for ≥ 4 months (n = 9) demonstrated concordant improvements in liver enzymes, alpha-fetoprotein, platelet counts, and/or ctDNA variant allele frequency. **Conclusions:** Tegavivint is the first Wnt/β-catenin inhibitor to demonstrate monotherapy clinical activity and a manageable safety profile in heavily pretreated aHCC pts with WPMs. Observed partial responses, durable disease control, and on-target PD effects in 2L and 3L pts support further development of tegavivint as a monotherapy or in combination with other treatments for this population. Clinical trial information: NCT05797805. Research Sponsor: Iterion Therapeutics.

A phase Ib/II trial of first-line trastuzumab, nivolumab, gemcitabine, and cisplatin in HER2-positive biliary tract cancer (HERBOT): A multi-institutional study from the Korean Cancer Study Group. First Author: Choong-kun Lee, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: Several phase II trials support HER2 as a promising actionable target in advanced biliary tract cancers (BTCs). However, the efficacy of adding anti-HER2 therapy to the current first-line standard-of-care (ICI plus gemcitabine/cisplatin [GemCis]) remains unknown. We report the results of the HERBOT trial evaluating this quadruplet combination. **Methods:** This multi-institutional, open-label, phase Ib/II study (KCSG-HB23-05; NCT05749900) enrolled treatment-naïve pts with locally advanced/unresectable or metastatic, HER2-positive BTC (defined as centrally confirmed HER2 IHC3+, or IHC2+/ISH+, or *ERBB2* gene copy number ≥6.0 by NGS). Pts received trastuzumab 6mg/kg (after 8mg/kg load) D1, nivolumab 360mg D1, cisplatin 25mg/m^2 D1,8, and gemcitabine 1000mg/m^2 (dose level 0) or 800mg/m^2 (dose level -1) D1,8 every 3 weeks. The primary endpoints were recommended phase II dose (RP2D, phase Ib) and ORR per RECIST v1.1 (phase II). Secondary endpoints included PFS, DCR, OS, safety. Exploratory biomarker analyses included AI-powered whole-slide image (WSI) profiling of HER2 expression and immune phenotype assessment. **Results:** Dose level 0 was established as RP2D with no DLT. Among total of 40 pts, 29 (72.5%) had gallbladder cancer and 26 (62.5%) were HER2 IHC 3+. The primary endpoint was met with an ORR of 55% (95%CI: 38.5 – 70.7; 1 CR, 21 PR) and a DCR of 95% (95%CI: 83.5 – 99.4); median duration of response was 12.6 months (95%CI: 5.7 – NR). With a median follow-up of 17.0 months, median PFS was 10.6 months (95%CI: 7.8 – 17.4) and median OS was not yet reached. Three pts (7.5%) underwent curative-intent conversion surgery. Pts with HER2 IHC 3+ showed a numerically longer PFS compared to IHC 2+/ISH+ (17.4 vs 9.7 months; HR 0.46, 95%CI: 0.20 – 1.07). Common grade ≥3 treatment-related adverse events (TRAEs) included neutropenia (57.5%), anemia (30.0%), and thrombocytopenia (22.5 %). A grade 2 decreased ejection fraction occurred in 1 pt (2.5%); no grade ≥3 immune-related AEs were observed. AI-based WSI analyses revealed that ≥10% HER2 3+ tumor cells proportion was associated with higher ORR (80% vs 36.4%, P = 0.009) and numerically superior PFS (17.4 vs 9.1 months; HR 0.54, 95%CI: 0.23 – 1.28). Pts with inflamed immune phenotype (n = 4) showed durable responses (ORR 75%; mPFS and mOS NR). **Conclusions:** The HERBOT trial demonstrates that adding trastuzumab to first-line ICI plus GemCis provides robust antitumor activity and manageable safety in HER2-positive BTC. This study is the first to report the efficacy of a HER2-targeted quadruplet regimen in the first-line setting, providing strong clinical rationale for integrating HER2-targeted strategies into first-line treatment and complementing ongoing global phase III trials in this molecularly defined subgroup. Clinical trial information: NCT05749900. Research Sponsor: Korean Cancer Study Group; Boryung Corp; ONO/BMS.

4017 **Rapid Oral Abstract Session**

Pemigatinib for untreated unresectable/metastatic cholangiocarcinoma (mCCA) with fibroblast growth factor receptor-2 (FGFR2) rearrangement: Phase 3 FIGHT-302 results. First Author: Tanios S. Bekaii-Saab, Division of Hematology/Oncology Mayo Clinic Arizona, Phoenix, AZ

Background: First-line mCCA treatment is chemotherapy and immunotherapy. Based on the phase 2 FIGHT-202 trial, pemigatinib was the first FGFR1-3 inhibitor approved in second line and beyond for mCCA with *FGFR2* rearrangement. Results from the phase 3, randomized, global FIGHT-302 trial evaluating pemigatinib as first-line therapy are reported here (NCT03656536). **Methods:** Patients (pts) aged ≥18 y with previously untreated mCCA with *FGFR2* rearrangement were randomized 1:1 to receive oral pemigatinib (13.5 mg once daily q21) or intravenous chemotherapy (1000 mg/m^2 gemcitabine + 25 mg/m^2 cisplatin d1,8 q21 ≤8 cycles) stratified by previous receipt of 1 chemotherapy cycle, geographic region, and tumor burden. Pemigatinib crossover was allowed for control arm pts progressing on chemotherapy. Primary end point was progression-free survival (PFS). Secondary efficacy, safety, and exploratory end points were also analyzed. **Results:** After prescreening >4000 pts, only 196 had *FGFR2* rearrangement and were screened; 167 were randomized to receive pemigatinib (n=83) or chemotherapy (n=84) before closing the study early due to slow accrual. Baseline characteristics and demographics were similar between arms. Median PFS (mPFS) with pemigatinib versus chemotherapy was 8.3 versus 6.8 mo, respectively (hazard ratio [95% CI], 0.58 [0.39-0.87]; nominal *P*=.0078); secondary efficacy endpoints generally supported primary results (Table). Median OS was similar, although these results are confounded by FGFR inhibitor administration as second-line treatment. In the crossover group (n=42, second-line pemigatinib), mPFS was 8.1 mo. Safety was consistent with previous results (Table). Exploratory analyses of genetic co-alterations associated with treatment response will be presented. **Conclusions:** FIGHT-302 was the first phase 3 trial of a targeted therapy for untreated mCCA. Pemigatinib demonstrated superior activity and prolonged mPFS compared with first-line chemotherapy. The results confirm the current management paradigm of pemigatinib administration after disease progression on chemotherapy. Clinical trial information: NCT03656536. Research Sponsor: Incyte Corporation; N/A.

H&E 2.0: Artificial intelligence–driven prediction of N256-glycosylated CEACAM5/6 expression in esophageal and gastric adenocarcinomas. First Author: Felicia Wee, Institute of Molecular and Cell Biology (IMCB), Agency for Science, Technology and Research (A*STAR), Singapore, Singapore

Background: The antibody-drug conjugate (ADC) EBC-129 has shown promising clinical responses in a Phase 1A/B trial, where higher H-scores correlate with responses, slated to start Phase 2. It specifically targets N256-glycosylated CEACAM5/6, highly expressed on solid tumours, including gastro-oesophageal adenocarcinomas. Recent advances in deep learning enabled the extraction of morphological features from stained pathological images to predict protein expression from haematoxylin and eosin (H&E) images. We investigated the feasibility of training deep learning models on H&E images of gastro-oesophageal carcinomas and assessed the models' ability to predict EBC-129 antigen (Ag) expression directly from H&E images. **Methods:** H&E and immunohistochemistry (IHC) images from same sections of oesophageal and gastric adenocarcinoma TMA tissues (n = 103 cores) were acquired at the same magnification. Tumour and EBC-positive areas were annotated in FIJI, with images preprocessed in Python to obtain 112x112-pixel H&E image patches. Cell patches with tumour$^+$EBC$^+$ labels were classified positive while patches with all other labels were classified negative. Six cores were held-out for testing while class balancing was conducted for the remaining 97 cores, where image patches were split 80:20 for training and validation respectively. Deep learning prediction of Ag was tested using two model architectures (DenseNet121 and ResNet50 - with no pre-trained weights) employing k-fold cross validation (k = 5). Performance metrics were recorded for the best model of each split, with mean and standard deviation values tabulated across 5 splits to determine the best performing model architecture family, followed by core-level metrics to determine the best performing individual model. **Results:** Feasibility and predictive potential of deep learning models was demonstrated, with superior performance metrics exhibited by the DenseNet121 model. It outperformed ResNet50 across all metrics for the combined held-out test set: AUC (0.796 ± 0.092 vs 0.748 ± 0.105), balanced accuracy (0.727 ± 0.075 vs 0.664 ± 0.100), F1 score (0.756 ± 0.059 vs 0.742 ± 0.070) and AUPRC (0.426 ± 0.132 vs 0.404 ± 0.157). Friedman test and post-hoc Conover's test revealed significant ($p < 0.05$) differences in metrics amongst the 10 models, where subsequent rank sum of mean metric values showed that DenseNet121 fold2_epoch09 performed best across the held-out test cores, displaying robustness and generalisability. **Conclusions:** There is potential of deep learning models to predict EBC-129 Ag expression from H&E images and suggest possible triaging of patients suitable for treatment. Immediate next steps include examining virtual stain plots for comparison to ground truth IHC images. Future work will extend to pancreatic ductal adenocarcinoma, building on encouraging findings from the Phase 1 trial. A machine learning algorithm for optimizing treatment selection for patients with up to three hepatocellular carcinomas measuring ≤ 3 cm. First Author: Takashi Kokudo, National Center for Global Health and Medicine, Tokyo, Japan

Background: Liver resection (LR) and radiofrequency ablation (RFA) are recommended for patients with early-stage hepatocellular carcinoma (HCC) with three nodules measuring ≤3 cm and preserved liver function. This study aimed to develop a predictive model to guide treatment decisions based on survival outcomes. **Methods:** This study included 18,958 patients with up to three HCCs measuring ≤3 cm from the nationwide survey of Japan. The Recurrent Deep Survival Machines (RDSM) model was employed for deep survival analysis. We employed 10-fold cross-validation, the concordance index (C-index), and overall survival (OS) to assess model performance. Survival curves were compared using the log-rank test. To identify potential confounding factors, 1:1 propensity score matching (PSM) was performed. **Results:** Patients undergoing LR demonstrated significantly longer OS than those receiving RFA (5-year survival rate 81.4% vs. 73.1%; $P < 0.005$). The trained RDSM model achieved a C-index of 0.68. In the deep learning (DL) model, patients undergoing recommended treatment demonstrated significantly longer survival than those who did not (5-year survival rate 81.2% vs. 73.9%; $P < 0.005$; PSM, 81.9% vs. 76.7%; $P < 0.005$). The DL modeling recommended LR in 6,966 (84.5%) patients undergoing RFA, especially those showing typical imaging patterns (early enhancement and washout in the computed tomography images [85.9% vs. 61.7% and 84.1 vs.74.3%, respectively]). **Conclusions:** DL modeling effectively helped treatment allocation for patients with up to three HCCs measuring ≤3 cm. Our study indicates the potential utilization of DL modeling in the treatment allocation of patients with up to three HCCs measuring ≤3 cm. Research Sponsor: Small Business Innovation Research.

Multi-modal AI modeling to predict clinical trial outcomes and benchmarks pan-RAS versus KRAS G12D inhibition in KRAS G12D–mutant PDAC. First Author: Marc Robert de Massy, Orakl Oncology, LE Kremlin-Bicetre, France

Background: In pancreatic ductal adenocarcinoma (PDAC), uncertainty persists regarding the optimal positioning of pan-RAS inhibitors, allele-specific KRAS inhibitors, and chemotherapy backbones. While patient-derived organoids (PDOs) provide functional resolution of drug response, their clinical utility has been limited by cohort size and insufficient validation against trial outcomes. **Methods:** A biobank of 135 colorectal cancer (CRC) and PDAC PDOs was assembled with matched clinical annotation, omics characterization, and functional drug profiling. Multi-modal AI models integrating molecular features, PDO drug response, and clinical covariates were trained to predict patient-level progression-free survival (PFS) and longitudinal response, and to aggregate these predictions into cohort-level clinical trial outcomes. Model performance was evaluated by benchmarking predicted outcomes against published results across 22 treatment arms from multiple clinical trials. A pan-RAS inhibitor (daraxonrasib), a KRAS G12D-directed inhibitor (zoldonrasib), and FOLFIRINOX (FFX) were compared as single agents or in combination in a KRAS G12D-mutant PDAC subset (n = 23), with external benchmarking to published clinical data. **Results:** The AI models demonstrated robust predictive performance at both the patient and cohort levels. Patient-level predictions were driven by functional PDO drug response and established clinical factors, including performance status and prior treatment exposure. At the cohort level, predicted and published outcomes showed good agreement (R^2 = 0.63), with correct ranking of treatment arms by efficacy in 78% of cases. In pairwise arm-to-arm comparisons, the model identified the superior regimen in 80% of comparisons. When applied to KRAS G12D-mutant PDAC, virtual clinical trial simulations preserved the relative efficacy hierarchy observed in external datasets. Zoldonrasib showed heterogeneous predicted activity (simulated ORR 20% vs reported 30%), whereas daraxonrasib demonstrated more favorable predicted outcomes (simulated ORR 35% vs reported 36%). Combination with FFX further improved predicted efficacy for zoldonrasib, particularly in first-line simulations (simulated ORR 38% vs reported 63%). **Conclusions:** Multi-modal AI modeling trained on clinically annotated PDO collections enables calibrated simulation of clinical trial outcomes and comparative assessment of therapeutic strategies in KRAS-mutant PDAC. By capturing patient-level heterogeneity and cohort-level efficacy trends, this framework provides a scalable decision-support tool for arm selection, therapeutic positioning, and trial design in KRAS-directed drug development. Benchmarking the KEYNOTE-811 standard of care using AI-reconstructed external control arms in advanced gastric cancer. First Author: Augustine Annan, NouStarX, Westport, CT

Background: Randomized controlled trials in rare cancers and biomarker-enriched populations face significant recruitment burdens. External control arms (ECA) derived from historical Individual Patient Data (IPD) can mitigate these challenges, yet cross-trial heterogeneity often confounds comparisons. This study evaluates the feasibility of an AI-powered pipeline to reconstruct IPD from historical HER2+ advanced gastroesophageal adenocarcinoma trials and validates the cohort against a modern standard-of-care benchmark (KEYNOTE-811). **Methods:** An LLM-computer vision pipeline digitized KM curves from 10 historical trials (2011–2022) and the KEYNOTE-811 control arm (2023). IPD was reconstructed using a modified Guyot algorithm with risk-table guidance and least-squares optimization. Accuracy was validated against published HR and median survival. A propensity score matched (PSM) analysis (1:1 nearest-neighbor) compared the KEYNOTE-811 control arm (n=348) to historical controls (n=395). Sensitivity analyses addressed geographic imbalance (34% vs. 95% Asian) and early-period confounding via 3- and 6-month landmarking. **Results:** Technical validation demonstrated high fidelity: median OS concordance was 100%, with a reconstructed-to-published OS HR delta of only 0.01 (0.85 vs 0.84). The initial PSM suggested significantly worse outcomes for the KEYNOTE-811 control (OS HR 1.69, $p<0.0001$). However, this discrepancy was primarily driven by regional heterogeneity. After region-specific matching, OS HR stabilized at 1.13 (p=0.40). A 6-month landmark analysis further resolved early-period bias, achieving statistical equivalence for OS (HR 1.26, p=0.057) and PFS (HR 0.97, p=0.84). Residual imbalances in ECOG (SMD 0.25) and primary site (SMD 0.32) persisted but did not negate the trend toward equivalence. **Conclusions:** AI-powered IPD reconstruction achieves high fidelity to original trial data. While naive pooled ECAs may display era-specific survival artifacts, rigorous causal inference frameworks can resolve cross-trial heterogeneity. This study confirms that AI-reconstructed ECAs are viable tools for benchmarking novel therapies when paired with robust methodological guardrails for regional and baseline covariate alignment. Research Sponsor: None.

First-line (1L) trastuzumab deruxtecan (T-DXd)—based regimens in advanced HER2-expressing gastric cancer (GC), gastroesophageal junction adenocarcinoma (GEJA), or esophageal adenocarcinoma (EA): Safety results from DESTINY-Gastric03 (DG-03) Part 2 arms D and F, and Part 4. First Author: Yelena Y. Janjigian, Gastrointestinal Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

Background: T-DXd 6.4 mg/kg monotherapy is approved in several countries for advanced HER2+ (IHC 3+ or IHC 2+/ISH+) GC/GEJA after an indicated HER2-directed regimen. Early data have shown promising antitumor activity with 1L T-DXd + immunotherapy + chemotherapy for advanced HER2+ GCs. Here, we report an approximate time-matched analysis of safety results for DG-03 Part 2 arms D and F, and Part 4. **Methods:** DG-03 (NCT04379596) is a Phase 1b/2, open-label, multipart trial. Part 2 (arms A–F) enrolled patients (pts) with previously untreated advanced HER2+ (IHC 3+ or IHC 2+/ISH+) GC/GEJA/EA. Pts in arm D received T-DXd 6.4 mg/kg + pembrolizumab (pembro) + fluoropyrimidine (FP; 5-fluorouracil or capecitabine), and pts in arm F received T-DXd 5.4 mg/kg + pembro + FP. In Part 4, pts with previously untreated advanced HER2-expressing (IHC 3+, IHC 2+/ISH+, IHC 2+/ISH−, or IHC 1+) GC/GEJA/EA were enrolled and received T-DXd 5.4 mg/kg + rilvegostomig (rilve; a monovalent, Fc-reduced, bispecific IgG1 antibody against PD-1 and TIGIT receptors) + FP. HER2 status was based on local testing. Secondary endpoints included frequency of adverse events (AEs) and serious AEs. **Results:** As of Feb 15, 2023, Aug 19, 2024, and Oct 16, 2025, 43, 32, and 62 pts received treatment (Tx) in Part 2 arm D, Part 2 arm F, and in Part 4, respectively. Median (range) total duration of Tx for both T-DXd and pembro was 6.1 (0.5–13.3) months (mo) in Part 2 arm D, and 6.9 (0.7–10.3) mo for T-DXd and 7.5 (0.7–10.3) mo for pembro in Part 2 arm F. Median (range) total duration of Tx for both T-DXd and rilve was 6.5 (0.7–14.7) mo in Part 4. A summary of safety data is shown in the Table. Drug-related adjudicated interstitial lung disease (ILD)/pneumonitis events occurred in 2 pts (5%) in Part 2 arm D, no pts in Part 2 arm F, and 2 pts (3%) in Part 4. **Conclusions:** Results with T-DXd (5.4 mg/kg)—based regimens were generally consistent with the known safety profiles of each agent; no new signals were observed. Safety data support use of pembro/rilve as combination partners for T-DXd (5.4 mg/kg) in advanced HER2-expressing GCs. Clinical trial information: NCT04379596. Research Sponsor: AstraZeneca.

Sonesitatug vedotin (Sone-Ve) monotherapy in patients (pts) with claudin 18.2–positive (CLDN18.2+) advanced or metastatic gastric or gastroesophageal junction (GEJ) cancers: Data from CLARITY-PanTumor01. First Author: Kohei Shitara, National Cancer Center Hospital East, Kashiwa, Japan

Background: Sone-Ve (AZD0901), an antibody-drug conjugate comprising an anti-CLDN18.2 antibody and monomethyl auristatin E, showed promising antitumor activity and a manageable safety profile in pts with advanced or metastatic gastric/GEJ cancers in the first-in-human study conducted in China. **Methods:** CLARITY-PanTumor01 is an ongoing, global, phase 2 study (NCT06219941) evaluating Sone-Ve in gastric/GEJ cancers, PDAC, and BTC outside of China. Here we report data for pts with CLDN18.2+ advanced or metastatic gastric/GEJ cancers and ≤2 lines of prior systemic therapy (substudy 1) receiving Sone-Ve 2.2 mg/kg IV Q3W (pts randomized to 1.8 mg/kg are not reported). Primary endpoints were safety and objective response rate (ORR; 30 pts were selected to estimate ORR; lack of efficacy is concluded if ≤6 confirmed responses). Secondary endpoints included duration of response (DoR) and progression-free survival (PFS). Molecular responses (MRs) based on circulating tumor DNA (ctDNA) were evaluated. **Results:** As of Oct 31, 2025, 67 pts received Sone-Ve 2.2 mg/kg, including 30, 31, and 6 pts from the randomized (RC), paired biopsy (PBC), and Japanese safety (JSC) cohorts, respectively. All pts had adverse events (AEs; grade ≥3 in 34.3% overall, 36.7% of the RC, and 35.5% of the PBC). The most common grade ≥3 AEs were neutrophil count decreased (7.5%), anemia (7.5%), vomiting (6.0%), and nausea (6.0%). Dose reductions were most commonly due to gastrointestinal (GI) AEs and occurred in 40.3% of pts overall, 56.7% of the RC, and 19.4% of the PBC (adoption of a 4-drug antiemetic regimen improved GI tolerability in the PBC). The ORR was 28.4% (95% CI: 18.0–40.7). Median DoR has not yet been reached. Additional data are in the Table. Among evaluable pts, 58.6% (17/29) had sufficient baseline ctDNA levels to enable MR analysis; of these, 10 (58.8%) had at least a partial MR (>50% ctDNA reduction) within 2 cycles of Sone-Ve initiation. **Conclusions:** Sone-Ve 2.2 mg/kg demonstrated clinically meaningful efficacy and a manageable safety profile consistent with the first-in-human study. ctDNA MRs were observed in over half the evaluable pts. Clinical trial information: NCT06219941. Research Sponsor: AstraZeneca.

An open-label phase Ib/II study of trastuzumab deruxtecan combined with nivolumab and CAPOX in patients with HER2-low gastroesophageal adenocarcinoma (EPOC2203). First Author: Yu Aoki, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: Trastuzumab deruxtecan (T-DXd) is standard of care for previously treated patients with HER2-positive metastatic gastroesophageal adenocarcinoma (mGEA) with exploratory analyses of the DESTINY-Gastric01 trial suggested activity in HER2-low (IHC 1+/2+ ISH-negative) disease and preclinical synergy with anti-PD-1 therapy. **Methods:** EPOC2203 (jRCT2031230477) is a prospective, multicenter, phase Ib/II study evaluating first-line T-DXd combined with nivolumab and CAPOX in HER2-low mGEA. Patients received T-DXd (5.4 or 4.4 mg/kg, day1) in combination with nivolumab (360mg/body, day1) and CAPOX (capecitabine 750 mg/m² twice daily on days 1–14; oxaliplatin 70 mg/m² on day 1) every 3 weeks. The primary endpoints were DLT rate to determine RP2D in phase Ib and ORR in phase II. Assuming a threshold ORR of 58% and an expected ORR of 80%, 28 patients in the full analysis set (FAS) treated at the RP2D were planned (one-sided $\alpha = 0.10$; power = 80%). **Results:** A total of 30 patients were enrolled. The median age was 59 years; 83.3% had HER2 IHC 1+ disease, 63.3% had gastric primary, and 96.7% had PD-L1 CPS ≥1. Two DLTs, both febrile neutropenia, occurred at T-DXd 5.4 mg/kg, while none were observed at 4.4 mg/kg in phase Ib part, which was selected as the RP2D. Among patients in the FAS (n = 28), the investigator-assessed ORR was 89.3% (80% CI, 77.7–96.0; $P< 0.001$), exceeding the prespecified threshold. At median follow-up of 10.1 months, median PFS was 8.1 months (95% CI, 5.6–not estimable). The 6-month OS was 89.3% (95% CI, 70.4–96.4). Six patients underwent conversion surgery, including three with pathological complete response. Grade ≥3 treatment-emergent adverse events occurred in 46.4% of patients who were treated at the recommended dose (n = 28). The most common grade ≥3 adverse events were neutropenia (25.0%), anemia (14.3%), febrile neutropenia (3.6%), and diarrhea (3.6%). Interstitial lung disease was observed in 3 patients (10.7%), with no grade ≥3 events. No treatment-related deaths were observed. **Conclusions:** T-DXd (4.4 mg/kg) combined with nivolumab and CAPOX demonstrated encouraging antitumor activity with a manageable safety profile as first-line treatment for HER2-low mGEA, supporting further evaluation. Clinical trial information: jRCT2031230477. Research Sponsor: Daiichi Sankyo.

Application of unsupervised genetic clustering to identify biologically distinct cholangiocarcinoma subtypes with differential survival. First Author: Qianchen Zhang, Carle Illinois College of Medicine, Urbana, IL

Background: Cholangiocarcinoma (CCA) is a genetically heterogeneous malignancy for which current anatomic and histologic classifications inadequately predict survival. We hypothesized that unsupervised machine learning clustering of mutations and copy number alterations(CNA) could identify biologically distinct CCA subgroups with clinically meaningful differences in survival. **Methods:** Genomic and clinical data were obtained from the MSK cholangiocarcinoma dataset from cBioPortal. 790 patients with intrahepatic and extrahepatic CCA with available mutation and CNA data were included. Multiple unsupervised approaches were evaluated, including k-means, hierarchical clustering, non-negative matrix factorization, PCA–k-means, and UMAP–k-means. Model performance was assessed using silhouette scores, with UMAP–k-means (n=4 clusters) selected as the optimal method. Clusters were defined by dominant genetic alterations and compared for overall survival using Kaplan–Meier analysis with pairwise log-rank testing. Subgroup analyses included patients without curative-intent surgery and a young-onset cohort. **Results:** UMAP–k-means delineated four distinct genomic clusters ordered by progressively worse median survival. Cluster 1, defined by *ARID1A* or *BAP1* mutations, demonstrated the most favorable survival outcomes. Cluster 2 consisted of tumors wild type for recurrent driver alterations. Cluster 3 was characterized by *TP53*, *KRAS*, or *IDH1* mutations. Cluster 4, defined by *CDKN2A* double deletion or *ERBB2* amplification, exhibited the poorest median survival. Overall survival differed significantly across clusters, with all pairwise Kaplan–Meier comparisons reaching statistical significance except between clusters 1 and 2. These survival differences remained significant in patients who did not undergo curative-intent surgery. Notably, cluster 4 remained associated with significantly worse survival within the young-onset cohort. **Conclusions:** Unsupervised genomic clustering using UMAP–k-means identified biologically distinct subtypes of cholangiocarcinoma, with clinically significant survival differences that persist across surgical and age-based subgroups. These findings support future genomic subtyping as a prognostic framework and a rationale for biology-driven clinical trial stratification in cholangiocarcinoma. Research Sponsor: None.

Unsupervised genetic clustering identifies biologically distinct cholangiocarcinoma subtypes with differential survival.

Cluster	Primary Genetic alterations	N patients	Median OS	log-rank test P-value vs cluster 2	log-rank test P-value vs cluster 3	log-rank test P-value vs cluster 4
1	ARID1A or BAP1 mutant	120	28.0	0.308	<0.001	<0.001
2	Wild types	224	26.7	-	0.003	<0.001
3	TP53, KRAS or IDH1 mutant	319	22.0		-	0.002
4	CDKN2A deletion or ERBB2 amplification	127	16.9			-

Disitamab vedotin (DV) plus toripalimab (Tor) and chemotherapy (Chemo)/ trastuzumab (Tra) for first-line (1L) HER2-expressing locally advanced or metastatic (la/m) gastric cancer (GC): Updated results from the RC48-C027 trial. First Author: Zhi Peng, Department of GI Oncology, Peking University Cancer Hospital & Institute, Beijing, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

4027 **Poster Session**

A phase 2 clinical study of nimotuzumab plus S-1 and concurrent radiotherapy in 75 years and older patients with esophageal squamous cell carcinoma. First Author: Xiaojie Xia, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Concurrent chemoradiotherapy is the standard treatment method for inoperable and locally advanced esophageal cancer. Nevertheless, due to decreased physical function and the presence of multiple complications, older patients often have reduced tolerance to radiotherapy and chemotherapy. **Methods:** We conducted this prospective, single-center, phase II study to evaluate the efficacy and safety of nimotuzumab (an epidermal growth factor receptor antibody) plus concurrent radiotherapy and S-1 in 75 years and older patients with stage II-IVB esophageal squamous cell carcinoma (ESCC). The primary endpoint was progression-free survival (PFS). The secondary endpoints were overall survival (OS), objective response rate (ORR), disease control rate (DCR), safety, nutritional indicators, and quality of life (QOL). Most nutritional indicators remained stable after treatment. **Results:** As of June 2024, a total of 56 patients were enrolled in this study. The median follow-up was 24.1 months (95% CI: 8.8, 34.1). 11 patients had complete response, 39 patients had partial response, 5 patients had stable disease, and 1 patient had progressive disease. The ORR was 89.2%, and the DCR was 98.1%. The 1- and 3-year PFS rates were 67.8% (95% CI: 55.5%, 80.1%) and 35.8% (95% CI: 17.6%, 54.0%), with the median PFS was 25.3 months (95% CI: 16.5, 34.1). The 1- and 3-year OS rates were 79.6% (95% CI: 68.8%, 90.4%) and 40.1% (95% CI: 21.1%, 59.1%), with the median OS was 28.2 months (95% CI: 24.1, 32.3). Most adverse events were grade 1-2 (85.7%). Among survivors, 45.5% patients reported high satisfaction with their QOL, and 84.8% patients did not experience weight loss. **Conclusions:** Our treatment combination of nimotuzumab plus S-1 and concurrent radiotherapy indicated favorable efficacy and safety profile. This might be an underlying treatment choice for older patients with ESCC. Clinical trial information: NCT06048913. Research Sponsor: None.

Preclinical efficacy of the anti-EBV agent brincidofovir (BCV) in EBV-associated gastric carcinoma (EBVaGC). First Author: Tetsu Kamitani, SymBio Pharmaceuticals, Tokyo, Japan

Background: Immune checkpoint inhibitor (ICI) plus chemotherapy is an approved therapy for EBVaGC whose tumors express PD-L1 (CPS $\geq$1). However, some patients are resistant to ICI or exhibit myelosuppression, making them unable to tolerate chemotherapy. BCV, an antiviral drug with no myelotoxicity, is effective against EBV (EC50: 30 nM), and has demonstrated anti-tumor activity against head and neck cancer and EBV-associated lymphoma. Recently, we found that SNU-719, an EBVaGC cell line, is sensitive to BCV *in vitro* (IC50: 1.95 μM). To seek conventional chemo-free regimens for EBVaGC, we have studied the preclinical efficacy of BCV monotherapy and combination therapy with ICI against EBVaGC. **Methods:** BCV was tested for its ability to induce dsDNA breaks in SNU-719 cells by γ-H2A.X immunostaining. To assess synergy of BCV with ICI, we analyzed BCV-induced immunogenic cell death (ICD) in SNU-719 cells using calreticulin and HMGB-1 assays. Additionally, we assessed BCV-induced expression of PD-L1 using qPCR and FACS. Since BCV induced both ICD and PD-L1 expression *in vitro*, we then evaluated the *in vivo* anti-tumor activity of BCV with or without ICI in humanized NOG mice bearing SNU-719 xenografts. Specifically, mice received intraperitoneal administration of vehicle, BCV, pembrolizumab (Pembro), or Pembro+BCV. Subcutaneous tumor growth was monitored for each group. After euthanasia, the SNU-719 xenografts were also used to measure the mRNA expression levels of EBV genes including *EBNA1*. **Results:** BCV induced both dsDNA breaks and ICD in SNU-719 cells, similar to the positive control bleomycin. It also induced PD-L1 mRNA and protein expression. Subsequent *in vivo* studies showed that, while BCV or Pembro monotherapy showed partial efficacy, the combination therapy of BCV and Pembro was effective in all mice. Notably, treatment with BCV significantly reduced the expression levels of *EBNA1* mRNA ($p < 0.05$) in the tumor tissue of SNU-719 xenografts. **Conclusions:** EBV is an oncovirus and its gene product EBNA1 is an oncoprotein for EBVaGC. This study showed a significant reduction of *EBNA1* mRNA expression by BCV. Therefore, in addition to its own anti-tumor effects, BCV may contribute significantly to the suppression of EBVaGC tumorigenesis via its anti-EBV activity. From a clinical perspective, BCV was effective against EBVaGC xenografts when combined with ICI. This less toxic regimen may be beneficial for EBVaGC patients, especially those with myelosuppression. Research Sponsor: SymBio Pharmaceuticals Limited.

Early treatment failure despite first-line immunotherapy in real-world MSI-H/dMMR gastroesophageal cancer. First Author: Shannon L. Rhodes, Amgen, Inc., Thousand Oaks, CA

Background: Clinical trials of first-line (1L) immunotherapy (IO) in gastroesophageal cancer (GEC) demonstrate greater benefit in patients with microsatellite instability–high or mismatch repair–deficient (MSI-H/dMMR) tumors compared with the overall trial population. However, the benefit is not universal, and outcomes remain suboptimal for a subset of patients. Real-world (RW) evidence describing outcomes with 1L IO in MSI-H/dMMR GEC is limited. This study characterized treatment patterns and outcomes among RW MSI-H/dMMR GEC patients treated with 1L IO to better define residual unmet need. **Methods:** Using the Flatiron Health electronic health record-derived deidentified database, adults (≥18 years) diagnosed with locally advanced unresectable, metastatic, or recurrent gastric (GC), gastroesophageal junction (GEJ), or esophageal cancer (EC) between 17 Apr 2021 and 31 Dec 2024 were identified. Patients were required to have documented MSI-H or dMMR status and no trastuzumab exposure. Data were available through 08 Sep 2025. Time to next treatment or death served as a RW proxy for progression. **Results:** Among 3,047 eligible patients, MSI-H/dMMR prevalence varied by disease site and stage, ranging from 5.8% in metastatic GC to 17.6% in locally advanced GC; from 2.4% to 10.4% in GEJ disease; and from 3.4% to 4.4% in EC. A total of 199 MSI-H/dMMR GEC patients were identified (median age 75 years [IQR 66–82]; 36% female; 37% metastatic at diagnosis; 95% adenocarcinoma). Of the 155 MSI-H/dMMR patients who received 1L therapy, 32% received IO alone, 31% IO plus chemotherapy, and 37% chemotherapy alone. Among patients treated with 1L IO ± chemotherapy, 37% initiated 2L therapy or died within 6 months, increasing to 47% and 54% by 9 and 12 months, respectively. Baseline characteristics were largely similar between patients with and without progression within the first 12 months (Table). **Conclusions:** In this real-world cohort of MSI-H/dMMR GEC patients, a substantial proportion experienced early treatment failure despite 1L IO. More than one-third initiated second line therapy or died within 6 months, and over half progressed or died within 1 year. These findings underscore heterogeneity in benefit from 1L IO and highlight an ongoing need for improved risk stratification and alternative precision-based treatment approaches. Research Sponsor: None.

Characteristics of MSI-H/dMMR GEC patients by progression status at 12 months post start of 1L IO therapy.

		Progressors N=35	Non-progressors** N=30
Age, Median [IQR]		72 [66, 83]	73 [64, 80]
Female, %		34.3	40.0
Location, %	GC	62.9	63.3
	GEJ	8.6	13.3
	EC	28.6	23.3
Status*, %	Metastatic	48.6	46.7
	Non-metastatic	45.8	50.0
ECOG at 1L*, %	0/1	25.7	26.7
	2+	57.1	50.0

*Some patients are missing disease status and/or ECOG.
**Patients included in non-progressors were required to have activity in the data at least 12 months after 1L IO initiation.

Tislelizumab (Tisle) combined with POFI (irinotecan, paclitaxel, oxaliplatin, and 5-FU/levoleucovorin) as first-line treatment for advanced gastric/gastroesophageal junction adenocarcinoma (AGC): Update from a single-arm, open-label phase I/II trial (SYLT-023). First Author: Jiajing Chen, Department of Gastrointestinal Medical Oncology, Fujian Cancer Hospital, Fuzhou, China

Background: Tisle is an anti-PD-1 antibody. The combination of Tisle + XELOX/FP is a first-line treatment of AGC in China. Both irinotecan and paclitaxel have also shown antitumor activity in AGC. This Phase I/II study evaluated the efficacy and safety of Tisle + POFI in this population. **Methods:** This single-center, single-arm phase I/II study enrolled treatment-naïve patients with pMMR/MSS AGC, aged 18-75, who have at least one measurable lesion according to RECIST 1.1 and an ECOG PS of 0-1. Eligible participants received POFI (irinotecan/paclitaxel (mg/m2): 135/45 (dl #1), 150/45 (dl #2), 135/67.5 (dl #3), and 135/90 (dl #4), oxaliplatin 85 mg/m^2, levoleucovorin 200 mg/m^2, and 5-FU 2400 mg/m^2 for 46 hours every 2 weeks) in combination with Tisle 200mg every 2 weeks. The primary endpoint was the objective response rate (ORR) per RECIST 1.1. **Results:** As of Dec. 23, 2025, 47 patients were enrolled (median age: 58 years, range: 31–72; 26%(12/47) ECOG PS 1; 74% poorly differentiated; 68%(32/47) with ≥2 metastatic sites; 34% with programmed death-ligand 1 combined positive score [PD-L1 CPS] ≥1). The confirmed ORR was 76.6% (36/47), and the disease control rate was 95.7%. Median progression-free survival (PFS) was 11.1 months (95% CI: 8.8, 13.4) (versus 6.9 months (5.7-7.2) for ITT population for RATIONALE 305, ESMO 2023). Median duration of response was 9.7 months (95% CI: 6.7, 12.2). Median overall survival was 16.0 months (95% CI: 12.4, 23.0). All patients experienced treatment-emergent adverse events. The most common grade 3/4 adverse events included neutropenia (53.2%), leukopenia (27.7%), and anemia (21.3%). No new safety signals were identified. **Conclusions:** Tisle + POFI showed promising efficacy and a manageable safety profile as first-line treatment for HER2-negative, pMMR/MSS AGC, warranting further investigation. Clinical trial information: NCT05319639. Research Sponsor: None.

CLDN18.2–targeting antibody-drug conjugate BA1301 in advanced solid tumors: Results from a phase I clinical trial. First Author: Dan Su, Gastroenterology Department, The Affiliated Cancer Hospital of Harbin Medical University, Harbin, China

Background: Aberrant expression of claudin18.2 (CLDN18.2) has frequently been observed in various solid tumors, making it a promising therapeutic target for those aggressive cancers. BA1301 is an ADC consisting of a fully humanized anti-CLDN18.2 monoclonal antibody conjugated to monomethyl auristatin E, a potent cytotoxic agent via site-specific glycol conjugation and a cleavable linker with a drug-to-antibody ratio of 4. Here we reported the results from a phase 1 dose escalation and dose expansion study of BA1301. **Methods:** Eligible pts failed or intolerant to standard therapy were enrolled. BA1301 was intravenously administered with accelerated titration (0.1/0.4 mg/kg Q3W) and traditional 3+3 design (1.2/2.0/2.5/3.0mg/kg Q3W). Dose expansion was evaluated at 1.6/2.0/2.5mg/kg Q3W. CLDN18.2 was test by immunohistochemistry [IHC] Claudin18.2 (EPR19202-244) Assay developed by Medx. Moderate to high expression of CLDN18.2 defined as IHC membrane staining intensity ≥2 in ≥40% of tumor cells. Endpoints were safety and efficacy per RECIST v1.1. **Results:** As of Dec 22, 2025, a total of 91 patients with advanced cancers (gastric cancer [59, 64.8%], biliary tract cancer [14, 15.4%], pancreatic cancer [11, 12.1%], gynecologic cancers [3, 3.3%] and other 4 tumor types) were enrolled, 49 (53.8%) patients had received ≥2 systemic therapies (median 2, range 1-7). In dose escalation (n = 24), No DLTs were observed.80 (87.9%) patients had at least one treatment-related adverse events (TRAEs), and 33 (36.3%) had grade 3 or 4 TRAEs. The most common TRAEs were corneal disorder (51, 56.0%) and anemia (30, 33.0%). 3(3.3%) pts discontinued treatment due to TRAEs, and no treatment related death reported. Among patients with CLDN18.2 moderate to high expression (N=76), 69 at the ≥1.6 mg/kg dose level had at least one post-baseline tumor assessment. Key efficacy outcomes are presented (Table). **Conclusions:** BA1301 was well-tolerated with a manageable safety profile and demonstrated promising anti-tumor activity in patients with CLDN18.2 moderate to high expression. The findings support further development of BA1301 as a new therapeutic approach to treat CLDN18.2-positive solid tumors. The trial (NCT06927349) is ongoing in China. Clinical trial information: NCT06927349. Research Sponsor: None.

Cancer Type	ORR n (%) [95%CI]	DCR n (%) [95%CI]

Prognostic impact of AXL expression in upper gastrointestinal cancer in MONSTAR-SCREEN-2: An international collaborative study between United States and Japan. First Author: Kyosuke Seguchi, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: AXL, a receptor tyrosine kinase of the TAM family, promotes epithelial-mesenchymal transition (EMT) and tumor progression. Elevated AXL expression is reported as poor prognostic factor with immunosuppressive features in colorectal cancer (Karam Ashouri, et al. J Immunother Cancer. 2025). We investigated the prognostic impact of AXL expression and its associated molecular and tumor microenvironment (TME) features in upper gastrointestinal (GI) cancers. **Methods:** Treatment-naïve patients with gastric cancer (GC) and esophageal cancer (EC) enrolled in MONSTAR-SCREEN-2 with available RNA-seq data (Caris MI TumorSeek) were analyzed. AXL expression was dichotomized by median into high and low groups within each cancer type. Molecular alteration, including somatic mutations and copy number alterations, and expression of receptor tyrosine kinases, including FGFRs, VEGFRs, and EGFR were compared between groups. Overall survival (OS) was evaluated using Kaplan-Meier analysis and Cox proportional hazards models. Tumor microenvironment (TME) cell infiltration, assessed using xCell deconvolution and gene set enrichment analysis (GSEA) performed using Hallmark gene sets, was compared between AXL-high and AXL-low groups. **Results:** A total of 320 patients were analyzed (GC: n = 270; EC: n = 50). In GC, AXL-high patients were older than AXL-low patients (median 71 vs 66 years, p = 0.012), while no other baseline characteristics, including sex, histology, primary site, metastatic sites, microsatellite instability-high, and tumor mutation burden-high status, differed between groups. *ARID1A* mutations were enriched in AXL-high GC ($p < 0.05$), while *CCNE1* amplification was associated with AXL-low ($p < 0.05$). Across both cancer types, AXL-high tumors exhibited significantly higher expression of FGFR1, VEGFR1-3, and MET ($p < 0.01$). In GC, AXL-high was associated with significantly shorter OS compared to AXL-low (median 12.9 vs 16.6 months; HR 1.44, 95%CI 1.03-2.02; p = 0.034). Similarly in EC, AXL-high showed worse OS compared to AXL-low (median 10.4 vs not reached; HR 2.46, 95%CI 1.08-5.62; p = 0.027). TME analysis revealed increased stromal scores, endothelial cells, M1/M2 macrophages, and regulatory T cells, along with higher expression of immune checkpoint molecules, including PD-L2 and CTLA4, in AXL-high tumors. GSEA showed enrichment of EMT, IFN-γ response, and PI3K/AKT/mTOR pathways in AXL-high GC. **Conclusions:** AXL overexpression is a prognostic biomarker in upper GI cancers, and is associated with worse survival and a distinct molecular and immune landscape characterized by EMT activation and immune-suppressive TME. These findings support AXL as a potential therapeutic target and warrant further investigation of AXL-targeted therapy in upper GI cancers. Research Sponsor: None.

CDH17 expression and tumor microenvironment composition in gastric cancer. First Author: Ammanuel Taye, Yale School of Medicine, New Haven, CT

Background: Cadherin 17 (CDH17), commonly referred to as liver-intestine cadherin, is a calcium-dependent cell adhesion molecule, is overexpressed across multiple gastrointestinal epithelial malignancies and is implicated in tumorigenesis and aggressive tumor phenotypes through diverse signaling pathways. Preclinical studies have demonstrated the therapeutic potential of anti-CDH17 approaches across multiple therapeutic modalities. However, the relationship between CDH17 and cellular characteristics within the gastric cancer tumor microenvironment (TME) is yet to be sufficiently characterized. **Methods:** To systematically investigate the association between CDH17 expression and TME composition in gastric cancer, we conducted a comprehensive multi-cohort analysis of clinically annotated gastric cancer samples with RNA sequencing data. Within each cohort, CDH17 expression levels were quantified and dichotomized into high and low expression groups based on cohort-specific median transcripts per million (TPM) values. We applied the xCell immune deconvolution algorithm to estimate the relative immune and stromal cell populations enrichment across all samples. **Results:** In total, we studied 1,811 samples within ten datasets. CDH17 high-expressing gastric cancers demonstrated a distinctive TME signature characterized by selective cellular depletion rather than generalized immune suppression. Natural killer (NK) cell enrichment was identified in three cohorts; however, this pattern lacked pan-cohort consistency. Notably, CDH17 high expression was associated with significant depletion in multiple critical effector populations, including CD8+ cytotoxic T lymphocytes (CD8+ T-cells: 6/10 cohorts $p < 0.05$), myeloid dendritic cells and cancer-associated fibroblasts (8/10 cohorts, $p < 0.05$), and hematopoietic stem cells (5/10 cohorts, $p < 0.05$). In contrast, other immune and stromal cell populations demonstrated heterogeneous patterns of association with CDH17 expression, with no clear or uniform enrichment or depletion across cohorts. **Conclusions:** CDH17 high-expressing gastric cancers harbor an immunologically "cold" tumor microenvironment characterized by selective depletion of critical effector immune and stromal cell populations. Research Sponsor: None.

Quality-adjusted survival comparison for tislelizumab (TIS) + chemotherapy (CT) versus placebo (PBO) + CT as first-line (1L) treatment in gastric/gastroesophageal junction adenocarcinoma (GC/GEJC) patients with peritoneal metastasis (PM): Long-term follow-up from RATIONALE-305. First Author: Rutika Mehta, NewYork-Presbyterian Hospital/ Weill Cornell Medicine, New York, NY

Background: There is an unmet need for better treatment among patients (pts) with PM. A post hoc analysis of the phase 3 RATIONALE-305 (NCT03777657) trial showed that TIS + CT as 1L treatment for GC/GEJC pts with PM improved survival compared to PBO + CT (Qiu et al, 2025). The current study evaluated whether this survival benefit translated into quality of life (QoL) adjusted survival gains. **Methods:** This post hoc analysis used long-term follow-up data from the RATIONALE-305 trial (minimum follow-up 3 years; data cutoff February 28, 2024). The analysis focused on the intent-to-treat (ITT) population and subgroups defined by programmed death ligand-1 (PD-L1) ≥1% as well as ≥5% by Tumor Area Positivity (TAP) score. The well-established Quality-adjusted Time Without Symptoms or Toxicity (Q-TWiST) methodology was used. QoL adjusted survival was calculated as the average time spent in three distinct health states during the trial follow-up: survival time with grade 3/4 toxicity, survival without progression/toxicity, and survival post progression, each weighted by QoL utility parameters specific to that state. A sensitivity analysis (SA) using trial-derived, treatment-specific EQ-5D utility values was also conducted. QoL adjusted relative survival gains ≥15% were considered "clearly clinically important," in line with commonly accepted Q-TWiST benchmarks (DOI 10.1007/s11136-005-1579-7). **Results:** At the maximum follow-up of 57 months in all randomized pts in RATIONALE-305, TIS + CT (n=501) pts experienced greater mean QoL adjusted survival than PBO + CT (n=496) (16.3 vs 13.1 months). Among pts with PM, TIS + CT (n=220) showed higher mean QoL adjusted overall survival than PBO + CT (n=214) (13.4 vs 10.8 months; 17.7% relative Q-TWiST gain) that was clearly clinically important. QoL adjusted survival benefit was also clearly clinically important in TIS + CT pts with PM with PD-L1 TAP score ≥1% (16.8% gain) and PD-L1 score ≥5% (33.0% gain) compared with PBO + CT. SA results further favored TIS + CT (Table). **Conclusions:** Treatment with TIS + CT resulted in clinically meaningful improvement in long-term quality-adjusted survival for GC/GEJC pts with PM versus those receiving CT alone. Clinical trial information: NCT03777657. Research Sponsor: BeOne Medicines, Ltd.

TIS + CT vs PBO + CT treatment difference.

	Mean Q-TWiST, months (95% CI)	Relative Q-TWiST Gain
Pts with PM[a]		
ITT pts (n=434)	2.6 (0.1 to 5.0), *P*=0.04	17.7%
PD-L1 TAP ≥1% (n=386)	2.5 (0.1 to 5.1), *P*<0.05	16.8%
PD-L1 TAP ≥5% (n=217)	4.7 (1.1 to 8.6), *P*=0.02	33.0%
Pts with PM (SA using EQ-5D scores)[b]		
ITT pts (n=434)	3.1 (0.8 to 5.5), *P*<0.01	21.3%
PD-L1 TAP ≥1% (n=386)	3.1 (0.5 to 5.6), *P*=0.02	20.8%
PD-L1 TAP ≥5% (n=217)	4.8 (1.3 to 8.2), *P*<0.01	33.9%

Real-world adoption and sequencing of CLDN18.2, PD-L1, and HER2 testing in advanced gastric and gastroesophageal junction adenocarcinoma. First Author: Yifei Zhang, Yale University School of Medicine, New Haven, CT

Background: The FDA approval of zolbetuximab for CLDN18.2-positive advanced gastric and gastroesophageal junction adenocarcinoma (GEA) in Oct 2024, based on the SPOTLIGHT and GLOW trials, represents an important advance in biomarker-driven therapy. We aimed to describe real-world adoption of CLDN18.2 testing in the US, and CLDN18.2 co-expression with other clinically relevant biomarkers. **Methods:** Using the US-based, electronic health record-derived deidentified Flatiron Health Research Database, we evaluated biomarker testing patterns among patients diagnosed after 2016 across three periods: pre-SPOTLIGHT publication (2016–2022), post-SPOTLIGHT/pre-FDA approval (Jan 2023–Sep 2024), and post-FDA approval (Oct 2024 onward). We assessed CLDN18.2 testing uptake and co-expression with PD-L1 and HER2. **Results:** In total, our study included 11,099 patients (7,515 pre-SPOTLIGHT, 2,364 pre-FDA, 1,220 post-FDA). Compared to HER2 testing, 1.1% had CLDN18.2 testing pre-SPOTLIGHT, 21.3% pre-FDA and 39.5% post-FDA. The prevalence of biomarker positivity was as follows: HER2 20.1% (2,617/13,033), PD-L1 25.6% (1,913/7,487), CLDN18.2 42.6% (473/1,109). Among patients tested for all three biomarkers with available result dates, 69.9% underwent upfront comprehensive testing (HER2, PD-L1, CLDN18.2 within one week), while 30.1% had sequential testing, with a median interval of 91 days between tests. Among 1,034 patients tested for all three biomarkers, 13.9% were dual PD-L1/CLDN18.2 positive, and 4.4% were triple-positive. **Conclusions:** In this real-world analysis, CLDN18.2 testing uptake increased following SPOTLIGHT but remained incomplete, and nearly one-third underwent sequential rather than upfront comprehensive biomarker testing, resulting in clinically meaningful delays. These findings highlight the need for improved education and implementation of upfront, comprehensive biomarker testing strategies to optimize treatment sequencing and preserve therapeutic options for patients with GEA. Phase I/II trial of anti-CLDN18.2/PD-L1 recombinant humanized bispecific antibody Q-1802 plus XELOX in treatment-naive CLDN18.2-positive advanced GC/GEJ. First Author: Jifang Gong, Department of Gastrointestinal Oncology, Peking University Cancer Hospital & Institute, Beijing, China

Background: First-line therapy for HER2-negative advanced GC/GEJ remains a huge unmet clinical need. Claudin 18.2 (CLDN18.2), a tight junction protein, is specifically expressed in normal gastric mucosa but aberrantly overexpressed in various cancers, making it a high-value therapeutic target. Q-1802 is a first-in-class humanized bispecific antibody targeting both CLDN18.2 and PD-L1. Q-1802 can bind CLDN18.2 on tumor cells and kill them through Fc mediating antibody-dependent cellular cytotoxicity (ADCC) and phagocytosis (ADCP). Meanwhile, it can activate immune system to eliminate tumor cells by blocking PD-1/PD-L1 binding. **Methods:** Qure-1802-201 was a multicenter, open-label, nonrandomized phase I/II trial. Eligible pts: CLDN18.2-positive (≥40% tumor cells with 2+/3+ membranous staining), HER2-negative, treatment-naïve, histologically confirmed unresectable locally advanced/metastatic GC/GEJ. Pts received Q-1802 (10 mg/kg or 20 mg/kg Q2W) plus standard XELOX (oxaliplatin IV d1; capecitabine PO d1-14 Q3W). Primary endpoints: DLT/MTD (Phase I) and ORR per RECIST v1.1 (Phase II). Secondary endpoints: efficacy, safety, pharmacokinetics, pharmacodynamics, immunogenicity. **Results:** As of Dec 11, 2025, 62 pts were enrolled (45 in 10 mg/kg, 17 in 20 mg/kg). No DLT observed; MTD not reached. All pts had TEAEs and Q-1802-related TEAEs; the latter mainly included nausea (75.8%), AST increase (61.3%), nausea (59.7%), ALT increase (51.6%), fatigue (50.0%). Incidences of ≥3 Grade TEAEs and Q-1802-related ≥3 Grade TEAEs: 74.2% and 43.5%, respectively. Most common Q-1802-related ≥3 Grade TEAE: thrombocytopenia (8.1%), followed by neutropenia (6.5%), anemia, WBC decrease, hypokalemia (4.8% each). Rate of Q-1802 permanent discontinuation due to TEAEs: 6.5%; no treatment-related death. ORR and median progression-free survival (mPFS) in 60 efficacy-evaluable pts were 70.0% (42/60; 95% CI: 56.8%–81.2%) and 11.3 months (95% CI: 8.0–16.8). A correlated trend was observed between efficacy and CLDN18.2 expression. In the 10 mg/kg cohort, ORR and mPFS were 73.0% (27/37; 95% CI: 55.9%–86.2%) and 11.3 months (95% CI: 7.1–16.8) in pts with CLDN18.2 high expression (2+/3+≥70%, N = 37), which were improved to 81.8% (9/11; 95% CI: 48.2%–97.7%) and 12.2 months (95% CI: 2.7–NE) when CLDN18.2 high expression companied with PD-L1 CPS≥5 (N = 11). DCR was nearly complete (non-response in 1 of 60 pts). ORR in the 20 mg/kg cohort (70.6%, 12/17; 95% CI: 44.0%–89.7%) was similar to 10 mg/kg (69.8%, 30/43; 95% CI: 53.9%–82.8%.). Overall survival (OS) in all pts and PFS in the 20 mg/kg cohort are under follow-up. **Conclusions:** Q-1802 plus XELOX has manageable safety and promising antitumor activity as first-line therapy for CLDN18.2-positive/HER2-negative advanced GC/GEJ, supporting a phase III trial (Q-1802 10 mg/kg as recommended dose). Clinical trial information: NCT05964543. Research Sponsor: None.

A phase 1 study of SHR-3821, an ADCC-enhanced CLDN18.2/4-1BB bispecific antibody, in patients with advanced solid tumors. First Author: Hongfeng Gou, Gastric Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: CLDN18.2 is a highly selective tumor-associated antigen overexpressed in gastrointestinal malignancies, and has emerged as a promising therapeutic target. 4-1BB is a co-stimulatory receptor expressed on activated immune cells; its activation enhances antitumor immunity. SHR-3821 is an ADCC-enhanced bispecific antibody that specifically targets CLDN18.2 and activates 4-1BB in a CLDN18.2-dependent manner, enabling tumor-specific killing while minimizing systemic toxicity. This phase 1 study aims to evaluate the safety, tolerability, pharmacokinetics, and preliminary efficacy of SHR-3821 in patients with CLDN18.2-positive advanced solid tumors. **Methods:** Eligible patients had CLDN18.2-positive advanced solid tumors that had progressed on or lacked standard therapies. Patients received SHR-3821 via intravenous infusion every 3 weeks at prespecified dose levels: 0.1, 1, 3, 10, 15, 20 and 30 mg/kg during dose escalation (using a Bayesian optimal interval design), followed by dose expansion and efficacy expansion at 15 and 20 mg/kg. Primary endpoints included safety, maximum tolerated dose, and recommended phase 2 dose. **Results:** As of November 30, 2025, 40 patients with CLDN18.2-positive advanced solid tumors (23 gastric cancer [GC], 17 pancreatic cancer [PC]) were treated with SHR-3821 at doses ranging from 0.1 to 20 mg/kg. No dose-limiting toxicities occurred, and the maximum tolerated dose was not reached across the evaluated dose range. Grade ≥3 treatment-related adverse events (TRAEs) occurred in 15 patients (37.5%), most commonly decreased neutrophil count (20.0%), decreased lymphocyte count (7.5%), and vomiting (5.0%). No TRAEs led to death; one (2.5%) patients discontinued treatment due to TRAEs. Preliminary pharmacokinetic analyses demonstrated dose-proportional increases in systemic exposure following a single 1–20 mg/kg administration, with terminal elimination half-lives ranging from 4.2 to 7.0 days. ORR in GC were 22.2% at 15 mg/kg and 37.5% at 20 mg/kg (Table). **Conclusions:** SHR-3821 showed tolerable safety and promising antitumor activity in patients with CLDN18.2-positive GC and PC. These data support further clinical development of SHR-3821. Clinical trial information: NCT06618651. Research Sponsor: Jiangsu Hengrui Pharmaceuticals.

Randomized phase II trial of trifluridine/tipiracil (FTD/TPI) plus ramucirumab (RAM) versus FTD/TPI for previously treated patients with advanced gastric or gastroesophageal junction adenocarcinoma: Final analysis of RETRIEVE study (WJOG 15822G). First Author: Hirokazu Shoji, Department of Gastrointestinal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: Promising activity of trifluridine/tipiracil (FTD/TPI) plus ramucirumab (RAM) has been reported in single-arm phase II trials as third- or later-line treatment for advanced gastric cancer (GC) and gastroesophageal junction (GEJ) adenocarcinoma (Lancet Gastroenterol Hepatol. 2021; 6: 209-217). We previously reported the primary analysis of the RETRIEVE study at ASCO-GI 2026, which demonstrated no significant difference in progression-free survival (PFS; median 2.69 vs 2.07 months) between FTD/TPI plus RAM and FTD/TPI alone. Here, we present the final analysis, including overall survival (OS) as a key secondary endpoint, along with updated results of other endpoints. **Methods:** RETRIEVE study is a multicenter, prospective, open-label, randomized phase II trial comparing FTD/TPI plus RAM versus FTD/TPI alone in patients with unresectable or recurrent GC or GEJ adenocarcinoma who were refractory or intolerant to fluoropyrimidine, taxane, or irinotecan, and refractory to RAM. Treatment is repeated every 4 weeks until disease progression or unacceptable toxicity. Key eligibility criteria include age of ≥20 years; ECOG performance status of 0 or 1, and at least a measurable lesion per RECIST 1.1. **Results:** Between January 2023 and June 2024, 111 patients were randomly assigned to receive FTD/TPI plus RAM (n = 56) or FTD/TPI alone (n = 55). At a median follow-up of 18.4 months, median OS was 6.08 months in the combination arm and 7.36 months in the monotherapy arm (hazard ratio [HR], 1.233; 95% CI, 0.817–1.862; P = 0.318). The proportion of patients who received subsequent treatment was 64.3% in the combination arm and 56.4% in the monotherapy arm. In the updated analysis, median PFS was 2.69 months in the combination arm and 2.07 months in the monotherapy arm (HR, 1.010; 80% CI, 0.781–1.307; P = 0.959). Objective response rate (ORR; 5.4% vs 9.1%, P = 0.489) and disease control rate (DCR; 50.0% vs 47.3%, P = 0.850) were consistent with the primary analysis. No novel adverse events were identified from the primary analysis. Any grade of n (49.1% vs 25.5%) and diarrhea (29.1% vs 14.5%) were more frequently observed in the combination arm than in the monotherapy arm. **Conclusions:** The final analysis demonstrated that FTD/TPI plus RAM did not provide a significant OS benefit compared with FTD/TPI alone in third- or later-line treatment for advanced GC and GEJ adenocarcinoma. Updated results of PFS, tumor response, and safety profile were consistent with the primary analysis. Clinical trial information: jRCTs041220120. Research Sponsor: Taiho Pharmaceutical Co., Ltd.

Evaluation of homologous recombination deficiency (HRD) in gastric cancer: Real-world prevalence and outcomes with first-line (1L) platinum-based therapy. First Author: Dani Ran Castillo, Department of Medical Oncology, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: Metastatic gastric and gastroesophageal junction cancers (GC/GEJ) have poor outcomes with limited predictive biomarkers to guide first-line (1L) therapy. HRD predicts sensitivity to platinum chemotherapy and PARP inhibition in several malignancies, but its clinical relevance is not well defined in GC/GEJ. We evaluated the association between HRD alterations, genomic context, and clinical outcomes following 1L platinum-based therapy (PBT) in metastatic GC/GEJ. **Methods:** We queried the de-identified Tempus multimodal database using the Tempus Lens Platform to analyze a cohort of patients with advanced GC/GEJ. All patients had DNA (xT, 648 gene DNA-seq panel) and/or RNA sequencing (xR, whole transcriptome RNA-seq). Patients were classified as HRD-altered (HRD-alt) if they harbored pathogenic or likely pathogenic germline or somatic alterations in at least one of 23 predefined HRD-associated genes; all others were classified as HRD wild-type (HRD-wt). Tumor mutational burden (TMB-H, ≥ 10 mut/Mb) and microsatellite instability (MSI) were assessed. Real-world (rw) overall survival (rwOS) was estimated using Kaplan–Meier methods. Hazard ratios (HRs) from Cox-proportional hazards models were adjusted for relevant clinical and molecular covariates at a significance level of $p < 0.05$. **Results:** Among 1,066 eligible patients, 257 (24%) were HRD-alt and 809 (76%) were HRD-wt. HRD-alt tumors were associated with TMB-H (21% vs 5.9%, $p< 0.001$) and MSI-high status (12% vs 1.2%, $p< 0.001$). Median OS was longer in HRD-alt compared with HRD-wt patients (15 vs 12 months, HR: 0.79, p = 0.033). Notably, HRD-alt tumors were strongly enriched for ERBB2 alterations compared to HRD-wt tumors (30% vs 8.8%, $p< 0.001$), predominantly driven by amplification (86%). Further stratification by HRD and ERBB2 status showed reduced HRs for rwOS in HRD-alt only (HR 0.78; 95%, p = 0.034), dual ERBB2/HRD-alt tumors (HR 0.63; 95% CI, 0.45–0.88, p = 0.006), and ERBB2-alt only (HR 0.52; 95% CI, 0.36–0.76, p < 0.001) compared to the wt/wt group. ERBB2-alt tumors demonstrated distinct co-mutation patterns enriched for cell-cycle and proliferative genes (*CCNE1, TOP2A)*, whereas *ERBB2*–wt tumors more frequently harbored *KRAS*, *ARID1A*, and *CDH1* alterations. **Conclusions:** In this large rw-cohort of metastatic GC/GEJ, HRD alterations identified a biologically distinct subgroup with improved OS and greater durability on 1L PBT. HRD status was associated with *ERBB2* amplification, and the HRD/ERBB2 status was associated with improved survival. These findings support HRD as a clinically relevant biomarker in GC/GEJ and justify prospective evaluation of HRD-informed treatment strategies. Research Sponsor: None.

KEYNOTE-811: 6-year median follow-up of pembrolizumab plus trastuzumab and chemotherapy for previously untreated advanced HER2-positive gastric or gastroesophageal junction adenocarcinoma. First Author: Akihito Kawazoe, National Cancer Center Hospital East, Kashiwa, Japan

Background: At the final analysis of the phase 3 KEYNOTE-811 trial (NCT03615326), first-line (1L) pembrolizumab (pembro) plus trastuzumab and chemotherapy (chemo) showed superior OS and consistently improved PFS and ORR with durable responses vs placebo plus trastuzumab and chemo in participants (pts) with HER2-positive (HER2+) advanced or metastatic gastric or gastroesophageal (G/GEJ) adenocarcinoma, particularly in pts with PD-L1 combined positive score (CPS) ≥1 tumors. Results supported the approval of pembro plus trastuzumab and chemo for 1L treatment of advanced or metastatic HER2+ G/GEJ adenocarcinoma with PD-L1 CPS ≥1. We report results after an additional 20 months of follow-up. **Methods:** Eligible pts with untreated advanced or metastatic HER2+ G/GEJ adenocarcinoma, measurable disease, and ECOG PS 0 or 1 were randomly assigned 1:1 to receive pembro 200 mg or placebo IV Q3W for up to 35 cycles plus trastuzumab 6 mg/kg (after loading dose of 8 mg/kg) and chemo (CAPOX or FP). Dual primary end points were OS and PFS per RECIST v1.1 by BICR. Secondary end points included ORR and DOR (per RECIST v1.1 by BICR), and safety. Data cutoff date was November 12, 2025. **Results:** Overall, 698 pts were randomly assigned to the pembro group (n = 350) or placebo group (n = 348). Median follow-up was 70.0 months (range, 50.9-84.2). In the intention-to-treat (ITT) population (all randomly assigned pts), median OS was 20.0 months (95% CI, 17.8-22.1) in the pembro group vs 16.8 months (95% CI, 14.9-18.7) in the placebo group. In pts with PD-L1 CPS ≥1, median OS was 20.1 months (95% CI, 17.9-22.9) vs 15.7 months (95% CI, 13.5-18.5). PFS, ORR, and DOR were also consistent between the ITT population and pts with PD-L1 CPS ≥1 (Table). Treatment-related AEs occurred in 341 pts (97.4%; grade ≥3, 206 [58.9%]) in the pembro group and 335 (96.8%; grade ≥3, 177 [51.2%]) in the placebo group. **Conclusions:** Pembro plus trastuzumab and chemo continued to show improved OS, PFS, and ORR vs placebo plus trastuzumab and chemo after a median study follow-up of 70 months, especially in pts with PD-L1 CPS ≥1. No new safety signals were seen. The findings continue to support pembro plus trastuzumab and chemo as the preferred 1L treatment for advanced or metastatic HER2+ G/GEJ adenocarcinoma. Clinical trial information: NCT03615326. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Efficacy and safety of PD-1 inhibitor plus chemotherapy vs chemotherapy alone in advanced gastric cancer patients with low or negative PD-L1 expression. First Author: Abdallah Al Ghnaimat, Hashemite University, Department of Medicine, Zarqaa, Jordan

Background: Advanced gastric and gastroesophageal junction (GEJ) adenocarcinoma remains a major global health challenge with limited treatment options and poor prognosis in metastatic or unresectable disease. Immune checkpoint inhibitors targeting the programmed death-1 (PD-1) pathway, when combined with standard chemotherapy, have improved outcomes in overall populations, as shown in pivotal trials such as CheckMate-649 and KEYNOTE-859. However, efficacy is strongly influenced by tumor PD-L1 expression, with patients exhibiting low or negative PD-L1 expression (combined positive score [CPS] <1 or <5, or tumor area positivity [TAP] $<5\%$) derive less pronounced benefit. Subgroup analyses from ORIENT-16 and RATIONALE-305 show heterogeneous results, leaving uncertainty regarding the benefit of PD-1 inhibitors in this subgroup. We aimed to evaluate the efficacy and safety of first-line PD-1 inhibitor–chemotherapy combinations versus chemotherapy alone in this clinically important population. **Methods:** A systematic search of PubMed/MEDLINE, Embase, Cochrane Library, Scopus, ClinicalTrials.gov, and major oncology conferences was conducted through January 16, 2026. We included Phase III randomized controlled trials comparing PD-1 inhibitor plus chemotherapy with chemotherapy alone in adults with treatment-naïve advanced gastric or GEJ adenocarcinoma and low/negative PD-L1 expression (CPS <1, <5, or TAP $<5\%$). Meta-analyses were conducted using RevMan 5.4 with the generic inverse variance method for time-to-event outcomes (HR) and Mantel–Haenszel method for dichotomous outcomes (RR). Heterogeneity was assessed using I^2. Primary outcomes were overall survival (OS) and progression-free survival (PFS); secondary outcomes included objective response rate and safety. **Results:** Four Phase III RCTs (CheckMate-649, KEYNOTE-859, ORIENT-16, RATIONALE-305) comprising 4,761 patients were included. Subgroup data from patients with low/negative PD-L1 expression were analyzed. PD-1 inhibitors did not improve OS (HR 0.92, 95% CI 0.81–1.03, P=0.16; I^2=0%) or PFS (HR 0.84, 95% CI 0.70–1.02, P=0.08; I^2=47%). Results were consistent across CPS and TAP methods. Toxicity was significantly increased, with higher grade $\geq$3 adverse events (RR 1.48, P$<$0.001) and immune-related adverse events (any grade RR 2.80; grade $\geq$3 RR 4.30). **Conclusions:** In advanced gastric/GEJ adenocarcinoma with low/negative PD-L1 expression, first-line PD-1 inhibitor plus chemotherapy provides no survival benefit and substantially increases toxicity. These findings support biomarker-guided treatment selection and highlight the need for alternative therapeutic strategies. Research Sponsor: None.

Characterization and management of gastrointestinal (GI) adverse events (AEs) with zanidatamab + chemotherapy (CT) ± tislelizumab in first-line (1L) HER2-positive (HER2+) locally advanced or metastatic gastroesophageal adenocarcinoma (mGEA): Analysis from HERIZON-GEA-01. First Author: Elena Elimova, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: In HERIZON-GEA-01, replacing 1L trastuzumab (tras) + CT with zanidatamab + CT ± tislelizumab significantly improved progression-free survival and, with tislelizumab, yielded a statistically significant overall survival benefit in HER2+ mGEA. The safety profile was manageable; diarrhea was the most common AE. Here we further characterize GI AEs and diarrhea management. **Methods:** Eligible patients (pts) with previously untreated HER2+ mGEA were randomized 1:1:1 to zanidatamab (1800 mg [$<$70 kg]/2400 mg [$\geq$70 kg] IV Q3W) + tislelizumab (200 mg IV Q3W) + capecitabine/oxaliplatin (CAPOX) or 5-FU/cisplatin (FP); zanidatamab + CAPOX or FP; or tras + CAPOX or FP. CT could be discontinued per physician preference after cycle 6. Tras dose reductions were not permitted. Diarrhea prophylaxis (loperamide 4 mg orally BID) was mandatory in zanidatamab-containing arms for the first 7 days of cycle 1. **Results:** Median treatment duration was 43.1 wk with zanidatamab + tislelizumab + CT, 31.0 with zanidatamab + CT, and 30.0 with tras + CT. Median number of CT cycles was 6, 6, and 7, respectively. Diarrhea was the most common GI AE in all arms; other GI AEs were generally similar across arms. Among pts who experienced diarrhea, most had first onset in cycle 1 (76% in $\leq$3 wk) with median duration $<$2.5 wk (Table). Few pts had their first onset of diarrhea occur after cycle 6 when pts could discontinue CT. HER2-targeted therapy discontinuations (4.1%, 1.3%, 0.3%, respectively) and dose reductions (9.9%, 10.8%, NA) or delays (13.6%, 13.4%, 7.6%) due to diarrhea were infrequent. Diarrhea was more often managed with CT dose reduction (21.8%, 23.6%, 14.2%, respectively). Immune-mediated colitis occurred in 2.7% of pts with zanidatamab + tislelizumab + CT. Additional incidence and management data will be presented. **Conclusions:** In zanidatamab-treated pts, most diarrhea events were grade 1/2, and first-onset events tended to occur in cycle 1 and resolved in $<$3 wk. Diarrhea rarely led to zanidatamab discontinuation. The safety of zanidatamab-containing regimens appears favorable given the survival benefits; diarrhea should be managed with prophylactic loperamide and CT dose modifications as needed. Clinical trial information: NCT05152147. Research Sponsor: Jazz Pharmaceuticals; BeOne Medicines; Zymeworks Biopharmaceuticals.

Clinicopathologic and molecular features of Krukenberg tumors from gastric cancer (GC): A single-institution experience. First Author: Nancy Nguyen, Department of Internal Medicine, Alameda Health System - Highland Hospital, Oakland, CA

Background: Krukenberg tumors (KTs), ovarian metastases most commonly arising from gastric adenocarcinoma, represent an aggressive and understudied metastatic phenotype, frequently associated with diffuse-type gastric cancer (GC). The molecular determinants underlying this metastatic pattern remain poorly characterized. We aimed to define the clinicopathologic and genomic landscape of GC-associated KTs. **Methods:** We conducted a retrospective review of 103 patients with metastatic gastric or gastroesophageal junction adenocarcinoma treated at City of Hope (2020–2025). Twenty-two patients with confirmed KTs were identified. Clinicopathologic data were extracted from electronic medical records. Next-generation sequencing (NGS) for KTs was performed on primary or metastatic tumor specimens. Survival outcomes were estimated using the Kaplan-Meier method, with progression-free survival (PFS) and overall survival (OS) reported with 95% confidence intervals (CIs). **Results:** The median age at diagnosis was 45 years (range, 30–64). HER2 positivity was infrequent (14%), and PD-L1 expression was heterogeneous across tumors. Genomic profiling demonstrated recurrent alterations in *TP53* (53%), *ARID1A* (20%), *CDH1* (13%), *KRAS* (13%), and *PIK3CA* (13%). Notably, 86.4% of KTs exhibited CLDN18.2 immunohistochemical expression $>$ 75%, and 80% of patients had low PD-L1 CPS scores ($<$ 5). The CLDN18::ARHGAP26 fusion was detected in 30% of sequenced tumors, representing a highly recurrent structural alteration. Median PFS was 9 months (95% CI, 4–15), and median OS was 17 months (95% CI, 5–30). **Conclusions:** GC–associated KTs demonstrate a distinct molecular architecture enriched for diffuse-type genomic features, including frequent *TP53* mutations and recurrent CLDN18::ARHGAP26 fusions, aligning with the poor prognosis observed in this cohort. Our findings establish CLDN18 fusions as a recurrent molecular hallmark of GC–associated ovarian metastases, providing novel clinicopathologic insight into mechanisms of ovarian metastatic tropism. Importantly, the high prevalence of CLDN18.2 protein expression identifies a biologically actionable therapeutic vulnerability. CLDN18.2-directed strategies may represent an effective biomarker-driven treatment approach capable of achieving disease control without reliance on surgical intervention. These data define a high-risk, biologically distinct metastatic phenotype and support precision-guided therapeutic targeting, in this clinically aggressive patient population. SYS6010 combined with SYH2051 in advanced solid tumors: Results from a phase Ib/II trial. First Author: Rongbo Lin, Department of Gastrointestinal Medical Oncology, Fujian Cancer Hospital, Fuzhou, China

Background: SYS6010 is an antibody-drug conjugate (ADC) composed of an epidermal growth factor receptor (EGFR)-specific antibody, a cleavable linker, and the topoisomerase I inhibitor JS-1. SYH2051 is an ATM inhibitor that disrupts DNA repair. The combination of SYS6010 and SYH2051 has shown preliminary antitumor activity (ASCO 2025) in advanced gastrointestinal tumors, particularly gastric cancer (GC). Here, we report the safety and preliminary efficacy of SYS6010 plus SYH2051 in patients with advanced solid tumors in phase Ib. **Methods:** This was a multi-center, open-label study. Phase Ib enrolled patients with advanced, EGFR-positive or EGFR-mutant solid tumors, including gastric cancer (GC) with EGFR expression ($\geq$1+) in $\geq$30% of tumor cells, who were refractory or intolerant to standard treatment. Phase Ib consisted of dose escalation and expansion parts. Dose escalation followed a 3+3 design, exploring SYS6010 at doses of 3.2 mg/kg and 3.6 mg/kg (both Q2W) in combination with SYH2051 at 20 mg, 40 mg, 60 mg, and 80 mg (QD). The primary endpoints were safety, maximum tolerated dose (MTD), and recommended phase II dose (RP2D). **Results:** As of October 31, 2025, a total of 117 patients (median age, 58 years; male, 73.5%; ECOG PS 1, 72.6%; metastasis, 100%) were enrolled. Most common tumor types included gastric cancer (GC, n = 66), colon cancer (n = 24), and rectal cancer (n = 15). One dose-limiting toxicity (grade 4 thrombocytopenia) was reported in the regimen of SYS6010 3.2 mg/kg plus SYH2051 60 mg. The RP2D was determined to be SYS6010 3.6 mg/kg plus SYH2051 40 mg. Overall, 94.0% (110/117) of enrolled patients reported at least one treatment-related adverse event (TRAE). The common TRAEs ($\geq$30%) were anemia (68.4%), leukopenia (50.4%), neutropenia (48.7%), decreased appetite (47.0%), nausea (43.6%), hypoalbuminemia (40.2%), fatigue (39.3%), and thrombocytopenia (33.3%). Grade $\geq$ 3 TRAEs occurred in 44.4% (52/117) of patients. Treatment discontinuations due to TRAEs were reported in 0.9% (1/117) of patients for SYS6010 and in 0.9% (1/117) for SYH2051. No deaths were reported due to TRAEs. Among all efficacy-evaluable GC patients treated with the RP2D regimen (n = 33), the confirmed objective response rate (cORR) was 15.2%, disease control rate (DCR) was 69.7%, and median progression-free survival (mPFS) was 4.5 mo (95% CI, 2.1–5.7). For the 17 patients receiving RP2D regimen as $\geq$3rd-line therapy, cORR was 23.5%, DCR was 88.2%, and mPFS was 5.4 mo (95% CI, 2.5–NR). The 3-mo and 6-mo PFS rates were 72.4% and 36.2%, respectively. Overall survival data were immature. **Conclusions:** The combination of SYS6010 and SYH2051 showed acceptable safety and tolerability in patients with advanced solid tumors. Promising antitumor activity was observed in patients with advanced GC, particularly among those receiving the regimen as $\geq$3rd-line therapy. Clinical trial information: NCT07104877. Efficacy and safety of tecotabart vedotin plus toripalimab with or without chemotherapy as first-line treatment for CLDN18.2-positive advanced gastric or gastroesophageal junction adenocarcinoma: Phase II study results. First Author: Jin Li, China Pharmaceutical University Shanghai GoBroad Cancer Hospital, Shanghai, China

Background: Tecotabart vedotin (TV; LM-302) is a novel and potent MMAE-based ADC targeting CLDN18.2. Previous data (ASCO 2025, abstract#4039) demonstrated promising efficacy and manageable safety profile of TV plus PD-1 inhibitor in patients (pts) with systemic therapy-naive advanced gastric or gastroesophageal junction (G/GEJ) cancer. Updated phase II results of TV plus toripalimab (T) with or without chemotherapy in this first-line setting are presented. **Methods:** Eligible pts had histologically confirmed, no prior systemic therapy, HER2-negative G/GEJ adenocarcinoma with CLDN18.2 positivity (IHC 2+/3+ in ≥1% of tumor cells). Pts received TV (1.8 mg/kg Q2W) plus T (3 mg/kg Q2W), with or without capecitabine or S-1. The primary endpoint was PFS per RECIST v1.1. Secondary endpoints were efficacy, safety, PK, and biomarker analysis. Data cutoff: November 25, 2025. **Results:** A total of 71 pts with G/GEJ adenocarcinoma were enrolled: 39 in the TV+T cohort and 32 in the TV+T+Chemo cohort. Baseline CLDN18.2 high expression (≥25%) was presented in 82.1% of pts in the TV+T cohort and 84.4% in the TV+T+Chemo cohort. PD-L1 CPS ≥1 was observed in 61.5% and 81.3% of pts, respectively. Median follow-up was 16.16 months in the TV+T cohort and 14.82 months in the TV+T+Chem cohort. The median PFS (95% CI) was 10.68 months (6.28, NE) and 12.55 months (6.80, NE), respectively. Among pts with CLDN18.2 ≥25%, the median PFS (95% CI) was 12.22 months (6.87, NE) and NE (8.44, NE), the median DOR (95% CI) was 13.86 months (9.36, NE) and NE (7.10, NE), ORR was 64.5% and 69.2%, and DCR was 96.8% and 96.2%, respectively. Median OS was not reached in either cohort. In pts with CLDN18.2 <25%, TV+T (N=7) and TV+T+Chemo (N=5) showed a median PFS (95% CI) of 5.72 (1.15, NE) and 6.80 (5.55, NE) months, ORR of 14.3% and 40.0%, DCR of 71.4% and 100%, and OS (95% CI) of 10.78 (2.56, NE) months and NE (8.25, NE), respectively. TRAEs occurred in all pts. Grade ≥3 TRAEs occurred in 66.7% of pts in the TV+T cohort and 81.3% of pts in the TV+T+Chemo cohort. The most common Grade ≥3 TRAEs (incidence ≥20%) were decreased neutrophil count in the TV+T cohort, and decreased neutrophil count and decreased white blood cell count in the TV+T+Chemo cohort. TEAEs leading to dose reduction occurred in 17.9% (Grade ≥3: 12.8%) and 43.8% (Grade ≥3: 18.8%) of pts, respectively. TEAEs led to treatment discontinuation occurred in 15.4% (Grade ≥3: 7.7%) and 31.3% (Grade ≥3: 28.1%), respectively. No treatment-related deaths were reported. **Conclusions:** TV+T, with or without chemotherapy, demonstrated encouraging anti-tumor activity and manageable safety as first-line treatment for CLDN18.2-positive advanced G/GEJ cancer. The doublet shows comparable efficacy to the triplet with enhanced tolerability, supporting further large-scale clinical investigation. Clinical trial information: NCT05934331. Research Sponsor: LaNova Medicines Limited.

Phase II trial of SYS6010, an EGFR antibody-drug conjugate (ADC) in patients with advanced esophageal squamous cell carcinoma (ESCC). First Author: Rongbo Lin, Department of Gastrointestinal Medical Oncology, Fujian Cancer Hospital, Fuzhou, China

Background: SYS6010 is an EGFR- ADC composed of an EGFR-specific antibody, a cleavable linker, and the topoisomerase I inhibitor (TOPOi) JS-1. Preliminary clinical data from the phase I study of SYS6010 monotherapy in patients with solid tumors showed an acceptable safety and encouraging preliminary efficacy (ChiCTR2300072141). Here, we report the efficacy and safety results of SYS6010 in patients with ESCC in the phase II trial. **Methods:** Patients with advanced ESCC that was refractory or intolerant to standard therapy were enrolled. In the dose-expansion part, SYS6010 was administered intravenously at a dose of 3.6 mg/kg every 2 weeks (Q2W). The primary endpoint was objective response rate (ORR) assessed by the investigator. **Results:** As of Jan 14, 2026, 48 patients with ESCC (median age, 64.5 years; male, 89.6%; ECOG PS 1, 87.5%; metastatic disease, 93.8%) were enrolled and received SYS6010. Ten patients (20.8%) had received ≥3 prior lines of systemic therapy. The median follow-up was 3.9 months (mo; Q1-Q3: 3.1-5.6). Among 40 efficacy-evaluable patients, the confirmed ORR (cORR) was 35% (95%CI 20.6-51.7), and the disease control rate (DCR) was 67.5% (95%CI 50.9-81.4). Median progression-free survival (mPFS) was 4.6 mo (95% CI, 2.7–NR; 48% maturity). The 3-mo and 6-mo PFS rates were 56.3% and 41.4%, respectively. 15 patients remain on treatment with SYS6010. For TOPOi-naïve patients (n = 34), cORR and DCR were 41.2% (95%CI 24.7-59.3) and 70.6% (95%CI 52.5-84.9), respectively. mPFS was 4.6 mo (95%CI 2.8-NR; 45% maturity), with 3-mo and 6-mo PFS rates of 62.5% and 43.2%, respectively. 14 patients remain on treatment with SYS6010. Overall, 97.9% (47/48) of patients experienced treatment-related adverse events (TRAEs). Grade ≥3 TRAEs occurred in 31 (64.6%) patients. Common grade ≥3 TRAEs (≥5%) included neutropenia (29.2%), anemia (18.8%), leukopenia (18.8%), thrombocytopenia (12.5%), lymphocytopenia (8.3%), vomiting (8.3%), and nausea (6.3%). TRAEs led to treatment discontinuation in 4 (8.3%) patients. One death of unknown reason was reported and assessed by the investigator as related to the study drug. **Conclusions:** SYS6010 demonstrated a manageable safety profile and promising antitumor activity, supporting further development in patients with advanced ESCC, especially TOPOi-naïve patients. A phase 3 study is planned to compare SYS6010 with standard of care (SOC) in patients with TOPOi-naïve ESCC. Clinical trial information: ChiCTR2500099933. Research Sponsor: CSPC Megalith Biopharmaceutical Co., Ltd.

Cadonilimab in combination with ivonescimab and chemotherapy as first-line (1L) therapy in patients with advanced gastric (G) or gastroesophageal junction adenocarcinoma (GEJA): Updated results from an open-label phase II trial. First Author: Guangyu Wang, The Affiliated Cancer Hospital of Harbin Medical University, Harbin, China

Background: Cadonilimab (AK104), an anti-PD-1/CTLA-4 bispecific antibody, plus chemotherapy significantly improved OS versus chemotherapy and had a tolerable safety profile in first-line (1L) treatment of advanced G/GEJA patients (pts), including those with low PD-L1 expression. Currently, it has been approved by NMPA. Ivonescimab (AK112), also approved in China, is a novel bispecific antibody against PD-1 and VEGF and has shown a clinically significant improvement in efficacy with favorable safety for advanced NSCLC in two phase 3 studies (HARMONi-2 and HARMONi-A). Here, we presented the updated data for the safety and efficacy of AK104 combined with AK112 and chemotherapy as 1L treatment in advanced G/GEJA. **Methods:** Pts with previously untreated advanced G/GEJA were enrolled. The phase II trial consisted of a dose-escalation part (part 1) and a dose expansion part (part 2). Eligible pts were firstly enrolled into sequential part1 including 10mg/kg and 15mg/kg AK104 (Q6W, D8) combined with AK112 (20mg/kg, Q3W, D1) and chemotherapy (SOX or XELOX) following the conventional 3+3 design. If the starting dose of 10mg/kg AK104 led to ≥2 dose-limiting toxicities (DLTs), 6mg/kg AK104 would be administered. After the part 1 completed, eligible pts were enrolled into the part 2 and received AK104 (the recommended dose, Q6W, D8) combined with AK112 (20 mg/kg, Q3W, D1) and chemotherapy (SOX or XELOX). The primary outcomes were safety and ORR. Secondary endpoints included DCR, PFS, OS, biomarkers of drug activity and pharmacokinetics. **Results:** As of 19 January 2026, 54 pts were enrolled with a median age of 60 years (range: 39-75). 55.6% were PD-L1 CPS < 5, 42.6% had liver metastases and 40.7% had peritoneal metastases. Among efficacy evaluable pts, the ORR was 71.7% and DCR was 95.7%. The median PFS (mPFS) was 8.4 months (mo) (95%CI: 6.0-13.1) and OS analysis was immature. In the pts with liver metastases, the ORR was 81.8%, DCR was 90.9% and mPFS was 10.7 mo (95%CI: 5.7-13.1). In the pts with peritoneal metastases, the ORR was 72.2%, DCR was 100.0% and mPFS was 6.4 mo (95%CI: 5.45-NR). Grade 3-4 treatment-related adverse events (TRAEs) were reported in 18.5% pts, mainly including hypokalemia (5.6%), decreased neutrophil count (3.7%), decreased platelet count (3.7%) and hyperbilirubinemia (3.7%). There were no grade 4/5 TRAEs or treatment-related deaths. **Conclusions:** Updated results demonstrated that AK104 combined with AK112 and chemotherapy as 1L treatment continued to show highly encouraging anti-tumor activity with a manageable safety profile in pts with advanced G/GEJA, including those with liver or peritoneal metastases. Clinical trial information: NCT06196697. Research Sponsor: None.

4050 **Poster Session**

Molecular circulating tumor DNA (ctDNA) profiling from patients (pts) treated with zanidatamab + chemotherapy (CT) in first-line (1L) HER2-positive (HER2+) advanced or metastatic gastroesophageal adenocarcinoma (mGEA). First Author: Elena Elimova, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Zanidatamab is a dual HER2-targeted bispecific antibody that binds to HER2 extracellular domains 2 and 4. In the phase 3 HERIZON-GEA-01 trial, 1L zanidatamab ± tislelizumab + CT significantly prolonged progression-free survival (PFS) and, with tislelizumab, yielded significant overall survival benefits versus trastuzumab + CT in HER2+ mGEA. Consistent results were previously reported in a phase 2 trial of zanidatamab + CT. ctDNA profiling provides a noninvasive approach to identify pts who could benefit from HER2-targeted therapies, and on-treatment ctDNA reductions may be associated with response. Here we report ctDNA profiling from the phase 2 trial. **Methods:** The phase 2 trial (NCT03929666) evaluated zanidatamab + CT (mFOLFOX6, CAPOX, or 5-FU/cisplatin [FP]) in 1L mGEA. Pts in part 1 had HER2-expressing (IHC 3+ or 2+) mGEA. Pts in part 2 had HER2+ (IHC 3+ or IHC 2+/FISH+) mGEA by central assessment (ccHER2+). Primary endpoint was confirmed objective response rate (cORR). PFS was a secondary endpoint. Plasma ctDNA samples were collected prior to cycle 1 of zanidatamab (baseline [BL]) and on treatment (cycle 2 day 15 for zanidatamab + CAPOX or FP; cycle 3 day 1 for zanidatamab + mFOLFOX6) for NGS by Guardant360 and/or Guardant Infinity. **Results:** 46 pts were enrolled (zanidatamab + mFOLFOX6 [n = 24], CAPOX [n = 20], FP [n = 2]). Most (41 [89%]) pts had ccHER2+ mGEA. cORR was 76.2% (95% CI 60.5, 87.9) and median PFS was 12.5 (95% CI 8.2, 21.8) mo. BL ctDNA was available from 39 pts; 29 had on-treatment samples, and 16 had matched BL and on-treatment samples. The concordance was 94% (34/36) between centrally assessed *ERBB2* amplification by FISH in tissue and *ERBB2* amplification in plasma ctDNA by NGS. Among 34 pts with detectable *ERBB2* amplification at BL, median PFS was 18.6 (95% CI 12.0, NE) mo. All pts with available samples and confirmed complete (CR) or partial (PR) response or stable disease (SD) had undetectable on-treatment *ERBB2* amplification in ctDNA. Most pts with *ERBB2* indel, fusion, or SNV (79% [15/19]) or with *PIK3CA* amplification or SNV (86% [12/14]) at BL had CR or PR. Nearly all (94% [15/16]) pts with available matched samples had a > 80% decrease in ctDNA from BL to on-treatment assessment on the Guardant Infinity panel. On-treatment ctDNA samples from pts with progressive disease or SD showed recurrence/persistence of *ERBB2* alterations and co-alterations across PI3K/AKT and RAS/MAPK pathways. Additional data will be presented. **Conclusions:** Molecular ctDNA profiling showed that 1L zanidatamab + CT in HER2+ mGEA could markedly reduce total ctDNA levels and *ERBB2* amplification detection early in treatment. Antitumor activity was observed among pts whose tumors harbored *ERRB2* and *PIK3CA* mutations, both of which are associated with resistance to standard HER2-targeted therapies. Clinical trial information: NCT03929666. Research Sponsor: Jazz Pharmaceuticals; Zymeworks Biopharmaceuticals.

4051 **Poster Session**

Survival outcomes according to ramucirumab (RAM)-related hypertension (HTN) in patients (pts) with advanced HER2-negative gastric (G) or gastroesophageal junction (GEJ) cancer: An exploratory analysis of the phase III ARMANI trial. First Author: Roberta Fazio, Medical Oncology Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, NA, Italy

Background: Retrospective studies suggest an association between treatment-related HTN and improved outcomes with anti-angiogenic agents, with most evidence derived from colorectal cancer pts treated with bevacizumab. Data on the prognostic significance of RAM-induced HTN are limited. We therefore explored the association between treatment-related HTN and survival outcomes in the ARMANI trial. **Methods:** ARMANI was a phase III trial enrolling pts with advanced HER2-negative G/GEJ cancer who had disease control after a 3-month first-line fluoropyrimidine and oxaliplatin (FOX) induction chemotherapy. Pts were randomized to switch maintenance with paclitaxel plus RAM (PTX-RAM) or the continuation of FOX. The objectives of this exploratory analysis were to evaluate the association between grade (G)≥2 HTN and survival outcomes across treatment arms (using the FOX arm as reference [ref]) and within the PTX–RAM arm. To mitigate time-related bias, Cox proportional hazards models were fitted with HTN modeled as a time-dependent covariate, considering pts 'non-HTN' until G≥2 HTN onset and 'HTN' thereafter. Because HTN is a post-randomization event, survival analyses in the PTX-RAM arm by HTN status were adjusted for baseline characteristics using inverse probability weighting based on propensity scores derived from a logistic regression model. **Results:** Among 276 pts (141 in PTX-RAM and 135 in FOX arm), G≥2 HTN occurred in 20 cases (7.2%), all observed in the PTX-RAM arm (20/141, 14.2%). The incidence of G≥2 HTN was similar between males and females (15.8% versus 10.9%) and between pts aged < 70 and ≥70 years (14.4% versus 13.5%). Median time to G≥2 HTN-onset was 3 months. In the between-arm comparison, the PTX–RAM arm showed improved progression-free survival (PFS) versus FOX regardless of HTN development (p = 0.192). In contrast, the overall survival (OS) benefit was greater in the HTN group (p = 0.071). These findings are detailed in the Table below. In analyses restricted to the PTX–RAM arm, G≥2 HTN onset was associated with improved OS (HR 0.43; 95% CI, 0.22-0.83; p = 0.033), whereas no significant difference was observed for PFS (HR 0.88; 95% CI, 0.50-1.57; p = 0.735). **Conclusions:** The development of G≥2 HTN was associated with a significant OS benefit in pts treated with PTX–RAM in the ARMANI trial. These findings support further research to identify biomarkers predictive of HTN onset to refine pts selection for switch maintenance strategies. Clinical trial information: NCT02934464. Research Sponsor: None.

	Median PFS (months) (95% CI)	HR (95% CI)	Median OS (months) (95% CI)	HR (95% CI)

Genomic biomarkers of primary resistance to anti-EGFR monoclonal antibodies (mAbs) by comprehensive genomic profiling (CGP) in *EGFR*-amplified (ampl) advanced gastroesophageal adenocarcinoma (aGEA) and correlative analysis from a single-arm study with panitumumab. First Author: Cecilia Villa, Medical Oncology Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, NA, Italy

Background: *EGFR* ampl is found in up to 6% of patients with aGEA and accounts for the efficacy of anti-EGFRs in this patients' subgroup. The AMNESIA panel with *KRAS*/*PIK3CA*/*MET* mutations and *KRAS*/*EGFR*/*MET* amplifications represented a paradigm of negative selection to trastuzumab in HER2+ aGEA. Here, we aimed to characterize the prevalence and prognostic relevance of genomic drivers of primary resistance to EGFR blockade in *EGFR*-ampl aGEA. **Methods:** Patients with *EGFR*-ampl aGEA were retrieved from 3 CGP screening sources, i.e. the ARMANI phase 3 trial, an observational cohort established at the Fondazione IRCCS Istituto Nazionale dei Tumori (INT) of Milan and 11 patients with *EGFR* ISH positive aGEA treated with panitumumab as ≥2L from the 117/15 INT screening platform (thereafter Panitumumab study). CGP was performed by means of FoundationOne CDx next-generation sequencing (NGS). AMNESIA-EGFR panel grouped genomic alterations with clinical and biological rationale as driver of primary resistance to anti-EGFR mAbs, i.e. *EGFR* rearrangements, *FGFR2*/*HER2*/*MET*/*RAS* co-ampl, *RAS*/*MEK1*/*PIK3CA* ex20 mut, *AKT1/2* mut and *PTEN* loss. We evaluated prevalence of AMNESIA-EGFR alterations in the ARMANI and observational cohort. Then, we explored the prognostic impact of AMNESIA-EGFR panel and lack of *EGFR* ampl by NGS in the Panitumumab study. **Results:** *EGFR*-ampl by NGS was found in 3/130 (2.3%) and 7/128 (5.5%) pts in the ARMANI and observational cohort. *EGFR* ampl was confirmed by NGS in 8/11 pts (73%) in the panitumumab cohort. Among patients with *EGFR*-ampl tumors by NGS, AMNESIA-EGFR alterations were found in 9/18 (50%) pts, including: *KRAS* ampl (16.7%), *EGFR* rearrangement (11.1%), *PTEN* loss (11.1%), *FGFR2* co-ampl (5.6%), *MET* co-ampl (5.6%) and *MEK1* mut (5.6%). AMNESIA-EGFR panel alterations were mutually exclusive, except for one case with concurrent *MET* co-ampl and *MEK1* mutation. In the Panitumumab study, disease control rate (DCR) was 18.2% including a partial response and a stable disease. Median progression-free survival (PFS) and overall survival (OS) were 2.0 months (95%CI, 1.8-NA) and 5.3 months (95%CI, 3.38-NA). 7/11 pts had tumors with AMNESIA-EGFR alterations or lacked *EGFR* ampl by NGS. AMNESIA-EGFR+ or lack of *EGFR* ampl were associated with inferior DCR (0% vs 50%), PFS (median PFS 2.0 vs 3.8 months; HR 3.17 [95% CI, 0.64-NA] and OS (median OS 5.3 vs 6.4 months; HR 1.80 [95%CI, 0.45–7.14]). **Conclusions:** Genomic drivers of primary resistance to anti-EGFR mAbs are common in *EGFR*-ampl aGEA. A negative selection paradigm based on CGP may optimize outcomes with anti-EGFRs. Innovative drugs that may bypass resistance mechanisms to mAbs, such as bispecific antibodies, antibody-drug conjugates and bispecific T-cell engagers, are awaited. Research Sponsor: None.

Real-world treatment patterns and overall survival (OS) in patients (pts) with HER2-positive (HER2+) advanced or metastatic gastroesophageal adenocarcinomas (mGEA) in the US. First Author: Farshid Dayyani, UC Irvine Health, Orange, CA

Background: The first-line (1L) standard of care for pts with HER2+ mGEA is HER2-targeted therapy (HER2 Tx) plus platinum-based chemotherapy (CT). Recent immunotherapy (IO) addition to this regimen prolonged OS of pts with HER2+ programmed death-ligand 1 (PD-L1)-positive (PD-L1+) mGEA. Here, we describe real-world treatment patterns and OS in pts with HER2+ mGEA in the US since the FDA approval of 1L IO. **Methods:** Adults with HER2+ mGEA who initiated 1L systemic therapy between May 2021 and 2025 and had ≥6 mo of follow-up (or died within 6 mo) after 1L initiation, were identified from the Flatiron Health Electronic Health Records database. OS from 1L initiation was evaluated with the Kaplan-Meier method in the overall HER2+ cohort and in a subset of pts with PD-L1+ disease. Outcomes were also reported with HER2 Tx + CT ± IO use. **Results:** Of 2237 pts with known HER2 status prior to 1L therapy, 21% were HER2+, defined as immunohistochemistry (IHC) 3+, IHC 2+/*ERBB2*-amplified, or per physician's note. Mean (SD) age was 66.1 (11.7), 20% of pts were female, and 66% had an Eastern Cooperative Oncology Group performance status ≤1. Of 292 pts with HER2+ mGEA and known PD-L1 status prior to 1L, 81% were PD-L1+ (combined positive score ≥1 or per physician's note). Of the 467 pts with HER2+ mGEA who received 1L therapy, 60% had HER2 Tx, 28% had CT alone, and 10% received IO-based regimens without HER2 Tx. Of the 281 pts on 1L HER2 Tx, 58% had HER2 Tx + IO + CT and 37% had HER2 Tx + CT. Overall, 228/467 (49%) pts treated in the 1L went on to receive second-line (2L) therapy. In the 2L setting, 70% of pts received HER2 Tx, including 38% pts who only received CT or IO-based regimens without HER2 Tx in 1L treatment. A total of 42% of pts on 2L therapy received 1L and 2L HER2 Tx. Among the 467 pts with HER2+ mGEA, median OS (mOS) from 1L initiation was 17.4 mo. In the PD-L1+ subgroup, mOS was 19.0 mo in pts on HER2 Tx + IO + CT, and 17.2 mo in pts on HER2 Tx + CT without IO (Table). Across treatment groups, mOS remained <2 years, and the 24-mo OS rate was <40%. **Conclusions:** Despite the availability of HER2 Tx, a significant unmet need remains, as 40% of pts with HER2+ mGEA did not receive this option in 1L regimens. OS was numerically longer with HER2 Tx + IO + CT vs without IO in the HER2+/PD-L1+ mGEA subgroup. These data underscore the need to improve OS and the opportunity to enhance biomarker-guided management of HER2+ mGEA. Research Sponsor: Jazz Pharmaceuticals.

Updated results of benmelstobart plus anlotinib combined with SOX in the first-line treatment of advanced gastric or gastroesophageal junction (G/GEJ) adenocarcinoma with low PD-L1 expression: A single-arm, multicenter phase II clinical trial. First Author: Yong-Xu Jia, Department of Oncology, Zhengdong Campus, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

Background: While PD-1 inhibitors plus chemotherapy have become standard first-line therapy for advanced HER2-negative gastric/gastroesophageal junction (G/GEJ) adenocarcinoma, patients with low PD-L1 expression (Combined Positive Score (CPS) < 5) derive limited benefit. Anti-angiogenic agents can modulate the tumor immune microenvironment and synergize with immune checkpoint inhibitors. Anlotinib, a multi-targeted tyrosine kinase inhibitor approved in China, offers a promising combination strategy. This study evaluates the efficacy and safety of benmelstobart (a PD-L1 inhibitor) combined with anlotinib and SOX (S-1 plus oxaliplatin) as first-line therapy in patients with advanced G/GEJ adenocarcinoma and low PD-L1 expression. **Methods:** Patients with HER2-negative, unresectable, locally advanced, or metastatic G/GEJ adenocarcinomas and PD-L1 CPS < 5, who had not received prior systemic therapy were included. They received benmelstobart (1200mg, iv, d1, q3w) combined with anlotinib (10mg, po, d1~14, q3w), oxaliplatin (130mg/m^2 , d1, iv, q3w) and S-1 (40mg, po, bid, d1~14, q3w) for 6 cycles as initial therapy. Maintenance therapy with benmelstobart (1200mg, iv, d1, q3w) plus anlotinib (10mg, po, d1~14, q3w) followed for non-progressive disease until PD or unacceptable toxicity occurred. Tumor responses were evaluated by RECIST 1.1 criteria. The target sample size was 37, with ORR as the primary endpoint, and safety, DCR, DoR, PFS, and 1-year OS rate as secondary endpoints. **Results:** From June 2023 to June 2025, 37 patients were enrolled. At the data cut-off date (December, 2025), the best overall response indicated that there were 31 PR (83.8%) and 6 SD (16.2%). Therefore, the preliminary ORR was 83.8% (95%CI: 68-93.8), DCR was 100% (95%CI: 90.5-100). The preliminary prognostic result exhibited that the median PFS of the 37 patients was 11.3 months (95%CI: 8.07-14.53). The 1-year OS rate was 91.33% (95%CI: 75.46–97.12). Safety was manageable, common TRAEs > 20% included platelet count decreased (54.1%), white blood cell decreased (32.4%), anemia (24.3%). **Conclusions:** The combination of benmelstobart, anlotinib, and SOX demonstrated promising efficacy with a manageable safety profile as first-line therapy for advanced G/GEJ adenocarcinoma with low PD-L1 expression. These findings warrant validation in larger cohorts. Clinical trial information: NCT06939452. Research Sponsor: None.

Nimotuzumab combined with paclitaxel and cisplatin as first-line treatment for metastatic esophageal squamous cell carcinoma: A prospective, multicenter, double-blind, randomized controlled clinical study. First Author: Zhihao Lu, Beijing Cancer Hospital, Beijing, China

Background: Chemotherapy for advanced esophageal squamous cell carcinoma (ESCC) is limited due to the lack of effective drugs. Such as traditional two drugs chemotherapy (5-Fluorouracil and Cisplatin) as first-line treatment for metastatic and recurrent ESCC has an efficacy of 25-35%. Nimotuzumab is an anti-epidermal growth factor receptor (EGFR) monoclonal antibody. Previous studies have shown that its combination with paclitaxel and cisplatin (TP regimen) has a good efficacy, with an objective response rate (ORR) of up to 55%, median overall survival (mOS) 13.9 months in some small-sample trials. **Methods:** Eligible patients from 36 centers in China, who were randomly assigned to receive nimotuzumab (400 mg once per week, up to 2 years) or placebo followed by TP regimen (paclitaxel 175 mg/m², cisplatin 60 mg/m², Day 1, with a 21-day cycle, up to 6 cycles) until disease progression or unacceptable toxicity. The primary end point was overall survival (OS) and the secondary end points were progression-free survival (PFS), response rates, quality of life (QoL) and safety. **Results:** A total of 640 patients were screened. 503 patients were enrolled and 161 patients with EGFR gene amplification tumors were eligible. In the full analysis set of 497 patients who had took at least one dose of medication, there were no differences in baseline characteristics. The mOS were 12 vs 11.5 months, and the median PFS were 5.6 vs 5.4 months respectively, suggesting survival benefit trend in the trial. ORR were 55.5% and 50.4% for both arms. In the EGFR gene amplification subgroup, the mOS was 13.3 vs 9.5 months (log-rank test, hazard ratio [HR] = 0.66 (95%CI, [0.47-0.93]), P = 0.016) for two groups. Patients who were with ESCC at stage IV, as well as who had not undergone surgery, radical radiotherapy, or neoadjuvant and adjuvant therapy showed significant survival benefits after the addition of nimotuzumab. Median PFS were 6.0 vs 5.5 months for two arms (log-rank test, HR = 0.63 [0.43-0.91], P = 0.014). Both OS and PFS were longer in the nimotuzumab group than in the placebo group. The ORR of the two groups were 61.3% and 44.0%, respectively (P = 0.029). There were no statistically significant differences in the QoL scores of the FAS population at each time point before and after treatment. The incidence of adverse events were comparable in the experimental group and the control group. Such as the incidence of serious adverse event (SAE) was 30.7% and 34.5%, serious adverse drug reaction (SADR) was 2.7% and 8.3%, the incidence of above grade 3 treatment emergent adverse event (TEAE) was 85.3% and 83.3%, respectively, etc. **Conclusions:** In patients with metastatic EGFR gene amplification ESCC, nimotuzumab plus TP as first-line treatment significantly improved OS and PFS with a good safety profile. Research Sponsor: None.

Heterogeneity in biomarkers for advanced gastric cancer, gastroesophageal junction cancer, and esophageal adenocarcinoma (GC/GEJC/EAC) across regions: Insights from CheckMate-649. First Author: Lin Shen, Peking University Cancer Hospital and Institute, Beijing, China

Background: In CheckMate 649, first-line nivolumab plus chemotherapy showed improved clinical efficacy vs chemotherapy in patients (pts) with advanced GC/GEJC/EAC, with varied benefit across regions in a subgroup analysis. To identify biomarkers predictive of differential efficacy outcomes, we did post hoc exploratory biomarker analyses by region. **Methods:** Post hoc exploratory analyses were done with whole-exome sequencing (WES) and RNA-seq of baseline tumor tissue. Pts were grouped by region: China (CN), Asia (including CN), United States + Canada + European Union (UCE), Latin America (LA). For WES-evaluable pts, gene alterations were profiled and pts grouped into genomic subtypes: chromosomal instability (CIN), genomically stable (GS), hypermutated (H), and Epstein–Barr virus (EBV)-positive. Gene expression signatures (GES) related to mitogen-activated protein kinase (MAPK) pathway, stroma, and angiogenesis were assessed by RNA-seq, and pts were stratified into tertiles based on GES score: high, medium, or low. **Results:** Of 1512 pts randomized, 647 were WES-evaluable (79, 141, 351, 155 in CN, Asia, UCE, and LA, respectively) and 769 RNA-evaluable (50, 106, 423, 240, respectively). A numerically lower proportion of CIN subtype and higher proportion of EBV subtype was seen in LA vs other regions (Table). Percentage (%) of select gene alterations was generally comparable across regions: of note, there was numerically higher % of altered *FGFR2* (10%) in CN, altered *TP53* (58%), *KRAS* (16%), *CDKN2A* (11%), and *CDH1* (7%) in UCE, and altered *PIK3CA* (10%) and *ERBB2* (22%) in LA. By contrast, there was numerically lower % of altered *EGFR* (4%) in Asia and altered *ARID1A* (8%) in LA. GES profile was broadly similar across regions, with numerically higher % of MAPK-high subgroup in UCE, stroma-medium/low subgroup in LA, and angiogenesis-low subgroup in CN (Table). **Conclusions:** While the biomarker profile was largely comparable across regions, differential features were noted for certain subgroups; clinical utility of these biomarkers requires validation in future trials. Clinical trial information: NCT02872116. Research Sponsor: Bristol Myers Squibb.

	Regions	CN	Asia(including CN)	UCE	LA

Sintilimab combined with short-course intensified chemotherapy regimen nab-POF in the treatment of metastatic gastric cancer (FDZL-GC002): A single-arm, phase 2 trial. First Author: Weijian Guo, Department of Medical Oncology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China

Background: This prospective phase II study investigates a novel therapeutic strategy combining PD-1 inhibitor sintilimab (Sin) with short-course intensified chemotherapy regimen Nab-POF as first-line treatment for metastatic gastric cancer (MGC), based on the hypothesis that short-duration, high-intensity chemotherapy may potentiate antitumor immunity while reducing the cumulative immunosuppressive burden of prolonged chemotherapy. **Methods:** Eligible patients (pts) received Sin (200mg IV), nab-paclitaxel (125mg/m²), oxaliplatin (85mg/m²), and fluorouracil (2400mg/m² as a 48-hour infusion) (plus trastuzumab for HER2+ pts) Q2W. After 6 cycles, pts without disease progression received maintenance treatment (capecitabine + Sin). Upon disease progression, HER2- pts underwent reinduction with the Nab-POF regimen ± Sin, for up to 6 cycles, followed by maintenance therapy (S-1 +/- Sin). Tumor response was assessed every 3 cycles. PFS1 was defined as the time from informed consent to first progression. PFS2 was defined as the time from consent to second progression. If reinduction therapy was not performed, PFS2 equals to PFS1. The primary endpoint was PFS2 in HER2- pts. **Results:** In total, 123 pts were enrolled up to 09/2025. 118 pts were evaluable. This report presents the results for the HER2- population. Among 90 HER2- pts, the median age was 60 (23-83), with 72.2% male. The common metastatic sites included the liver (36.7%), peritoneum (26.7%), bone (13.3%), and lungs (6.7%). ORR was 82.2% (74/90) and DCR was 100%. Nine pts received complete response and CR rate was 10.0%. 2-year DFS and OS rate were both 100% among pts with CR. 60 pts progressed and 47 patients died. 25 pts experienced reinduction with the Nab-POF regimen ± Sin. Median PFS1 was 13.6mo (95% CI 9.8-16.1) and median PFS2 was 16.2mo (95%CI 11.0-23.2). Median OS was 21.3mo (95% CI 11.3-NR). 1-year OS rate was 72.2% (95%CI 63.5-82.1) and 2-year OS rate was 44.2% (95%CI 33.9-57.6). Subgroup analysis showed whether signet ring cells are present or not, whether liver metastasis occurs or not, and the level of CPS were not related to the therapeutic effect. All pts experienced treatment-related adverse events (AEs). Grade 3/4 AEs were 55.6% (50/90) and neutrophil decrease was the most common at 36.7% (33/90). Immune-related AEs occurred in 22(24.4%) pts, including 6 (6.7%) grade 3/4 events, which were effectively controlled. **Conclusions:** Sin plus short-course intensified chemotherapy regimen Nab-POF demonstrates high response and CR rate, and remarkable long-term effects. This approach may represent a feasible first-line treatment strategy, warranting further evaluation in randomized trials. Clinical trial information: NCT05982301. Research Sponsor: None.

Radiogenomic biomarkers for identifying surgery-sparing candidates in locally advanced gastric or gastro-esophageal junction cancer treated with perioperative immunochemotherapy: A discovery and validation study. First Author: Song-Bin Guo, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China

Background: Perioperative immunochemotherapy has markedly increased pathologic complete remission (pCR) rates in patients with locally advanced gastric cancer or gastroesophageal junction cancer (LAGC/GEJC), raising the possibility of surgery-sparing strategies in selected patients. However, reliable non-invasive tools to identify pCR preoperatively are lacking. This study aimed to develop and validate a radiogenomic model integrating CT radiomics and peripheral blood single nucleotide polymorphism (SNP) data to predict pCR. **Methods:** This retrospective multicenter study included 642 patients with LAGC/GEJC from 14 institutions who received perioperative immunochemotherapy. Patients were assigned to a primary cohort (n = 442; training n = 309, internal validation n = 133) and an external validation cohort (n = 200). Radiomic features were extracted from preoperative CT images, and SNPs were genotyped from peripheral blood. Feature selection was performed using LASSO, generating radiomic (Rad-score) and genomic (Gen-score) signatures. A combined radiogenomic model incorporating Rad-score, Gen-score, and clinical variables was developed using multivariable logistic regression. Model performance was evaluated using AUC and decision curve analysis (DCA). **Results:** Fourteen radiomic features and eight SNPs were selected. The radiogenomic model consistently outperformed single-modality models across cohorts. In the training set, the combined model achieved an AUC of 0.915 (95% CI 0.880–0.950), exceeding Rad-score (AUC 0.832) and Gen-score (AUC 0.798; both $P < 0.001$). In the internal validation set, the AUC was 0.882 (95% CI 0.825–0.939), and in the external validation set, 0.852 (95% CI 0.795–0.909), remaining superior to either modality alone. DCA demonstrated greater net clinical benefit of the combined model. At the optimal cutoff, 91.5% of true pCR cases were correctly identified in the validation cohort. **Conclusions:** A radiogenomic model integrating CT radiomics and peripheral blood SNP signatures enables accurate, non-invasive prediction of pCR in LAGC/GEJC patients undergoing perioperative immunochemotherapy and may support identification of candidates for surgery-sparing management. Induction chemotherapy plus camrelizumab followed by concurrent chemoradiotherapy for unresectable locally advanced esophageal squamous cell carcinoma (ImpactCRT): Long-term outcomes of a single-arm phase II trial. First Author: Fang Peng, Department of Radiation Oncology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Concurrent chemoradiotherapy (CCRT) is the standard treatment for unresectable locally advanced esophageal squamous cell carcinoma (ESCC), with 3-year overall survival (OS) approximately 30%. Induction chemoimmunotherapy followed by CCRT appears promising, but long-term efficacy remains unclear. In the ImpactCRT study, induction chemotherapy plus camrelizumab followed by CCRT has shown promising efficacy in patients with unresectable locally advanced ESCC. Here, we reports long-term outcomes with ≥3-year follow-up. **Methods:** ImpactCRT was a prospective, single-arm, phase II study at the First Affiliated Hospital of Sun Yat-sen University. Eligible patients were aged 18–75 years with untreated, unresectable locally advanced ESCC (cT1–4bN0–3M0 or M1 limited to supraclavicular nodes). Patients received two 21-day cycles of induction therapy with albumin-bound paclitaxel (260 mg/m²), carboplatin (AUC 5), and camrelizumab (200 mg) on day 1, followed by two 28-day cycles of fluorouracil (750 mg/m² per 24 h for 5 days) and cisplatin (75 mg/m² on day 1) administered concurrently with radiotherapy (50–63 Gy in 25–28 fractions). The primary endpoint was the 1-year OS rate in the per-protocol set (PPS). The trial was registered with ChiCTR (ChiCTR2000034304). **Results:** Between July 12, 2020, and October 14, 2022, 49 patients were enrolled; all completed induction chemoimmunotherapy, and 46 received CCRT and comprised the PPS. As of January 1, 2026, median follow-up among surviving patients was 53.7 months (range 41.1–65.5). In the PPS, the 1-, 2-, 3-, and 4-year OS rates were 87.0% (95% CI 77.7–97.3), 73.9% (95% CI 62.3–87.8), 65.2% (95% CI 52.8–80.5), and 60.9% (95% CI 48.3–76.7), respectively. Corresponding PFS rates were 71.7% (95% CI 59.8–86.0), 63.0% (95% CI 50.5–78.7), 56.5% (95% CI 43.9–72.8), and 50.0% (95% CI 37.5–66.8). Median OS was not reached (95% CI 40.7 months–not reached), and median PFS was 45.5 months (95% CI 26.7–not reached). Disease progression occurred in 17 patients (37.0%), all within 3 years after treatment (median 6.1 months; range 2.9–35.2): locoregional failure in 7 (15.2%), distant metastasis in 5 (10.9%), and simultaneous locoregional and distant failure in 5 (10.9%). During follow-up, 20 patients (43.5%) died, including 12 (26.1%) due to disease progression. Grade 3 late toxicities occurred in three patients, all esophageal strictures; no grade ≥3 late toxicities were observed in the lung, heart, or other organs. **Conclusions:** Induction chemotherapy plus camrelizumab followed by CCRT showed improved long-term survival and acceptable late toxicity in unresectable locally advanced ESCC. Median PFS exceeded three years and appeared superior to previous reports. This regimen warrants further evaluation in randomized controlled trials. Clinical trial information: ChiCTR2000034304. Research Sponsor: None.

Impact of molecular profile on switch maintenance to paclitaxel plus ramucirumab (PTX-RAM) versus continuation of first-line fluoropyrimidine and oxaliplatin (FOX) chemotherapy (ChT) in patients (pts) with advanced HER2-negative gastric or gastroesophageal junction (G/GEJ) cancer: An exploratory endpoint of the ARMANI phase 3 randomized trial. First Author: Paolo Manca, Medical Oncology Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: The ARMANI trial proved the superiority of PTX-RAM switch maintenance over continuation of FOX first-line ChT in patients with advanced HER2-negative G/GEJ cancer. Here, we present the prognostic and predictive impact of baseline gene alterations. **Methods:** ARMANI was an Italian, multicenter, open-label, randomized phase 3 trial in which patients with HER2-negative G/GEJ cancer who achieved disease control after 3 months of induction FOX chemotherapy were randomized to either PTX-RAM switch maintenance or continuation of FOX. Pre-induction chemotherapy samples were sequenced by means of FoundationOne CDx, a panel comprising 324 cancer-related genes. Variants of unknown significance were filtered out. Presence of at least one pathogenic alteration was used to classify samples as altered or wild-type for the respective pathway (Cell cycle, PI3K, RAS, RTK, TGFβ, TP53 and WNT). Homologous repair deficiency (HRD) positivity was defined as the presence of a positive HRD signature (HRDsig+) as defined by FoundationOne CDx. **Results:** Sequencing data was available for 130 patients, with 65 patients treated in each arm, and 103 were evaluable for HRDsig. The most frequently altered pathways were TP53 (69.2%), Cell cycle (43.1%), PI3K (24.6%), RTK (24.6%) and RAS (23.1%). Presence of at least one alteration in the WNT pathway was observed for 22/130 patients (16.9%) and was associated with significantly higher rate of objective response to maintenance regimen (55.6% vs 17.3%, p = 0.002), longer mPFS (8.8 vs 6.0 months; HR = 0.54, 95%CI: 0.33-0.89; p = 0.017) and longer mOS (18.1 vs 14.1 months; HR = 0.53, 95%CI: 0.31-0.91, p = 0.021). TP53 pathway status was predictive for OS as switching maintenance to PTX+RAM improved OS in patients without TP53 pathway alterations (mOS 16.8 vs 8.8 months; HR 0.40, 95% CI 0.20–0.78) but not in those with at least one TP53 pathway alteration (mOS 14.7 vs 17.4 months; HR 0.94, 95% CI 0.60–1.48) (p for treatment interaction = 0.044). Ten out of 103 (9.7%) were HRDsig+. HRDsig+ status was not associated with neither PFS nor OS advantage (p = 0.676 and p = 0.623) and was not predictive of better outcomes in the FOX arm (p for treatment interaction for PFS = 0.919 and p for treatment interaction for OS = 0.558). **Conclusions:** Alterations in the WNT pathway have a positive prognostic significance in patients with G/GEJ cancer who achieved disease control after 3 months of FOX. TP53 pathway alterations bear potential for guiding the choice of PTX+RAM switch maintenance. HRDsig+ is not predictive of sensitivity of FOX in this setting. Clinical trial information: NCT02934464. Research Sponsor: None.

4061 **Poster Session**

Comparison of CLDN18/CLDN18.2 IHC assays (43-14A vs EPR19202) and the correlation with clinical efficacy in patients with gastric/gastroesophageal junction adenocarcinoma treated by the novel antibody-drug conjugate XNW27011. First Author: Jinming Yu, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China

Background: Claudin 18.2 (CLDN18.2), the dominant isoform of CLDN18 in gastric tissues, is a highly specific tight junction protein of the gastric mucosa with considerably retained expressions in gastric and gastroesophageal junction (G/GEJ) adenocarcinoma, making it a clinically actionable therapeutic target. Accurate immunohistochemical (IHC) assessment of CLDN18.2 expression is critical for patient selection in CLDN18.2-targeted therapies. Here, we report the findings of the analytical comparability, concordance and clinical efficacy outcomes between two CLDN18/CLDN18.2 antibodies (VENTANA CLDN18 [43-14A] and Abcam CLDN18.2 [EPR19202]), from a Phase I/II study of a novel antibody-drug conjugate XNW27011 (NCT06792435). **Methods:** This retrospective study utilized formalin-fixed paraffin-embedded (FFPE) samples of 121 patients with G/GEJ adenocarcinoma enrolled in the Phase I/II study of XNW27011. Each sample was stained with CLDN18 (43-14A) and CLDN18.2-specific (EPR19202) antibodies. Efficacy in objective response rate (ORR) was evaluated across CLDN18/CLDN18.2 expression strata defined by each assay antibody in patients treated with XNW27011 at doses of 2.4–6.0 mg/kg administered intravenously every 3 weeks. Concordance between the two assay antibodies was assessed by the percentage of the overall agreement (positive or negative) primarily at the cutoff of ≥20% tumor cells with 2+ to 3+ membranous staining. **Results:** Therapeutic efficacy outcomes of XNW27011 in ORR were highly consistent across expression strata defined by either 43-14A or EPR19202 assay antibody. In patients with CLDN18/CLDN18.2 expression defined as IHC ≥2+ in ≥20% of tumor cells, ORRs were 45.5% and 45.3% using EPR19202 and 43-14A assay antibody, respectively. EPR19202 and 43-14A IHC assays demonstrated high concordance, with an overall agreement of 90.1%. **Conclusions:** The IHC assays of CLDN18.2 expression with EPR19202 or CLDN18 expression with 43-14A demonstrate comparable analytical performance with high concordance. The alignment of efficacy outcomes across the two antibody-defined strata supports that CLDN18 and CLDN18.2-specific antibodies can identify patient populations with similar clinical benefit. Both antibodies can support the clinical development of XNW27011 in the treatment of patients with G/GEJ adenocarcinoma. Research Sponsor: None.

4062 **Poster Session**

Phase II study of ceralasertib (ATR inhibitor) plus durvalumab in patients with advanced gastric cancer (AGC) who progressed on prior anti-PD-(L)1 therapy. First Author: Sung Hee Lim, Division of Hematology-Oncology, Department of Medicine, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, South Korea

Background: The standard first-line therapy for advanced gastric cancer (AGC) now includes immune checkpoint inhibitors (ICIs), but resistance is inevitable. ATR inhibition may sensitize tumors to ICIs by enhancing DNA damage and activating the cGAS-STING pathway. We evaluated the efficacy and immunologic impact of ceralasertib (ATRi) plus durvalumab in IO-pretreated AGC. **Methods:** This open-label phase II trial (NCT03780608) enrolled patients with metastatic gastric adenocarcinoma who progressed on prior anti-PD-(L)1 therapy. Patients received ceralasertib (240mg BID, Days 1–7) and durvalumab (1500mg IV, Day 8) every 28 days. The primary endpoint was ORR (RECIST v1.1). Serial endoscopic biopsies were collected at baseline (BL), post-ATRi monotherapy (FU1), and post-durvalumab combination (FU2) for multi-omics analysis (WES/WTS/scRNA-seq). **Results:** Thirty patients were enrolled (median 4 prior lines; all HER2-negative). ORR was 33.3% (10/30) and DCR was 56.7%. Median PFS was 4.3 months (95% CI, 1.45–7.10); median OS was not reached. Patients receiving study treatment immediately after prior IO failure had significantly longer PFS than those with intervening non-IO lines ($p < 0.05$). Grade 3 TRAEs occurred in 10% (3/30) of patients, with no new safety signals identified. Dose reductions of ceralasertib occurred in 4 patients. Multi-omics revealed that higher baseline scarHRD scores correlated with shorter PFS (p = 0.031). scRNA-seq showed that responders (R) had significant depletion of aneuploid clones post-treatment, whereas non-responders (NR) exhibited clonal persistence. Mechanistically, R showed baseline enrichment of the ATR-ATRIP axis, indicating functional dependency on replication stress tolerance. ATR inhibition in R induced replication fork collapse and ATM-CHEK2-mediated apoptosis. Conversely, NR displayed base excision repair deficiency signatures and adaptive G1-phase retention, facilitating evasion of ATRi-induced lethality. **Conclusions:** Ceralasertib plus durvalumab is efficacious and well-tolerated in IO-refractory AGC. The higher efficacy observed in patients treated immediately after prior IO failure suggests that ATR inhibition may effectively reverse acquired resistance to PD-1 blockade. This biomarker-driven approach warrants further validation in a larger cohort. Clinical trial information: NCT03780608. Research Sponsor: None.

Biomarker-driven assessment of immunochemotherapy with or without fruquintinib as first-line treatment for advanced gastric/GEJ adenocarcinoma: Initial clinical results and subgroup analysis from the MGC-FLORA study. First Author: Xiaodong Zhu, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: The MGC-FLORA study is a prospective biomarker-exploratory trial primarily designed to identify predictive biomarkers (including gut microbiota and blood-based biomarkers) for first-line immunochemotherapy in advanced gastric/gastroesophageal junction (G/GEJ) adenocarcinoma. A key exploratory question is whether adding anti-angiogenic therapy (fruquintinib) modifies the efficacy landscape and its associated biomarkers. This interim analysis compares clinical outcomes between chemotherapy plus immunotherapy (CHEM cohorts) and chemotherapy plus immunotherapy plus fruquintinib (FRUQ cohorts). The FRUQ cohort is concurrently registered as an independent phase II clinical study (NCT06158919). **Methods:** This analysis included patients enrolled before September 30, 2025, with follow-up until January 15, 2026. Patients with previously untreated, unresectable locally advanced or metastatic G/GEJ adenocarcinoma were enrolled into two cohorts in this non-randomized study: CHEM (PD-1 inhibitor plus XELOX/SOX) and FRUQ (PD-1 inhibitor plus XELOX/SOX plus fruquintinib 4mg QD, days 1-14). After 6 induction cycles, oxaliplatin was discontinued in both cohorts, and maintenance therapy consisted of S-1/capecitabine plus PD-1 inhibitor, with or without continued fruquintinib. Blood and stool samples were collected at baseline (C1D1), after two treatment cycles, and at progression for future biomarker analysis (gut microbiota, cfDNA/cfRNA); the present report focuses on clinical outcomes. **Results:** A total of 126 patients were included (CHEM: n = 83; FRUQ: n = 43), with a median follow-up of 10.97 months. In the overall population, median PFS was 8.38 months and median OS was 18.53 months. Among evaluable patients, ORR was 47.1% (16/34) in the CHEM cohort versus 76.7% (33/43) in the FRUQ cohort, indicating a higher response rate with the addition of fruquintinib. Median PFS was 8.38 months for CHEM and 10.35 months for FRUQ (HR = 0.63, 95% CI 0.37-1.08; p = 0.09). After propensity score matching for sex, age, liver metastasis status, number of target lesions, and Claudin18.2 expression (n = 29 per cohort), the PFS benefit associated with fruquintinib became more pronounced (HR = 0.45, 95% CI 0.20-1.02; p = 0.05). **Conclusions:** This initial analysis from the biomarker-oriented MGC-FLORA study suggests that the addition of fruquintinib to first-line immunochemotherapy may improve clinical efficacy in advanced G/GEJ adenocarcinoma. Consistent trends toward prolonged PFS were observed in both the overall and propensity score–matched populations, supporting a potential therapeutic benefit of fruquintinib. These findings warrant further validation in randomized trials and integrated biomarker analyses. Research Sponsor: None.

Toripalimab plus chemotherapy and radiotherapy for treatment-naïve advanced esophageal squamous cell carcinoma: Long-term survival and recurrence patterns. First Author: Lei Wu, Radiation Oncology Key Laboratory of Sichuan Province, Sichuan Clinical Research Center for Cancer, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, University of Electronic Science and Technology of China, Chengdu, China

Background: Concurrent chemoradiotherapy plus PD-1 blockade is standard for locally advanced esophageal squamous cell carcinoma (ESCC), but its role in advanced disease remains undefined. We investigated the safety and efficacy of Toripalimab combined with chemotherapy and radiotherapy (RCIT) as first-line treatment for advanced ESCC, analyzing long-term survival, recurrence patterns, and immune biomarkers. **Methods:** This single-arm, phase II trial enrolled treatment-naïve patients with stage IV ESCC (N3 nodal or oligometastases; 5 lesions in 3 organs). Treatment comprised induction chemoimmunotherapy (2 cycles) followed by concurrent radiotherapy (Cycles 3-4) and maintenance immunotherapy. Patients received Paclitaxel (135-175 mg/m2) and Carboplatin (AUC 4-6) plus Toripalimab (240 mg) on day 1 (Q3W). Intensity-modulated radiotherapy (50-50.4 Gy/25-28f) targeted primary/regional lesions, while SBRT (30-40 Gy/3-5f) targeted oligometastases. The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), recurrence patterns, health-related quality of life (HRQOL), and biomarker analysis via multiplex immunofluorescence (mIF). **Results:** Thirty-three patients were enrolled. At a median follow-up of 33.4 months, the 2-year PFS and OS rates were 30.3% (95% CI: 18.1-50.8) and 48.5% (95% CI: 34.1-68.9), respectively. In the efficacy-evaluable population completing radiotherapy (n = 26), outcomes were significantly superior to those who did not, with a median OS of 27.4 months and a 2-year OS of 61.5% (HR = 0.26, p = 0.004). Recurrence occurred in 26 (78.8%) patients, comprising locoregional only (27.3%), distant only (18.2%), and combined failure (33.3%). Notably, among patients completing RT, in-field recurrence (57.7%) remained a predominant failure pattern despite multimodal therapy. HRQOL analysis demonstrated significant post-induction improvement in pain and social functioning scores, whereas radiotherapy transiently worsened dysphagia at 3 months post-RT (p = 0.041). Translational analysis revealed that high baseline tumor infiltration of CD8+ T cells, PD-L1+ dendritic cells, and PD-L1+ macrophages, alongside elevated serum IL-4, IL-17, and IFN-γ\gamma, were significantly associated with long-term survival (OS $\geq$24 months; $p < 0.05$). **Conclusions:** First-line RCIT yields promising long-term survival in advanced oligometastatic ESCC, particularly in patients completing the full radiotherapeutic course, achieving a 2-year OS of 61.5%. However, high rates of in-field recurrence suggest a need for further optimization of local control strategies. Baseline immune infiltrates and cytokine profiles offer potential predictive value for patient stratification. Randomized trials are warranted to validate these findings. Clinical trial information: ChiCTR2100046715. Research Sponsor: This work was supported by the NSFC program (82573448).

Disitamab vedotin (RC48), tislelizumab, and S-1 as first-line therapy for HER2-overexpressing advanced gastric or gastroesophageal junction adenocarcinoma (GC/GEJC): Updated survival and exploratory biomarker results from the RCTS trial. First Author: Lian Liu, Qilu Hospital of Shandong University, Jinan, China

Background: Anti-PD1 antibody has significantly improved survival in patients with HER2-overexpressing and PD-L1 combined positive score (CPS) $\geq$1 GC/GEJC when added to trastuzumab and chemotherapy. Recent trials revealed that HER2-targeted antibody-drug conjugates combined with anti-PD1 antibody, have also shown promising efficacy in this population. We report updated survival, safety, and exploratory biomarker results of RC48 combined with tislelizumab and the oral fluoropyrimidine S-1 as first-line therapy for patients with HER2-overexpressing GC/GEJC. **Methods:** This single-arm, multicenter clinical trial enrolled patients with unresectable or metastatic HER2-overexpressing (IHC 3+ or 2+, regardless of FISH status) GC/GEJC. Patients received RC48 (2.5 mg/kg), tislelizumab (200 mg), and S-1 (40–60 mg BID for 14 days) every 3 weeks until disease progression or intolerable toxicity. The primary endpoint was objective response rate (ORR). Secondary endpoints were progression-free survival (PFS), overall survival (OS) and safety. Exploratory analyses included dynamic peripheral T-cell receptor (TCR) sequencing and longitudinal circulating tumor DNA/cell-free DNA (cfDNA) profiling. **Results:** 57 patients were enrolled, 71.9% HER2 IHC 3+, 17.5% IHC 2+/FISH+, and 10.5% IHC 2+/FISH-; 45.6% had CPS $\geq$1. Until Dec 31, 2025, the median follow-up was 28.2 months. In the ITT population, the confirmed ORR was 89.5% (95% CI: 78.5–96.0%), including 8.8% complete responses; disease control rate was 98.2%. Median PFS was 13.8 months (95% CI: 10.3–24.0), and median OS was 31.9 months (95% CI: 22.1–not reached). In the CPS $\geq$1 and CPS $<$ 1 subgroups, ORRs were 92.3% (95% CI: 74.9–99.1%) and 87.1% (95% CI: 70.2–96.4%), with median PFS 16.7 vs 10.0 months and median OS 31.9 vs 25.4 months, respectively. Grade $\geq$3 treatment-related adverse events occurred in 64.9%, mainly decreased white blood cell count (29.8%), decreased neutrophil count (12.3%), anemia (10.5%), and peripheral motor neuropathy (10.5%). In patients with paired TCR samples, higher treatment-induced clonal expansion score was associated with improved PFS (HR 0.34; P = 0.017) and OS (HR 0.33; P = 0.037), with particularly prognostic discrimination in the CPS $<$ 1 subgroup. In patients with longitudinal cfDNA, cfDNA tumor fraction increases preceded imaging-defined progression in most patients who progressed. **Conclusions:** The combination of RC48, tislelizumab and S-1 as a first-line therapy shows encouraging response rates and updated survival with manageable safety in HER2-overexpressing GC/GEJC, including patients with CPS $<$ 1. TCR clonal expansion may serve as a robust biomarker of antitumor immune activation, independent of PD-L1 expression levels. Clinical trial information: NCT05586061. Research Sponsor: None.

Efficacy of nimotuzumab combined with concurrent chemoradiotherapy for patients with postoperative loco-regional recurrent esophageal squamous cell carcinoma: A phase II study. First Author: Jialiang Zhou, Affiliated Hospital of Jiangnan University, Wuxi, China

Background: The clinical therapeutic effect for patients with postoperative loco-regional recurrent esophageal squamous cell carcinoma (ESCC) is not satisfactory. Nimotuzumab, an EGFR-targeted humanized antibody, showed efficacy in the treatment of ESCC. We explored the efficacy of nimotuzumab combined with concurrent chemoradiotherapy (CCRT) for patients with postoperative loco-regional recurrent ESCC. **Methods:** Eligible patients (18-75 years) with postoperative loco-regional recurrent ESCC were enrolled in this single-arm phase II study, received nimotuzumab (400mg on D1, 200mg/w for 6 weeks) combined with CCRT (chemotherapy:TP regimen, radiotherapy: 45-50.4Gy/25-28f/5-6w), sequentially nimotuzumab 200mg every 3 weeks plus chemotherapy (patients with partial response or stable disease). The primary endpoint was objective response rate (ORR), the second endpoints were disease control rate (DCR), overall survival (OS), progression-free survival (PFS), and local-regional control (LRC) and adverse events. **Results:** From Sep 2021 to Apr 2024, 44 patients were screened, ultimately 42 patients were included in the Full Analysis set. The median age was 69 years (range: 48-75). 12 (28.57%) patients achieved complete response, 24 (57.14%) patients with partial response, 5 (11.90%) patients with stable disease, and 1 (2.38%) patient with progressive disease. ORR was 85.71%, and DCR was 97.62%. The failure patterns showed that 10 (23.81%) patients had loco-regional recurrence, and 9 (21.43%) had distant metastases after CCRT. The median follow-up was 29.3 months (95%CI: 25.7-38.0). 3-year OS was 51.8% (95%CI: 36.9-72.8%), with the median OS was not reached. 3-year PFS was 33.4% (95%CI: 20.4-54.7%), and the median PFS was 15.1 months (95%CI: 11.8-NE), 3-year LRC was 46.1% (95%CI: 29.9-71.0%), the median LRC was 30.8 (95%CI: 16.6-NE). The most common Graded 3-5 adverse events (AEs) included leukopenia, thrombocytopenia, hemoglobin decreased, radiation esophagitis, radiation-induced lung injury, fatigue, and radiodermatitis. 4 patients experienced Grade 3-5 radiation esophagitis, in which 2 patients developed esophageal fistulas (1 patient died). No nimotuzumab-related serious AEs occurred. **Conclusions:** Nimotuzumab combined with CCRT showed promising ORR and survival with tolerable toxicity in patients with postoperative loco-regional recurrent ESCC. Clinical trial information: ChiCTR2200063875. Research Sponsor: None.

Survival outcome of sandwich therapy with induction chemo-immunotherapy followed by concurrent chemoradiotherapy and sequential immune maintenance therapy in locally advanced unresectable esophageal squamous cell carcinoma (ESCC) patients: A multi-center prospective study. First Author: Zhichao Fu, 900 Hospital of the Joint Logistics Support Force, Fuzhou, China

Background: PD-1 inhibitor, combined with chemotherapy, is recommended in first-line treatment for metastatic ESCC, but its role remains undefined in locally advanced ESCC. This trial aimed to investigate the survival outcome and safety of the 'Sandwich Therapy' consisting of induction chemoimmunotherapy followed by definitive chemoradiotherapy (dCRT) and sequential immune maintenance therapy. **Methods:** This is a multicenter, prospective study. Patients with histologically confirmed, clinical stage I–IVA and unresectable esophageal squamous cell carcinoma (ESCC) were included. Patients received 1-8 cycles of chemoimmunotherapy (intravenous paclitaxel (175 mg/m^2) plus platinum-based chemotherapy), then concurrent chemoradiotherapy followed by tislelizumab (200mg intravenously, every 3 weeks) until disease progression or the end of the study. The primary outcome was progression-free survival (PFS). The secondary outcomes included overall survival (OS) and the incidence of adverse events (AE). **Results:** Between August 2022 and Aug 2025, 77 patients were enrolled and all proceeded to the immune maintenance therapy phase. The median age was 61 years (IQR 55-69), and 78% had clinical stage III or IV disease. With median follow-up of 19 months (95CI), median PFS was 17.0 months (95% CI:12.0–36.0) , with 1-, 2- and 3-year PFS rate of 56.4%, 39.9% and 25.6%, respectively. The median OS was 45.0 months (95%CI:20.1-69.3), with 1-, 2- and 3-year OS rate of 74.9%, 63.2% and 50%, respectively. The objective response rate (ORR) was 55.8%, and the disease control rate was 92.2%. Grade ≥3 AE occurred in 27 (35.1%) patients during the treatment. The most common grade ≥3 AE was lymphopenia, which was reported in 22 (28.6%) patients. **Conclusions:** For locally advanced ESCC, induction chemoimmunotherapy followed by dCRT and subsequent maintenance of immunotherapy may improve PFS and OS with a manageable safety profile. Clinical trial information: NCT05515315. Research Sponsor: None.

4069 Poster Session

Incidence and prognostic impact of recurrence in esophageal carcinoma patients achieving complete pathological response after neoadjuvant chemoradiotherapy or perioperative chemotherapy. First Author: Sibgha Aimon, Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore, Pakistan

Background: Esophageal carcinoma remains a global challenge, ranking 7th in cancer-related mortality. While the CROSS trial established neoadjuvant chemoradiotherapy (nCRT) as a standard of care with a 29% pathological complete response (pCR) rate, real-world data in diverse histological populations—particularly Squamous Cell Carcinoma (SCC)—are evolving. We aimed to evaluate the impact of pCR on Overall Survival (OS) and Disease-Free Survival (DFS) in a high-volume surgical cohort. **Methods:** A retrospective analysis of a prospective database was conducted for patients undergoing curative-intent esophagectomy at a tertiary cancer center (2019–2023). Inclusion: Patients receiving neoadjuvant therapy (nCRT or perioperative chemotherapy). Exclusion: Patients with upfront surgery, palliative resections, or incomplete records. Survival outcomes were analyzed using Kaplan-Meier curve. **Results:** Of 546 patients, 51% were male with a mean age of 44 ± 9 years. nCRT was the primary neoadjuvant modality (92.3%), followed by perioperative chemotherapy (7.7%). pCR was achieved in 54.8% of patients. At a median follow-up of 5 years, the overall recurrence rate was 27.1%; notably, only 28.3% of the pCR group experienced recurrence compared to the non-pCR group ($p < 0.001$). Recurrence patterns distant (48.6%), followed by locoregional (44.6%), and both (6.8%). The pCR group demonstrated superior survival outcomes: Mean OS: 57 ± 0.7 months vs 52 ± 1 months in non-pCR (p = 0.001); Mean DFS: 52 ± 1 months vs 35 ± 1 months in non-pCR ($p < 0.001$). Total study mortality was 8.4%. **Conclusions:** In this large South Asian cohort, pCR was achieved in over half of the patients following neoadjuvant therapy and served as a robust predictor of both OS and DFS. These findings reinforce pCR as a critical surrogate endpoint for long-term oncological success and suggest that tumor biology in this region may be particularly sensitive to multimodality protocols. Research Sponsor: None.

Efficacy of durvalumab and safety by treatment period in MATTERHORN: A randomized, phase 3 study of durvalumab plus 5-fluorouracil, leucovorin, oxaliplatin, and docetaxel (FLOT) chemotherapy in resectable gastric/gastroesophageal junction (G/GEJ) cancer. First Author: Zev A. Wainberg, Department of Gastrointestinal Medical Oncology, David Geffen School of Medicine at UCLA, Los Angeles, CA

Background: In MATTERHORN (NCT04592913), perioperative durvalumab (D) + FLOT significantly improved event-free survival (EFS) and overall survival vs placebo (Pbo) + FLOT in participants (pts) with resectable G / GEJ cancer. Here, we report EFS by treatment period completion status. **Methods:** In this global, double-blind, Phase 3 study, pts with histologically confirmed, resectable, untreated G / GEJ adenocarcinoma were randomized 1:1 to D 1500 mg or Pbo every 4 weeks (Q4W) on Day 1 + FLOT every 2 weeks on Days 1 and 15 for 4 cycles (2 cycles each neoadjuvant and adjuvant [adjuvant: 4–12 weeks post-surgery]), followed by D 1500 mg or Pbo Q4W for 10 additional cycles (adjuvant monotherapy). EFS (time from randomization to progression, local or distant recurrence, or death) was assessed by treatment period completion status (Table). Safety was also assessed. Landmark EFS rates were calculated by the Kaplan–Meier method. Hazard ratios and their confidence intervals were estimated by the Cox proportional hazards model. **Results:** The number of pts who received treatment in each period was similar in the D + FLOT and Pbo + FLOT treatment arms (Table). EFS landmark rates at 12 and 24 months were highest in pts who completed all adjuvant D / Pbo in both arms; EFS was improved in the D + FLOT vs Pbo + FLOT arm irrespective of treatment periods started / completed (Table). A smaller proportion of Grade 3–4 adverse events (AEs) and serious AEs (SAEs) were reported in the adjuvant monotherapy period with D + FLOT and Pbo + FLOT (Grade 3–4: 21.2% and 20.5%; SAEs: 14.5% and 14.5%, respectively) when compared with the overall treatment period (Grade 3–4: 71.6% and 71.2%; SAEs: 48.2% and 44.1%, respectively). In the adjuvant monotherapy period, the rate of any AEs leading to discontinuation of D / Pbo was 5.8% in the D + FLOT vs 2.7% in the Pbo + FLOT arm. **Conclusions:** EFS landmark rates were greatest for pts who completed the full adjuvant regimen compared with those who discontinued prematurely in both arms. Moreover, the addition of D to FLOT improved EFS regardless of treatment periods started / completed. Safety was manageable and tolerable in the adjuvant monotherapy period. Clinical trial information: NCT04592913. Research Sponsor: AstraZeneca.

Non-invasive strategy for gastric cancer detection: Integration of cell-free DNA fragmentomics and protein biomarkers. First Author: Lian Lian, Department of Oncology, Suzhou Xiangcheng People's Hospital, Suzhou, China

Background: Gastric cancer (GC) ranks the fifth most common cancer worldwide. Although gastroscopy is widely acknowledged as the gold standard for GC detection, its invasiveness limits its utility in large-scale screening. Accurate, non-invasive diagnostic modalities are urgently needed. Cell-free DNA (cfDNA) fragmentomics has emerged as a promising tool for cancer detection. This study aimed to develop and validate a novel non-invasive model for GC detection based on cfDNA fragmentomics and protein biomarkers. **Methods:** A total of 257 participants, comprising 120 GC patients and 137 non-cancer individuals, were enrolled and divided into a training cohort (n = 129) and a test cohort (n = 128). Low-coverage whole-genome sequencing was performed on plasma cfDNA. We evaluated eight multi-dimensional cfDNA fragmentomics features individually, and selected four, including fragment size ratio, copy number variation, 9-bp end motif, and fragment size at transcription starting sites, to build an ensemble model (GaFraD) to detect GC. Furthermore, conventional protein biomarkers of GC were assessed and integrated with GaFraD model to generate a CONFIRM model aimed at improving diagnostic performance. **Results:** The GaFraD model achieved an area under the receiver-operating characteristic curve (AUC) of 0.953 (95% CI: 0.918 – 0.979) in the training cohort and 0.970 (95% CI: 0.944 – 0.990) in the test cohort, with a sensitivity of 95.0% and a specificity of 80.9%. By incorporating protein biomarkers CA19-9 and PG-I/PG-II, the CONFIRM model further reached an AUC of 0.967 (95% CI: 0.929 – 0.992) in the training cohort and 0.986 (95% CI: 0.966 – 1.000) in the test cohort, attaining a sensitivity of 95.0% and specificity of 95.6%. Moreover, the CONFIRM model also exhibited remarkable performance in discriminating early-stage GC patients from controls (AUC = 0.983, sensitivity: 95.6%, specificity: 94.2%). **Conclusions:** Our model exhibits high discriminatory power in distinguishing GC patients from controls, highlighting the strong clinical potential of combining cfDNA fragmentomics with protein biomarkers for non-invasive, early GC detection. This approach offers a promising pathway towards earlier, accurate, and non-invasive clinical diagnosis of GC. Prevalence of *CDH1* germline variants in gastric cancer patients with exome-inferred ancestry. First Author: Skylar Nahi, UT Southwestern Medical Center, Dallas, TX

Background: Germline pathogenic or likely pathogenic (P/LP) *CDH1* variants increase the lifetime risk of developing diffuse gastric cancer (DGC). Given that the epidemiology and prognosis of gastric cancer vary based on patient ancestry, and Hispanic and Black/African-American patients have been underrepresented in clinical and translational research, we sought to determine the prevalence of *CDH1* variants in a diverse population of gastric cancer patients. **Methods:** Germline whole exome sequencing (WES) data from gastric cancer patients were obtained as part of commercial ordering of personalized circulating tumor DNA testing (Signatera, Natera, Inc.) from March 2024 to June 2025. Ancestry was inferred by EthSeq and classified into predefined groups: European (EUR), admixed American (AMR), African (AFR), and East Asian (EAS). Germline single-nucleotide variants and short insertions/deletions were identified and annotated with Variant Effect Predictor (v.105), and the pathogenicity of variants in *CDH1* was determined using classifications available in the ClinVar database. The prevalence of P/LP variants and variants of uncertain significance (VUS) were compared across ancestries. Potential pathogenicity of VUS was evaluated using *in silico* predictors SIFT (v5.2.2), Polyphen (v2.2.2), and AlphaMissense (hg19). **Results:** Among 2,567 patients, 55% (1,414/2,567) were male and the median age was 67 years. Ancestry inference identified 47% (n=1,201) as EUR, 22% (n=575) as AMR, 18% (n=457) as AFR, and 13% (n=334) as EAS. Patients with AMR ancestry were younger compared to EUR ancestry patients (median 62 years vs 69 years; adj $p<0.0001$), and less likely to be male (51% [295/575] vs. 58% [693/1201]; OR, 0.7; 95% CI, 0.63–0.94; p=0.015). No significant differences in age or sex were observed in patients with AFR (median 68 years, 55% male) or EAS (median 68 years, 52% male) ancestry compared to EUR. Overall, 0.7% (n=17) gastric cancer patients had a P/LP variant, and there was no difference across ancestries (0.8% of EUR, 0.5% of AMR, 0.4% of AFR, and 0.6% of EAS patients). We found that 1.1% (n=27) of the cohort had a *CDH1* VUS, the rate for which did not vary across ancestries (1.2% of EUR, 0.52% of AMR, 0.84% of AFR, 0.60 of EAS). Of the 21 unique VUS, 33% (n=7) were each predicted to be pathogenic by all three *in silico* predictors. One unique VUS was observed in two unrelated patients: NM_004360.5:c.635G>T (p.Gly212Val). The predicted-pathogenic VUS were similarly distributed across ancestries. **Conclusions:** This real-world analysis highlights that *CDH1* VUS were similarly distributed across ancestries. Notably, we found that one-third of VUS identified were predicted to have pathogenic function across three *in silico* prediction tools. This highlights the need for functional assays to determine the variant biology to improve gastric cancer risk assessment. Research Sponsor: None.

Neoadjuvant and adjuvant pembrolizumab plus chemotherapy for locally advanced gastric or gastroesophageal junction adenocarcinoma: Outcomes from the microsatellite instability-high population of the phase 3 KEYNOTE-585 study. First Author: Sun Young Rha, Department of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: In the randomized phase 3 KEYNOTE-585 study (NCT03221426), perioperative pembrolizumab (pembro) plus chemotherapy (chemo) significantly improved pathologic complete response (pCR) vs placebo (pbo) plus chemo (diff, 10.9%; 95% CI, 7.5-14.8; $P < 0.00001$), with no new safety signals in participants (pts) with locally advanced gastric or gastroesophageal junction (G/GEJ) adenocarcinoma. We present outcomes for the microsatellite instability-high (MSI-H) population. **Methods:** Eligible pts had untreated resectable locally advanced G/GEJ adenocarcinoma (including Siewert type 2 or 3 tumors); MSI was centrally assessed. Pts enrolled in the main cohort (n = 804) received neoadjuvant pembro 200 mg intravenously (IV) every 3 weeks (Q3W) or pbo plus chemo (cisplatin + capecitabine or 5-FU) for 3 cycles; after surgery, pts received adjuvant pembro or pbo plus chemo Q3W for 3 cycles, then adjuvant pembro or pbo Q3W for 11 cycles. Pts in the fluorouracil, docetaxel, and oxaliplatin (FLOT) cohort (n = 203) received neoadjuvant pembro 200 mg IV Q3W or pbo Q3W for 3 cycles plus FLOT Q2W for 4 cycles; after surgery, pts received adjuvant pembro or pbo Q3W for 3 cycles plus FLOT Q2W for 4 cycles, then adjuvant pembro or pbo Q3W for 11 cycles. End points were pCR (blinded independent central review [BICR]), event-free survival (EFS; RECIST v1.1 by BICR), overall survival (OS), and safety. We report outcomes in the main and FLOT cohorts combined. The data cutoff date was February 16, 2024 (final analysis). **Results:** Data from the 81 pts with MSI-H status were analyzed (n = 43, pembro + chemo; n = 38, pbo + chemo). The pCR rate was 39.5% (95% CI, 25.0-55.6) in the pembro group and 0% (95% CI, 0.0-9.3) in the pbo group (diff, 39.5%; 95% CI, 26.3-54.5). The median EFS was not reached (NR; 95% CI, 49.9-NR) and 60.1 months (95% CI, 18.6-NR), respectively (HR, 0.58; 95% CI, 0.26-1.31); 24/48-month EFS rates were 78%/73% in the pembro group and 68%/68% in the pbo group. The median OS was NR (95% CI, NR-NR) in both treatment groups (HR, 0.50; 95% CI, 0.19-1.30); 24/48-month OS rates were 91%/86% in the pembro group and 76%/74% in the pbo group. Treatment-related adverse events (AEs) occurred in all 43 pts (100%) in the pembro group and 37 (97%) in the pbo group. Grade 3-5 treatment-related AEs occurred in 32 (74%) and 25 (66%) pts, respectively. Discontinuation of any drugs due to treatment-related AEs occurred in 15 pts (35%) in the pembro group and 12 (32%) in the pbo group. No deaths due to treatment-related AEs were reported. **Conclusions:** In this post hoc analysis, efficacy outcomes for pts with MSI-H G/GEJ adenocarcinoma suggested a consistent trend with numerically more pronounced difference between the treatment groups, with a manageable safety profile. Further studies in this population are warranted. Clinical trial information: NCT03221426. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Neoadjuvant chemoradiotherapy versus neoadjuvant chemotherapy followed by D2 gastrectomy and adjuvant chemotherapy for locally advanced gastric cancer (Neo-CRAG): A randomized, multicenter, phase 3 trial. First Author: Rui-Hua Xu, Department of Medical Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangdong Provincial Clinical Research Center for Cancer, Sun Yat-sen University, Guangzhou, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

4076 **Poster Session**

A multicenter non-randomized phase III study of sentinel node navigation surgery for early gastric cancer. First Author: Yuko Kitagawa, Department of Surgery, Keio University School of Medicine, Tokyo, Japan

Background: Sentinel node navigation surgery (SNNS) has the potential to minimize the extent of gastrectomy, thereby improving quality of life (QOL) after surgery for patients with early gastric cancer (GC). This prospective, multicenter, non-randomized, phase III study aims to evaluate the long-term outcomes of SNNS for early GC. **Methods:** A total of 13 institutions enrolled clinically diagnosed primary T1N0M0 gastric cancer patients with a single lesion ($\leq$40 mm) and without previous endoscopic treatment. Sentinel nodes (SNs) were identified using dye and radioisotope tracers, then subjected to intraoperative rapid pathology. Patients with negative SN metastasis underwent individualized surgery consisting of limited stomach resection and SN basin dissection, while those with positive SN metastasis underwent standard gastrectomy with D2 lymph node dissection. The primary endpoint was five-year relapse-free survival (RFS). The secondary endpoints were overall survival (OS), SN detection rate, diagnostic accuracy for SNs, SN distribution, and the distribution of metastatic and non-SNs. Postoperative QOL was also assessed. RFS was assessed in the full analysis set (FAS), excluding patients who did not undergo intraoperative SN biopsy and pathological assessment during surgery. The data cutoff date for the analysis was May 31, 2025. Clinical trial information: jRCTs031180432. **Results:** A total of 187 patients were enrolled from May 2014 to May 2020. Of the 180 patients in FAS, 62.2% were male. The median (range) age was 64 (27–85). cT1a/cT1b was 18.3%/81.7%, respectively. The median follow-up time was 60.2 months (range: 9.0–62.8). The 5-year RFS rate (95% CI) was 95.6% (91.43–98.06). Since the lower boundary of the 95% CI exceeded the predefined threshold of 90%, the study met its primary endpoint. Events for RFS included one recurrence and three non-cancer deaths. SNs were identified in all patients, and LN metastasis was detected in 17 patients (9.4%) during surgery. Finally, 143 patients (79.4%) underwent individualized surgery consisting of limited stomach resection and SN basin dissection. The 5-year RFS rate (95% CI) for this cohort was 96.5% (92.03 - 98.86). There was no mortality after surgery. **Conclusions:** SNNS for early GC has been shown to be non-inferior to standard gastrectomy, with an acceptable toxicity profile. SNNS represents a promising alternative as a potential new standard treatment for early GC. Clinical trial information: jRCTs031180432. Research Sponsor: Japan Agency for Medical Research and Development (AMED).

FGF4-mediated resistance to combined anti-angiogenic and immunotherapy in esophageal squamous cell carcinoma via suppression of high endothelial venules and tertiary lymphoid structure formation. First Author: Weixiong Yang, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Many patients with locally advanced esophageal squamous cell carcinoma (LA-ESCC) fail to achieve a pathological complete response (pCR) following neoadjuvant immunochemotherapy plus anti-angiogenic therapy, which is associated with a poor prognosis. The identification of predictive biomarkers and the elucidation of resistance mechanisms constitute a major challenge. This study aims to identify relevant biomarkers and elucidate the underlying mechanisms to improve therapeutic outcomes. **Methods:** Exploratory analyses were conducted on 70 untreated LA-ESCC patients from a phase II clinical trial (ChiCTR2100051763) treated with two 21-day cycles of neoadjuvant treatment with intravenous camrelizumab (200mg), albumin-paclitaxel (260mg/m^2), carboplatin (AUC=5) on day 1, and oral apatinib (250mg) on days 1-14, followed by the third cycle without apatinib. Pre-treatment tumor tissues were subjected to transcriptomic and whole-exome sequencing to identify differential pathways and genetic alterations between patients achieving pCR and non-pCR. Candidate biomarkers were further validated by immunohistochemistry. In vitro and in vivo experiments were employed to elucidate the mechanisms underlying treatment resistance. **Results:** Pathway analysis identified significant enrichment of the fibroblast growth factor receptor (FGFR) signaling pathway in non-pCR patients, with FGF4 as the most upregulated factor. FGF4 alterations were primarily gene amplifications, occurring in 40% of cases. FGF4 expression predicted treatment resistance (non-pCR) with an AUC of 0.857 (95% CI: 0.744–0.97). Multiplex immunohistochemistry revealed that tumors overexpressing FGF4 exhibited impaired vascular normalization, evidenced by significantly reduced pericyte coverage and basement membrane integrity. These tumors also showed lower densities of high endothelial venules (HEVs), CD8+ T cells, and tertiary lymphoid structures (TLSs) following combination therapy. In vivo experiments confirmed that FGF4 overexpression led to decreased pericyte and basement membrane coverage, reduced HEV density, and diminished CD8+ T cell infiltration. Notably, pharmacological inhibition of FGFR signaling reduced tumor growth and increased the pCR rate, effectively reversing the resistance mediated by FGF4. **Conclusions:** Aberrant FGF4 expression drives resistance to combined immunochemotherapy and anti-angiogenic therapy by impeding vascular normalization, which subsequently suppresses the formation of HEVs and tertiary TLSs. Targeting FGFRs might be a promising strategy to overcome FGF4-driven treatment resistance in ESCC. Clinical trial information: ChiCTR2100051763. Non-operative management in mismatch repair deficient (dMMR) esophagogastric cancer (EGC) following immune checkpoint inhibition (ICI). First Author: Charlton Tsai, Memorial Sloan Kettering Cancer Center, New York City, NY

Background: ICI achieves deep and durable responses in patients with dMMR and microsatellite instability-high (MSI-H) EGC, creating an opportunity for non-operative management (NOM) of localized disease. However, limited data exists regarding long-term outcomes with NOM and factors associated with ICI failure, which we evaluated in this retrospective cohort study. **Methods:** We identified patients with EGC managed at MSK from 2007-2025 whose tumors were dMMR by IHC or MSI-H by next generation sequencing and analyzed patient/tumor characteristics and clinical outcomes in those who received curative-intent therapy (systemic therapy and/or surgery; ICI was first introduced in 2018). Clinical complete response (cCR) was defined as the absence of disease by available clinical, radiographic, and endoscopic assessment. **Results:** A total of 211 patients with localized dMMR/MSI-H EGC were identified, with median follow-up of 48 months (IQR 24-77). Primary tumor sites were stomach (71%), GE junction (17%), and esophagus (12%). Among 122 patients who underwent germline testing, 15 (12%) had Lynch syndrome. Initial treatment was upfront surgery in 85 patients (40%), chemotherapy (chemo) in 68 (32%), ICI alone in 44 (21%), and chemo/ICI in 14 (7%). Among 58 patients treated with ICI +/- chemo, 27 (47%) achieved a cCR. 6 patients underwent surgery despite cCR, with pathologic complete response (pCR) rate of 4/6 (67%); pCR rate in those without cCR was 3/16 (19%), yielding an overall pCR rate of 32%, higher than the pCR rate observed with chemo alone (5/48 [10%]). 21 patients elected for NOM after cCR; among those with $\geq$1 year of follow-up, 16 of 17 (94%) remain alive and surgery-free at 1 year. cCR rates were similar between those receiving ICI alone (45%) and chemo/ICI (50%). Notably, 2/2 (100%) patients treated with dual ICI therapy achieved cCR. Lower cCR rates were observed in patients with shorter time on ICI therapy (5/17 [29%] with $\leq$3 months of ICI vs 14/30 [47%] with $>$ 3 and $<$ 6 months vs 8/11 [73%] with $\geq$6 months) and in those with clinical nodal involvement (6/17 [35%] vs 14/19 [74%] in N0); 3 patients who underwent surgery had pCR at tumor but residual nodal disease. cCR rate was also numerically lower in the 19% of patients with MMR heterogeneity, defined by focal loss of MMR proteins on IHC or discordant MMR status between tissue specimens (4/11 [36%] vs 23/47 [49%] in non-heterogeneous cases). **Conclusions:** In this MSK cohort, ICI induced deep responses in nearly half of patients with localized dMMR/MSI-H EGC. Patients achieving cCR who pursued NOM demonstrated excellent outcomes, with most remaining surgery-free at 1 year, supporting the viability of NOM after careful multidisciplinary review. Total neoadjuvant immunotherapy plus chemotherapy in Borrmann type IV gastric cancer (PERISCOPE-01 study): An open-label, single-arm, phase 2 trial. First Author: Haibo Qiu, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China

Background: Borrmann type IV (Borrmann-IV) gastric cancer (GC), or linitis plastica, is marked by diffuse infiltration, early metastasis, and poor prognosis, with limited benefit from conventional therapies. This study evaluated the efficacy and safety of a total neoadjuvant regimen combining immunotherapy and chemotherapy in Borrmann-IV GC. **Methods:** This trial (NCT06451211) enrolled patients with Borrmagnn-IV gastric cancer without distant metastasis. Participants received a total neoadjuvant regimen consisting of tislelizumab (an anti–PD-1 antibody) combined with platinum-based chemotherapy (oxaliplatin plus capecitabine or S-1) for 6 cycles at 3-week intervals, followed by radical surgical resection. The prespecified primary endpoint was the pathological response rate, defined as tumor regression grade (TRG) 0/1. **Results:** A total of 56 patients were enrolled, all patients had no distant metastasis confirmed by laparoscopic exploration and ascitic fluid cytology. The median age was 58 years; all patients were pMMR. In the efficacy analysis population (n=47), 41 patients completed 5–6 cycles and 6 patients completed 3–4 cycles of preoperative chemotherapy plus immunotherapy, no patients experienced disease progression leading to tumor metastasis during preoperative treatment. 47 patients underwent radical surgical resection, including 42 total gastrectomy, with an R0 resection rate of 98% (46/47). The prespecified primary endpoint of TRG 0/1 was achieved in 32% of patients (15/47; 95% CI, 21%–48%). Notably, 17% (n = 8) achieved pCR (ypT0N0), and 53% (n =25) were ypN0. Pathological response (TRG 0/1) was significantly higher in Lauren intestinal/mixed versus diffuse types (53% vs. 21%; $p < 0.05$), while efficacy was comparable between PD-L1 CPS $\geq$5 and $<$5 (44% vs. 30%). Grade 3/4 treatment-related adverse events occurred in 32% of patients (n=18), mainly thrombocytopenia and liver function impairment. Surgical morbidity (Clavien–Dindo grade II/III) occurred in 10.6% of surgical patients (5/47), including 1 patient with postoperative bleeding and 3 patients with anastomotic leakage; no perioperative mortality was observed. **Conclusions:** Total neoadjuvant tislelizumab plus chemotherapy demonstrated promising efficacy and an acceptable safety profile in patients with Borrmann-IV gastric cancer. Lauren classification may serve as a potential predictive biomarker and warrants further study. Clinical trial information: NCT06451211. Research Sponsor: None.

Perioperative chemotherapy plus disitamab vedotin (RC48) and toripalimab in HER2-overexpressed locally advanced gastric or gastroesophageal junction cancer (PERISCOPE-02): An open-label, single-arm, phase 2 trial. First Author: Xiaojiang Chen, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China

Background: The use of Disitamab vedotin (RC48) and programmed death-1 (PD-1) inhibitor is effective in patients with HER2-expressing advanced gastric or gastroesophageal junction (G/GEJ) cancer. However, their use has not been investigated in patients with localized disease. This trial evaluated the safety and anti-tumor activity of perioperative chemotherapy combined with RC48 and toripalimab in the treatment of locally advanced HER2-overexpressed (defined as IHC 2+ or 3+) G/GEJ cancer. **Methods:** This study was an investigator-initiated, open-label, single-arm, phase 2 trial was conducted at Sun Yat-sen University Cancer Center. Eligible patients with HER2-overexpressed locally advanced G/GEJ cancer received 3-4 cycles of neoadjuvant XELOX plus RC48 and toripalimab, followed by surgery. The primary endpoint was TRG 0/1 after neoadjuvant treatment. This study is registered at Chinese Clinical Trial Registry (ChiCTR2400081677). **Results:** Between July 11, 2024, and July 11, 2025, of 26 patients screened for eligibility, 25 patients were enrolled, all patients had no distant metastasis confirmed by laparoscopic exploration and ascitic fluid cytology, 20 (80%) patients had clinical stage III disease and 5(20%) with stage II. Of these 25 patients, the median age was 58 (IQR, 37-74) years. Tumors were located in the stomach in 21(84%) patients and in the gastroesophageal junction in 4 (16%) patients. The patients with HER2 IHC expression of 2+ and 3+ was 21 (84%) and 4 (16%) respectively. 15 (60%) patients had the PD-L1 CPS of 1 or more, 24 (96%) patients were pMMR. The primary endpoint of TRG 0/1 was met in 16 (64%) patients, 9 (36%) patients achieved pCR (ypT0N0), and 24 (96%) were ypN0. 10 (40%) patients experienced grade 3 treatment-related adverse events, the most common treatment-related adverse events were increased ALT or AST (5 [20%] patients) and neutropenia (3 [12%] patients), no grade 4 treatment-related adverse events. Surgical morbidity (Clavien-Dindo II/III) occurred in 2 of 25 (8%) patients, with no 30-day surgical mortality. **Conclusions:** Our findings suggested that perioperative chemotherapy plus RC48 and toripalimab had controllable safety and showed encouraging efficacy in patients with HER2-overexpressed G/GEJ cancer. Clinical trial information: ChiCTR2400081677. Research Sponsor: None.

Whole-genome sequencing–based ultra-sensitive ctDNA molecular residual disease assessment in resectable gastric cancer: Results from MONSTAR-SCREEN-3. First Author: Etsuro Bando, Department of Gastric Surgery, Shizuoka Cancer Center, Nagaizumi, Japan

Background: Circulating tumor DNA (ctDNA) has emerged as a promising biomarker for post-surgical molecular residual disease (MRD) detection; however, its clinical utility in gastric cancer remains poorly defined. The MONSTAR-SCREEN-3 evaluates the clinical performance of a whole-genome sequencing (WGS)–based MRD assay in a pan-cancer cohort, including patients with gastric cancer. **Methods:** MONSTAR-SCREEN-3 is a prospective multicenter study targeting 1,100 patients with solid tumors curative-intent treatment, including gastric cancer. Personalized panels were constructed using Precise MRD (Myriad Genetics), incorporating up to 1,000 tumor-specific alterations identified through whole-genome sequencing (WGS) of matched tumor tissue. Serial plasma samples were collected at baseline, post-neoadjuvant treatment (NAT) when applicable, 1-month post-surgery, every 3 months in year 1, and every 6 months thereafter up to 2 years. Assay performance was evaluated for ctDNA detection and recurrence monitoring. **Results:** As of November 2025, 88 patients with resectable gastric cancer were enrolled. Median age was 69 years (range: 33-87), with female predominance (52.2%). Treatment strategies included upfront surgery (56%, n = 49) and NAT (44%, n = 39). MRD results were available for 220 samples from 57 patients. Clinical staging included Stage I (6%), Stage II (39%), Stage III (51%), and Stage IV (5%). Personalized panel creation succeeded in 100% of patients (57/57), yielding panels containing 588-1,000 alterations. Baseline ctDNA detection was achieved in 96.4% (54/56), with 31.5% at ultra-sensitive levels (tumor fraction $<$ 100 parts per million [ppm]). Post-operative MRD positivity was 7.8% (4/51) at 1 month and 19.5% (8/41) at 3 months, with 25.0% and 50.0% detected at ultra-sensitive levels, respectively. Among 24 patients receiving NAT with pathological assessment, post-NAT MRD status demonstrated 70.0% sensitivity and 100% specificity for pathological complete response (pCR) (MRD positivity, 70% in non-pCR vs. 0% in pCR; $P < 0.01$); 57.1% of MRD-positive cases were detected at ultra-sensitive levels. Two MRD-positive patients developed radiological recurrence, with MRD detection preceding imaging by 2.0 and 4.3 months. **Conclusions:** This WGS-based personalized ctDNA assay demonstrated high technical feasibility and baseline detection sensitivity in gastric cancer, with notable ultra-sensitive detection capability. Post-NAT MRD status demonstrated potential as a predictor of pathological complete response. Extended follow-up and comprehensive longitudinal ctDNA dynamics will be presented. Research Sponsor: SCRUM-Japan Funds (https://scrum-japan.ncc.go.jp/) and Myriad Genetics.

Perioperative durvalumab plus neoadjuvant chemoradiotherapy (CROSS) with and without tremelimumab in esophageal adenocarcinoma: The prospective phase II RICE trial (NCT04159974). First Author: Hans Anton Schloesser, Department of General, Visceral, Thoracic and Transplantation Surgery, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany

Background: Anti-PD-(L)1 is effective in esophageal adenocarcinoma (EGA). The phase II RICE trial (NCT04159974) evaluated the addition of neoadjuvant and adjuvant durvalumab, with or without tremelimumab, to neoadjuvant chemoradiotherapy (CROSS). **Methods:** Patients with locally advanced ($\geq$uT3/Nx or uT2/N+) non-metastatic EGA received two doses of neoadjuvant durvalumab in addition to CROSS, followed by surgery. Adjuvant therapy was randomized 1:1 to durvalumab (12 doses) alone (arm A) or durvalumab plus one dose of tremelimumab (arm B). Translational analyses included HLA-I genotyping, immunohistochemistry, whole-exome sequencing and RNA-sequencing. Clinical outcomes were analyzed in patients who received at least one neoadjuvant dose (mITT) and in those who were randomized and received at least one adjuvant dose (R-mITT). **Results:** In the mITT set (n=56), 95% completed neoadjuvant therapy and 93% underwent resection. The rate of grade $\geq$3 non-hematologic adverse events during neoadjuvant treatment was 25% (13/56 G3, 1/56 G4). Surgery was feasible with a rate of anastomotic leakage of 6%. Major pathological response (MPR, $<$10% viable tumor cells) was achieved in 54% (30/56) including a 23% (13/56) pathological complete response rate (pCR, ypT0/ypN0). The rate of MPR was higher than in propensity-based comparisons with FLOT (25%) and CROSS (37%). Two-year overall (OS) and progression-free (PFS) survival of the mITT set were 72.7% and 53.1%, respectively. After completion of Stage I of the trial (safety run in), 38 patients were included in the R-mITT set. 80% in arm A (durvalumab monotherapy, n=20) and 44% in arm B (durvalumab plus tremelimumab, n=18) completed at least 80% of adjuvant immunotherapy. Combined immunotherapy in the R-mITT set was associated with higher grade $\geq$3 toxicity (22% G3/ 22% G4 in Arm B vs. 15% G3 / 0% G4 in arm A) and did not improve survival (2-year OS/PFS 95.0%/80.0% [arm A] vs. 82.4%/54.2% [arm B]). Tumor mutational burden, heterozygosity of HLA-I, expression of genes related to antigen presentation and T-cell abundance were associated with pathological response. However, discordant cases across all biomarkers underscore the complexity of tumor-immune interactions underlying response to immunotherapy. **Conclusions:** RICE demonstrates safety and feasibility of adding anti-PD-L1 to neoadjuvant CROSS in EGA and shows promising response rates. While CROSS is no longer considered standard of care, our results support efficacy of durvalumab, consistent with results for FLOT plus durvalumab in the MATTERHORN trial. Addition of tremelimumab to durvalumab is not supported by our study. Clinical trial information: NCT04159974. Research Sponsor: Astra Zeneca.

Paclitaxel/cisplatin (TP) vs cisplatin/5-fluorouracil (PF) neoadjuvant chemoradiotherapy for locally advanced esophageal squamous cell carcinoma (ESCC): A randomized trial. First Author: Ta-Chen Huang, National Taiwan University Hospital, Taipei, Taiwan

Background: Neoadjuvant chemoradiotherapy (nCRT) followed by esophagectomy is standard treatment for patients with resectable locally advanced ESCC. A direct comparison of taxane/platinum nCRT versus PF nCRT in prospective randomized clinical trials has never been reported. **Methods:** This is a single-center, open-label, randomized phase II/III trial (registered as NCT0623737 at ClinicalTrial.gov). Patients with locally advanced ESCC (T3/4aN0M0 or T1-3N1-3M0 per AJCC 7th ed.) were randomized 1:1 to TP (paclitaxel 50 mg/m2 weekly plus cisplatin 30 mg/m2 weekly for 5 weeks) or PF (cisplatin 75 mg/m2 day 1 plus 5-FU 1,000 mg/m2 days 1-4 on weeks 1 and 5) chemotherapy with concurrent radiotherapy 45 Gy/25 fractions. Esophagectomy was performed 6 to 10 weeks after completing CRT. Primary endpoint was pathological complete response (pCR) rate for phase II part. If significant pCR benefit of TP versus PF nCRT was found in phase II part, the trial would continue enrolment for the phase III part with overall survival as primary endpoint. **Results:** From Mar 2017 to Jul 2025, 128 patients were enrolled in the phase II part; 6 withdrew before treatment. The intention-to-treat (ITT) population included 122 patients (61 patients per arm); median age was 61 (35-77) years with TP and 58 (39-77) with PF; 90% and 89% were male, respectively. Esophagectomy was performed in 51/61 (84%) vs. 49/61 (80%), and R0 resection was achieved in 43/51 (84%) vs. 36/49 (73%) (p=0.183), respectively. The pCR rate per ITT population was 23/61 (37.7%) with TP vs 17/61 (27.9%) with PF (p=0.247). The difference of pCR rate did not meet the boundary to continue the trial to the phase III part. Median overall survival was 54 vs 43 months (HR 0.76; p=0.284) and median progression-free survival was 33 vs 25 months (HR 0.74; p=0.193) for TP vs PF. Median recurrence free survival was not reached in both arms. Grade 3-4 adverse events during nCRT occurred in 29/61 (47.5%) with TP and 40/61 (65.6%) with PF (p=0.045); most common grade $\geq$3 events were leucopenia (23.0% vs 32.8%), esophagitis (11.5% vs 29.5%), and dysphagia (14.8% vs 27.9%). Postoperative 90-day mortality was 0% in both arms. **Conclusions:** TP-nCRT did not significantly improve pCR versus PF-nCRT in patients with locally advanced ESCC. Clinical trial information: NCT0623737. Research Sponsor: None.

Efficacy and safety outcomes for TP-nCRT versus PF-nCRT.

Phase II study of adjuvant nab-paclitaxel plus S-1 after D2 resection in stage III diffuse gastric cancer (NORDICA study). First Author: Ke Peng, Zhongshan Hospital Fudan University, Shanghai, China

Background: Stage III diffuse-type gastric cancer (DGC) is highly aggressive, with a substantial risk of postoperative recurrence. Adjuvant chemotherapy with nab-paclitaxel plus S-1 (AS regimen) has shown potential efficacy in early studies, but its safety and effectiveness in this high-risk population remain unclear. **Methods:** This single-center, prospective phase II trial enrolled patients with stage III DGC who underwent D2 gastrectomy between January 2020 and October 2023. All patients first received one cycle of S-1 monotherapy as a pre-screening tolerance test. Eligible patients then received adjuvant AS therapy: nab-paclitaxel 260 mg/m² on day 1 every 3 weeks (maximum 400 mg) plus S-1 80–120 mg/day on days 1–14 every 3 weeks for 6 cycles, followed by 8 cycles of S-1 monotherapy. The primary endpoint was 1-year disease-free survival (DFS); secondary endpoints included 3-year DFS, overall survival (OS), and safety. To explore potential molecular correlates of treatment response, whole-exome sequencing was performed on tumor specimens obtained from surgical resection in 24 patients, including 12 patients who experienced recurrence within 2 years (resistant group) and 12 patients with DFS of 2 years or longer (sensitive group). **Results:** The 1-year DFS and OS rates were 84.9% (95% CI, 75.3–95.9%) and 100%, respectively. The 3-year DFS and OS rates were 45.2% (95% CI, 32.5–63.0%) and 62.5% (95% CI, 49.0–79.8%), with a median DFS of 27.7 months (95% CI, 16.5–NR). The most common ≥grade 3 treatment-related adverse events were neutropenia (29.2%), leukopenia (20.8%), rash (6.3%), febrile neutropenia (6.3%), and oral mucositis (4.2%). CDH1 and OBSCN mutations were more frequent in the resistant group, suggesting a potential link to early recurrence. **Conclusions:** Adjuvant AS therapy is feasible and demonstrates promising efficacy for stage III DGC, with an acceptable safety profile. Molecular findings may help identify patients at higher risk of recurrence, supporting further evaluation in larger, randomized phase III trials. Clinical trial information: NCT03977220. Research Sponsor: None.

Interim results from a prospective phase II study of stratified treatment of localized cervical esophageal squamous cell carcinoma by induction immunochemotherapy (SCENIC trial). First Author: Chunguang Li, Department of Thoracic Surgery, Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Definitive concurrent chemoradiotherapy (dCRT) is the standard treatment for cervical esophageal squamous cell carcinoma (CESCC). However, when dCRT fails, salvage esophagectomy is technically challenging. Moreover, optimizing patient selection for dCRT remains an unresolved concern. We propose a stratified screening strategy by incorporating induction immunochemotherapy, aiming to identify suitable candidates for organ-sparing dCRT and timely surgical treatment. **Methods:** This prospective interventional phase II study (SCENIC, ChiCTR2200057732) enrolled patients with clinical stage $T_{2\text{-}4}$ N_{any} M0 (AJCC TNM 8th) resectable CESCC. Eligible participants received induction therapy (IT) of intravenous PD-1 inhibitor tislelizumab (200mg, day 1) plus nab-paclitaxel (100 mg/m^2, day 1,8,15) and carboplatin (area under curve of 5 mg/mL/min, day 1), administered over two 3-week cycles. Four weeks after IT, treatment response was evaluated via endoscopy and PET-CT. Patients were then divided into 3 groups: remarkable response (RR); limited partial response (LPR); and poor response (POR). RR patients received dCRT, while LPR and POR patients underwent radical surgery. Tislelizumab was maintained after dCRT in RR patients, and postoperative adjuvant therapy was dependent on the patient's condition, including chemotherapy, radiotherapy, immunotherapy, or follow-up. The primary endpoint is 2-year event-free survival (EFS). **Results:** From Jul 2022 to Sep 2024, 42 patients were enrolled, with 40 completing two-cycle IT and response evaluation. Post-IT responses were RR in 62.5% (25/40), LPR in 25.0% (10/40), and POR in 12.5% (5/40). All RR patients received subsequent dCRT. In 11 non-RR patients,7 underwent total phryngo-laryngo-esophagectomy(TPLE), 4 received dCRT. Overall, 40 patients (96.0%) had any-grade treatment-related adverse events with leukocytopenia being most prevalent. 5 patients (12.5%) had adverse events of grade 3 or worse. With a median follow-up of 22.3 months (range, 4.5-40.9 months), 2-years EFS rate and overall survival (OS) rate in ITT population was 60.9% and 76.6%. 2-years EFS rate and OS rate in RR group and non-RR group is 78.8% vs 28.0%($p = 0.0011$) and 84.8% vs 70.1%($p = 0.0703$), respectively. **Conclusions:** The 2-year survival of RR patients with dCRT followed by IT appears promising compared to historical data. This stratified strategy of induction immunochemotherapy is effective in identifying candidates suitable for dCRT in patients with resectable CESCC. Clinical trial information: ChiCTR2200057732. Research Sponsor: None.

Perioperative therapy with tifcemailmab plus toripalimab and chemotherapy for resectable thoracic esophageal squamous cell carcinoma (BT-NICE trial): A prospective phase II study. First Author: Chengzhi Ding, Henan Provincial People's Hospital, Zhengzhou, China

Background: Tifcemailmab is a first-in-class humanized monoclonal antibody targeting B- and T-lymphocyte attenuator (BTLA), a novel inhibitory immune checkpoint. This phase II BT-NICE trial represents the first clinical study designed to evaluate the efficacy and safety of a perioperative treatment regimen that combines a BTLA inhibitor (tifcemailmab), a PD-1 inhibitor (toripalimab), and chemotherapy for resectable thoracic ESCC. **Methods:** Patients(pts) with histologically confirmed, resectable thoracic ESCC (clinical stage cT1b-3N1-3M0 or cT2-3N0M0) were enrolled. They received 2 cycles of neoadjuvant therapy with tifcemailmab, toripalimab, and standard chemotherapy (every 3 weeks). Following radical esophagectomy, pts with a pathological complete response (pCR) received up to 15 cycles of adjuvant dual immunotherapy (tifcemailmab + toripalimab). Pts without a pCR received 2 cycles of adjuvant chemotherapy plus dual immunotherapy, followed by dual immunotherapy for up to 13 cycles. The primary endpoint was pCR rate. Secondary endpoints included major pathological response (MPR) rate, objective response rate (ORR), R0 resection rate, adverse events (AEs), event-free survival (EFS), and overall survival (OS). **Results:** Between October 20, 2024, and September 30, 2025, a total of 25 patients were successfully enrolled and underwent surgery after completing neoadjuvant therapy. The median age was 63 years (range 53-75), and 19 (76.0%) were male. Most pts (23/25, 92.0%) had stage III disease. The R0 resection rate was 100% (25/25). The ORR (neoadjuvant) was 96.0% (24/25). The MPR rate was 56.0% (14/25), and the pCR rate was 40.0% (10/25). Pathologic downstaging was achieved in 84.0% of patients. Grade 3-4 treatment-related AEs occurred in 24.0% (6/25) of pts, and grade 3-4 immune-related AEs occurred in 20.0% (5/25); the most common were rash and hypothyroidism. Overall postoperative complications were 20% (5/25). One pt experienced postoperative complications (pulmonary infection and anastomotic leakage). No treatment-related surgical delays or 30-day mortality occurred. **Conclusions:** The BT-NICE regimen demonstrates promising efficacy and is feasible with a manageable safety profile in pts with locally advanced, resectable ESCC. This study provides the first clinical evidence supporting the incorporation of a BTLA inhibitor into a perioperative treatment paradigm for ESCC. Clinical trial information: NCT06588335. The early-onset paradox of gastric cancer: Assessment of geographic clustering, biology, treatment, and outcomes. First Author: Pranati Dharmesh Shah, Loma Linda University, Loma Linda, CA

Background: Early-onset gastric cancer (EOGC), defined as diagnosis before age 45, represents an increasingly recognized and clinically distinct subset of gastric cancer (GC) in the United States. While prior studies largely from Asian cohorts suggest more aggressive tumor biology, contemporary U.S. data characterizing demographic patterns, treatment strategies, geographic variation, and outcomes in resectable disease is limited. **Methods:** Using a U.S. cancer registry (2006–2022), we studied patients aged 18–90 with stage II–III gastric cancer post-gastrectomy. Excluding palliative or incomplete cases, we analyzed overall survival (OS) via Cox models, adjusting for demographics and treatment. P-values were calculated using the Chi-square test to compare racial distribution across age groups. **Results:** Among eligible patients, 1,943 (7.4%) had EOGC. EOGC disproportionately affected Hispanic (23.8%; $p < 0.001$), Black (14.2%; $p < 0.001$), and Asian (10.2%; $p < 0.001$) populations, with White patients accounting for 49.4%, with a male predominance (2:1). Demographic and socioeconomic profiles were distinct within the EOGC population. A greater proportion of EOGC patients resided in areas with a median household income < $38,000 (17.1%; $p = 0.025$). The ≤45 group was more frequently uninsured (7.6%) or Medicaid insured (19.7%) and represented the highest proportion of residents from areas with the lowest educational attainment (21.6%). Geographic clusters emerged in the South/Middle Atlantic and Pacific (TX, CA, AK, HI). EOGC tumors more frequently exhibited diffuse or signet-ring histology (~30%) and advanced nodal involvement. Despite receiving more intensive multimodality therapy, including perioperative or neoadjuvant chemotherapy (74.1%), EOGC patients had lower pathologic response rates and no survival advantage. Median OS was 49.8 months (36-month OS: 58.3%). **Conclusions:** Even with aggressive treatment, EOGC shows worse pathology and no better survival rates than older-onset cases. New U.S. data confirms this aggressive biology and highlights significant demographic and socioeconomic disparities. To improve outcomes, the focus should shift from just intensifying treatment to prioritizing earlier detection and targeted regional screening. Research Sponsor: None.

Demographic characteristics stratified by age groups.

Variable	≤45 Years (n=1943)	46–69 Years (n=15927)	≥70 Years (n=8397)	Total Cohort (N=26267)	p-value

Neoadjuvant cadonilimab plus CapeOX in patients with clinical stage III gastric or esophagogastric junction adenocarcinoma (GC/EGJC): A prospective, single-arm phase II study. First Author: Liying Zhao, Department of General Surgery & Guangdong Provincial Key Laboratory of Precision Medicine for Gastrointestinal Tumor, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Perioperative PD-L1 inhibitor plus chemotherapy has shown survival benefit in PD-L1-positive patients with locally advanced GC/EGJC. However, evidence for neoadjuvant PD-1/CTLA-4 bispecific blockade remains limited. This study evaluates neoadjuvant cadonilimab plus CapeOX in patients with clinical stage III GC/EGJC. **Methods:** This prospective, single-arm phase II study (NCT06310473) enrolled patients (pts) with cT3-4aN1-3M0 disease (AJCC 8th), staged by contrast-enhanced CT and staging laparoscopy with peritoneal cytology to exclude peritoneal metastasis and positive peritoneal cytology (CY1). Pts received cadonilimab (10 mg/kg) plus standard-dose CapeOX every 3 weeks for 3 cycles. Pts without progressive disease on repeat CT and laparoscopy underwent curative-intent surgery, followed by 3-5 cycles of adjuvant CapeOX. The primary endpoint was the pathologic complete response rate (pCR, defined as no residual tumor in stomach and lymph node). The data cutoff was January 15, 2026. **Results:** From May 2024 to August 2025, 30 pts with GC/EGJC were enrolled (GC, n = 21; EGJC, n = 9); 83.3% (25/30) were cT4a and 73.3% (22/30) were cN2-3. PD-L1 CPS $<$ 1 was observed in 14.8% (4/27) of evaluable pts. All pts completed 3 neoadjuvant cycles. Three pts did not undergo surgery: one refused resection and subsequent antitumor therapy after achieving a cCR to neoadjuvant therapy; one had a PR and continued systemic therapy; and one had PD with liver invasion on repeat laparoscopy and initiated second-line therapy. The other 27 pts underwent resection; one had CY1 on postoperative assessment and was considered PD, with an R0 resection rate of 96.3% (26/27). The pCR and major pathologic response (MPR) rates were 22.2% (6/27) and 37.0% (10/27), respectively. The tumor downstaging rate was 74.1% (20/27), including a ypN0 rate of 55.6% (15/27). Adjuvant therapy was administered in 23/27 (85.2%), with four pts still on therapy. Treatment-related adverse events occurred in 100% (30/30), including grade$\geq$3 events in 20.0% (6/30). Notable events included one perioperative cardiovascular death (G5); one pulmonary embolism (G3) diagnosed 5 weeks postoperatively that resolved with anticoagulation; one patient with concomitant anastomotic leakage (G4), intra-abdominal infection (G4), and immune-related adrenal insufficiency (G2) who recovered after endoscopic covered-stent placement and conservative management; additional G3 events included ascites, neutropenia, and peripheral neuropathy (n = 1 each). No postoperative recurrence was observed among resected pts at data cutoff. **Conclusions:** Neoadjuvant cadonilimab plus CapeOX appears safe and effective in patients with clinical stage III GC/EGJC, achieving a moderate pCR rate and warranting further exploration of neoadjuvant immunochemotherapy combination strategies. Clinical trial information: NCT06310473. Research Sponsor: None.

Neoadjuvant adebrelimab combined with chemotherapy in locally advanced esophageal squamous cell carcinoma: A single-arm, phase II trial. First Author: Chao Wu, Department of Medical Oncology, Senior Department of Oncology, Chinese PLA General Hospital, Beijing, China

Background: Neoadjuvant therapy is the standard treatment for patients with locally advanced resectable esophageal squamous cell carcinoma (ESCC). This study evaluated the efficacy and safety of adebrelimab (anti-PD-L1 antibody) combined with neoadjuvant chemotherapy and explored immune correlates associated with treatment response (ChiCTR2400085858). **Methods:** Patients with locally advanced ESCC (cT1b-T2N+M0 or cT3-4NanyM0) received three preoperative cycles of adebrelimab (1200 mg, IV, d1, Q3W) plus nab-paclitaxel (125 mg/m^2, IV, d1, d8, Q3W) and carboplatin (AUC 5 mg/mL/min, IV, d1, Q3W). The primary endpoint was pathological complete response (pCR). Secondary endpoints included major pathological response (MPR), R0 resection rate, disease-free survival (DFS), overall survival (OS) and safety. PD-L1 expression was measured by immunohistochemistry using the combined positive score (CPS). Multiplex immunohistochemistry was performed to assess spatial immune microenvironment changes. **Results:** Forty-three patients were enrolled from October 2023 to June 2025. The median age was 61 years (range, 42-75), and 39 patients (91.0%) were male. Patients with cStage II/III/IVA were 6/16/22. Among the 35 patients who underwent surgery, all achieved R0 resection (100%), with pCR and MPR rates of 22.9% (8/35) and 45.7% (16/35), respectively. The median follow-up was 13.2 months (range 2.4-21.9), with 1-year DFS and OS estimates of 94.2% (95%CI: 86.7%-100.0%) and 86.8% (95%CI: 76.5%-98.4%). Patients with PD-L1 CPS $\geq$ 10 (57%, 20/35) demonstrated a higher pCR rate compared with those with PD-L1 CPS $<$ 10 (43%, 15/35), specifically 30% (6/20) vs 13.3% (2/15). Multiplex immunohistochemistry revealed distinct spatial immune remodeling during neoadjuvant therapy. At baseline, PD-L1 expression was predominantly associated with CD11b$^+$ myeloid cells in peritumoral regions and was enriched in good responders (TRG 0-1), accompanied by higher peritumoral CD3$^+$ T-cell infiltration. Post-treatment analyses demonstrated divergent T-cell dynamics, with decreased peritumoral T-cell density in good responders (TRG 0-1) and increased infiltration in poor responders (TRG 2-3). Treatment-related adverse events were consistent with the known safety profile. The most common treatment-related grade 3/4 AEs were leukopenia (41.9%), alopecia (27.9%), thrombocytopenia (9.3%), anemia (7.0%), and hepatic dysfunction (2.3%). **Conclusions:** Neoadjuvant adebrelimab combined with chemotherapy demonstrated promising efficacy and manageable toxicity in patients with locally advanced ESCC. Myeloid-associated PD-L1 expression and treatment-induced T-cell redistribution may represent immune correlates of response and warrant further investigation. Clinical trial information: ChiCTR2400085858. Research Sponsor: None.

Neoadjuvant tislelizumab plus oxaliplatin and S-1 for locally advanced Siewert type II esophagogastric junction adenocarcinoma: A prospective multicenter phase II study. First Author: Yanzhao Xu, Department of Thoracic Surgery, The Fourth Hospital of Hebei Medical University, Shijiazhuang, China

Background: Adenocarcinoma of the esophagogastric junction (AEG) is a malignant tumor with high morbidity and mortality globally. Among subtypes, Siewert type II AEG remains a clinical challenge owing to its unique anatomical location and distinct clinicopathological features. This study aimed to evaluate the efficacy and safety of Tislelizumab in combination with oxaliplatin and S-1 as neoadjuvant therapy for patients with locally advanced Siewert type II AEG. **Methods:** This is a prospective, multicenter clinical trial. Eligible patients were aged 19-75 years with pathologically confirmed Siewert type II adenocarcinoma of the esophagogastric junction, clinical stage T2-4N0-3M0, ECOG performance status 0-1, and adequate major organ function. All patients received 3 cycles of neoadjuvant therapy consisting of: tislelizumab (200 mg, D1, Q3W), oxaliplatin (130 mg/m², D1, Q3W), and S-1 (40-60mg based on BSA, po, bid, D1-14, Q3W). Following efficacy evaluation, patients underwent resection of the esophagogastric junction adenocarcinoma 4-8 weeks after completion of neoadjuvant therapy. The primary endpoint is pathologic complete response (pCR). Secondary endpoints include major pathologic response (MPR), objective response rate, R0 resection rate, overall survival (OS), disease-free survival (DFS), and safety. **Results:** As of June 2025, a total of 40 patients were enrolled in this study. The median age was 66 years (range, 37-76), 87.5% were male, and 92.5% had an ECOG performance status of 0. Among them, 87.5% (n = 35) of the patients completed 3 cycles of neoadjuvant therapy. The remaining 5 cases completed 1 (n = 1, due to grade$\geq$3 TRAEs), 2 (n = 2, due to grade$\geq$3 TRAEs and patient decision, respectively), and 4 (n = 2, patient decision) cycles of treatment. All patients underwent resection of the esophagogastric junction adenocarcinoma. The R0 resection rate was 97.5% (39/40), with no patients requiring re-operation or experiencing perioperative mortality. The pathologic complete response (pCR) rate was 25% (10/40). The primary tumor pCR rate reached 30% (12/40), and the major pathologic response (MPR) rate was 37.5% (15/40). Treatment-related adverse events (TRAEs) of any grade occurred in 95% (38/40) of patients, with grade $\geq$3 TRAEs observed in 15% (6/40). **Conclusions:** Neoadjuvant therapy with Tislelizumab in combination with oxaliplatin and S-1for locally advanced Siewert type II esophagogastric junction adenocarcinoma yields a favorable pathological complete response (pCR) rate and shows a good safety profile. Clinical trial information: ChiCTR2300075638. Research Sponsor: Excellent Talents Program of the Department of Finance of Hebei Province; ZF2025209.

SCALE-2: A phase 2 trial evaluating neoadjuvant short-course radiotherapy combined with chemotherapy and toripalimab in resectable locally advanced esophageal squamous cell carcinoma. First Author: Ning Jiang, Jiangsu Cancer Hospital & Jiangsu Institute of Cancer Research & The Affiliated Cancer Hospital of Nanjing Medical University, Nanjing, Jiangsu, China

Background: The SCALE-1 Phase Ib trial demonstrated that short-course neoadjuvant radiotherapy combined with toripalimab and chemotherapy, followed by esophagectomy, exhibited manageable toxicity and promising efficacy in patients (pts) with resectable locally advanced ESCC (RLaESCC). This Phase II trial aims to further valuate efficacy and safety of this novel short-course regimen in a larger cohort. **Methods:** RLaESCC pts with clinical stages cT3-4aN0M0/cT1-4aN+M0 received neoadjuvant paclitaxel (135 mg/m^2), carboplatin (AUC=5), and toripalimab (240 mg) every 3 weeks for two cycles. Short-course neoadjuvant radiotherapy (30 Gy/12f; 5 days per week) was administered between the two doses of neoadjuvant immune-chemotherapy. Compared to SCALE-1, high-risk nodal regions were selectively included in the irradiation volume. Weekly weight changes were used to assess preoperative waiting time. Esophagectomies were scheduled 8-10 weeks after completing neoadjuvant treatment. The primary endpoint was pathological complete response (pCR) rate, with secondary endpoints included disease free survival (DFS), overall survival (OS) and safety. **Results:** From April 28, 2024 to February 26, 2025, 63 pts were enrolled (intention-to-treat population, ITT), with stage distribution:I (3.2%), II (14.3%), III (63.5%) and IVA (19%). Following the exclusion of 3 pts who refused surgery, pathological assessment of the surgical specimens revealed that 56.7% (34/60) pts achieved pCR (ypT0N0 or ypTisN0) and 91.7% (55/60) achieved MPR. The median number of resected lymph nodes was 19 (range: 6–45). At a median follow-up of 23.9 months (cutoff date: Jan 19, 2026), median OS and DFS were not reached. In the ITT population, the 2-year OS and DFS rates were 90.4% (95% CI: 82.4-98.4%) and 81.5% (95% CI: 70.5-92.5%), respectively. Postoperative complications occurred in 45% (27) pts, with 18.3%(11) experiencing Grade $\geq$3 events. The most frequent Grade 3 and above complications were anastomotic leakage (n=4) (with or without pleural effusion or hemothorax) and airway mucus obstruction (n=4). Moreover, one case of postoperative delirium was observed (Grade IV), and one patient died of septic shock secondary to an anastomotic leak. All 63 pts completed neoadjuvant radiotherapy. However, 2 pts discontinued the second dose of toripalimab, and 16 pts required dose reductions during the second cycle of neoadjuvant chemotherapy. The most frequent grade 3/4 adverse events were neutropenia (n=27, 42.9%) and leukopenia (n=21, 33.3%). Notably, no grade 3 esophagitis or pneumonitis occurred. **Conclusions:** The SCALE regimen demonstrated potent antitumor activity, achieving 56.7% pCR and 91.7% MPR. Favorable 2-year OS and DFS further highlight its potential to improve long-term outcomes for RLaESCC pts. Clinical trial information: NCT05424432. Research Sponsor: None.

Noninvasive detection of early gastric cancer via red blood cell DNA features associated with tumor-induced hematopoietic stress. First Author: Xingyun Yao, School of Life Sciences, Westlake University, Hangzhou, Zhejiang, China

Background: Early detection of gastric cancer (GC) is limited by invasive endoscopy and the low sensitivity of current blood-based biomarkers for early-stage disease. Emerging evidence indicates that GC engages in complex crosstalk with the bone marrow microenvironment, imposing stress on hematopoiesis. Tumor-derived exosomal and inflammatory mediators reprogram transcriptional and epigenetic profiles in hematopoietic progenitors, driving abnormal hematopoiesis and inducing genomic instability. Here, we report a noninvasive strategy for GC detection based on genome-wide profiling of DNA remnants in mature red blood cells (rbcDNA) and validate its performance for early-stage disease across independent multicenter cohorts. **Methods:** We analyzed rbcDNA from 1–2 mL peripheral blood of 865 individuals, including 434 treatment-naive patients with stage I–III GC (~60% stage I) and 431 non-GC controls with benign gastric conditions. Shallow whole-genome sequencing revealed reproducible rbcDNA read-depth features that distinguished GC from non-cancer states. A machine-learning classifier was trained on dimensionally reduced rbcDNA features in a discovery cohort (n = 435), with a cutoff fixed at 90% specificity. The locked model was then evaluated in a test cohort (n = 109) and three independent validation cohorts from distinct medical centers (n = 321). **Results:** In a discovery cohort, we identified GC-associated rbcDNA features that were significantly enriched in hematopoietic regulation and cell-cycle pathways, reflecting systemic hematopoietic stress rather than tumor-derived copy-number alterations. The resulting classifier achieved AUCs of 93% in the discovery cohort and 95% in the test cohort. At the predefined cutoff, the classifier yielded 83% overall sensitivity and 79% sensitivity for stage I GC in the test cohort. Across three independent medical center cohorts, the model achieved sensitivities of 83%, 90%, and 86%, with specificities ranging from 89% to 94%, consistent with the discovery and test cohorts. The assay effectively distinguished early-stage GC from precancerous lesions, including atrophic gastritis and intestinal metaplasia, while showing limited detection in non-gastric solid tumors. Importantly, rbcDNA identified ~80% of GC cases that were negative for conventional serum tumor markers. **Conclusions:** These findings establish rbcDNA as an effective biomarker for accurate, noninvasive detection of early-stage GC. Research Sponsor: None.

Prognostic value of perioperative ctDNA monitoring in patients with esophageal squamous cell carcinoma (ESCC) undergoing neoadjuvant chemotherapy (NAC) and surgery. First Author: Akinori Watanabe, Department of Gastroenterology, Kitasato University School of Medicine, Sagamihara, Japan

Background: Recent results from a multicenter phase II clinical trial (jRCTs031200094) demonstrated that neoadjuvant FLOT (fluorouracil, leucovorin, oxaliplatin, and docetaxel) improves survival outcomes of patients with resectable ESCC. In this analysis, we evaluated the value of circulating tumor DNA (ctDNA) dynamics after FLOT and curative-intent surgery to predict treatment response and long term outcomes. **Methods:** The jRCTs031200094 clinical study enrolled 37 patients with ESCC to receive neoadjuvant FLOT followed by curative-intent surgery. Plasma samples were collected NAC, post-NAC (prior to surgery), and within 2–12 weeks post surgery [molecular residual disease (MRD) window]. A clinically validated, personalized, tumor-informed mPCR-NGS assay (Signatera, Natera, Inc.) was used on the banked specimens for ctDNA detection. Survival analyses were performed to calculate progression-free survival (PFS) stratified by ctDNA status at the post-NAC and post surgery timepoints. **Results:** This retrospective analysis included the 34 patients with ESCC and available ctDNA results. Patients had a median age of 66 years (range: 44–80), and the majority were male (79% [27/34]). Tumor locations included the middle (53%, 18/34), lower (41%, 14/34), and upper esophagus (5.9%, 2/34). The clinical stage distribution was 8.8% (3/34) stage I, 21% (7/34) stage II, 56% (19/34) stage III, and 15% (5/34) stage IV. R0 resection was achieved in 94% (29/31) of resected patients; 3 patients did not undergo esophagectomy due to disease progression or patient preference. Baseline ctDNA positivity was observed in 97.1% (33/34) of patients. Among 33 patients with ctDNA data available at the post-NAC timepoint, ctDNA-positivity was associated with significantly inferior PFS (HR: 3.17, 95% CI: 1.22-8.21; P=0.018), higher rate of lymph node positivity and higher tumor regression grade (TRG). Of the 29 patients with ctDNA data in the MRD window 31.3% (9/29) were ctDNA-positive and ctDNA-positivity in the MRD window was associated with significantly inferior PFS (HR: 5.89; P=0.001) and overall survival (OS; HR: 7.23; P=0.019). In addition, ctDNA dynamics in response to NAC and surgery were highly predictive of long term outcomes. Sustained clearance after NAC correlated with 80% 24m PFS. Inferior survival was observed in patients who remained ctDNA positive after NAC but cleared after surgery (HR 3.17) and in patients without clearance after surgery (HR 7.63). **Conclusions:** This study demonstrates prognostic and predictive value of single timepoint and longitudinal ctDNA status in the neoadjuvant and postsurgical management of patients with ESCC. Persistent ctDNA positivity following NAC and in the MRD window was strongly associated with inferior PFS, and early ctDNA clearance conferred the most favorable outcomes. Clinical trial information: jRCTs031200094. Research Sponsor: None.

Individualized estimation of benefit from adjuvant docetaxel plus S-1 in stage III gastric cancer using deep learning–based counterfactual survival analysis of the START-2 trial. First Author: Hiroki Sato, OITA University Faculty of Medicine, Yufu, Japan

Background: The START-2 trial demonstrated that docetaxel plus S-1 (DS) was superior to S-1 alone in terms of relapse-free survival (RFS) and overall survival (OS) as adjuvant chemotherapy for patients (pts) with stage III gastric cancer (GC) (J Clin Oncol 2019; Gastric Cancer 2022). We conducted the START-2 AR study, a retrospective analysis, to develop a neural network–based model for predicting RFS and estimating individual-level treatment benefit. **Methods:** Among 912 pts enrolled in the START-2 trial, 599 provided written informed consent to participate in the START-2 AR study. Pts were randomly divided into training (70%) and test (30%) cohorts. Missing data were addressed using multiple imputation. A deep learning–based Cox proportional hazards model was trained in the training cohort and evaluated in the test cohort. Using this model, we estimated individual-level treatment benefit among pts in the DS group, quantified as the difference in restricted mean survival time (dRMST) between counterfactual survival curves comparing DS with S-1 alone. Subsequently, a LightGBM regressor was applied to identify clinicopathological factors associated with treatment benefit using SHapley Additive exPlanations (SHAP). In an exploratory analysis, the top-ranked variables were used to identify a subgroup with limited additional benefit from DS. **Results:** Among 599 pts (training cohort, n = 419; test cohort, n = 180), 249 RFS events were observed (174 and 75 events, respectively). The pooled Antolini C-index was 0.686 (95% confidence interval [CI], 0.643–0.726) in the training cohort and 0.628 (95% CI, 0.565–0.697) in the test cohort. The estimated dRMST in the DS group was 2.71 months (95% CI, 2.58–2.84). SHAP analysis of dRMST indicated that a lower number of metastatic lymph nodes, a higher platelet count, a higher number of dissected lymph nodes, and differentiated histology were the key factors associated with a smaller dRMST, indicating limited treatment benefit. When continuous variables were dichotomized at their median values and pts were stratified by the cumulative number of these four factors, the subgroup with < 3 factors (n = 454) showed significantly improved RFS with DS compared with S-1 alone (hazard ratio [HR], 0.67; 95% CI, 0.51–0.88; p = 0.004). In contrast, no significant benefit was observed in the subgroup with ≥ 3 factors (n = 145; HR, 1.32; 95% CI, 0.70–2.50; p = 0.396). **Conclusions:** Using a deep learning–based counterfactual dRMST framework, we identified a subgroup of pts with resected stage III GC who derived limited additional benefit from adjuvant DS therapy. Stratification based on four clinicopathological factors may facilitate personalized de-escalation of DS treatment. External validation in independent cohorts is warranted. Clinical trial information: UMIN000011438. Research Sponsor: Taiho Pharmaceutical Co., Ltd.

Long-term survival results of perioperative chemoimmunotherapy with DCF and avelumab in locally advanced gastro-esophageal adenocarcinoma. First Author: Thierry Alcindor, Dana-Farber Cancer Institute, Boston, MA

Background: We have shown that avelumab, an anti-PD-L1 antibody, added to perioperative modified DCF chemotherapy (aDCF regimen), improves the pathologic complete response rate from 7% to 14% in locally advanced gastro-esophageal adenocarcinoma (GEA), in comparison to historical controls from our own institution. Little is known about the long-term survival results obtained with perioperative chemoimmunotherapy, a new standard of care. We are here reporting the 5-year survival results of our cohort of patients treated with aDCF. **Methods:** Single-arm phase II study of aDCF given every 2 weeks for 4 cycles before and after surgery with planned sample size of 50 operated patients in order to test hypothesis that pCR rate would improve from 7 to 20%. Main inclusion criteria were: histologically proven GEA, locally advanced disease (cT3-4 and/or N+), adequate organ function, WHO performance status 0-1. Main exclusion criteria were: histology other than adenocarcinoma, metastatic disease (M1), use of immunosuppressants, serious autoimmune disease, daily intake of more than 10 mg of prednisone. Pathological response (Tumour Regression Grade -TRG) was determined by the College of American Pathologists criteria: 0 = complete;1 = near complete/microscopic residual disease; 2 = moderate; 3 = poor/no response. MPR was defined as TRG 0 or 1. Data presented as median (range), KM determined survival. Patients with less than 5 years follow-up and who were disease free / alive were censored. **Results:** One of the 51 patients enrolled into the trial withdrew consent, leaving 50 patients in the survival analysis. Clinical disease burden was high (cT3 44/50, 88%, N+ 31/50, 62%) with 49/50 (98%) completing neoadjuvant aDCF. All patients proceeded to surgery with MPR found in 9/50 (18%) patients. The median follow-up for the cohort was 71.5 months (range 43-105) with an estimated mean DFS and OS of 62.5 months and 68.5 months corresponding to a 5-year DFS and OS of 55.3% and 61.1%. For patients with MPR, 5-year DFS and OS were 100%. There were no new safety signals. **Conclusions:** Perioperative aDCF resulted in long-term survival in the majority of patients treated on our trial, bringing more evidence that chemoimmunotherapy improves outcomes of patients with locally advanced GEA. Those outcomes seem enhanced among patients with MPR. Clinical trial information: NCT03288350. Research Sponsor: EMD/Serono.

Integrating tumor-infiltrating iymphocytes (TILs) in the biomarker landscape of gastroesophageal adenocarcinoma: Going beyond PD-L1. First Author: Filip Van Herpe, Gastrointestinal Oncology Department, University Hospitals Leuven, Leuven, Belgium

Background: Immune checkpoint inhibitors (CPI) are standard of care in perioperative and metastatic gastro-esophageal adenocarcinoma (GEA). PD-L1 scoring remains heterogeneous, with multiple assays and substantial interobserver variability. In breast cancer, immunotherapy responses occur even in PD-L1–negative tumors when tumor-infiltrating lymphocytes (TILs) are present. Exploratory analyses from CM649 suggest that immune infiltration and T-cell signatures may better capture CPI benefit than PD-L1 alone, particularly with ipilimumab–nivolumab. We evaluated TILs and their relationship with established biomarkers in a large GEA cohort. **Methods:** We performed a single-center retrospective study including localized and metastatic GEA patients diagnosed between 2019–2023. Histopathology included MMR status, HER2 (IHC/SISH), PD-L1 CPS, and CLDN18.2 ($\geq$75% tumor cells). TILs were blindly reviewed by an expert pathologist using international TILs-WG guidelines (in press). Baseline characteristics and follow-up were collected until August 2024. **Results:** A total of 230 patients were included (140 localized, 90 metastatic). MMR, PD-L1 CPS, CLDN18.2, and HER2 status were available for all. By Lauren classification, 83 tumors were diffuse (36%), 131 intestinal (57%), and 17 mixed (7%). TILs were dichotomized at $<$ 20% and $<$ 10%. TIL density differed significantly across Lauren subtypes (p = 0.0007): diffuse tumors showed markedly lower infiltration (76% with TILs $<$ 20%) compared with intestinal tumors (60% with TILs $\geq$20%). Using the $<$ 10% cutoff, diffuse tumors again showed lower immune infiltration (78% vs. 22%; p $<$ 0.001). PD-L1 CPS categories ($<$ 1, 1–4, 5–9, $\geq$10) did not differ by subtype. Notably, in CPS $<$ 1 tumors, 28/48 (58%) were TIL-high ($\geq$10%), whereas CPS $\geq$10 tumors showed strong concordance with TIL-high status (25/30, 83%). HER2-positive tumors had a higher proportion of TIL-high cases than HER2-negative tumors (OR 3.55; 95% CI 1.64–8.39; p = 0.0004). CLDN18.2 positivity showed no association with TILs (p = 0.44; OR 0.80; 95% CI 0.46–1.37). **Conclusions:** Using international TILs-WG guidelines, TIL assessment is feasible in routine GEA pathology. TIL density varied significantly across Lauren subtypes, with diffuse tumors showing consistently low immune infiltration. PD-L1 CPS did not reflect these differences and showed substantial discordance with TILs, particularly in PD-L1–negative but TIL-high tumors, suggesting potential CPI sensitivity. HER2 positivity, but not CLDN18.2, was associated with higher TIL levels. These findings support further evaluation of TILs alongside PD-L1 CPS/TAP score as improved predictive biomarkers for anti-PD-1 or anti-PD-1/CTLA-4 therapy. Research Sponsor: None.

Neoadjuvant nivolumab plus ipilimumab and adjuvant nivolumab in patients with localized microsatellite instability-high (MSI)/mismatch repair deficient (dMMR) oeso-gastric adenocarcinoma: Long-term follow-up of the GERCOR NEONIPIGA phase II study. First Author: Thomas Samaille, Sorbonne University; Department of Medical Oncology, Saint-Antoine Hospital, AP-HP, INSERM 938, SIRIC CURAMUS, Paris, France

Background: Neoadjuvant nivolumab and ipilimumab in localized MSI/dMMR gastric cancer were evaluated in the NEONIPIGA study (NCT04006262). The primary endpoint was pathological complete response (pCR) and has been previously reported. Here, we report on the long-term follow-up analysis and the secondary objectives of event-free survival (EFS) and overall survival (OS). **Methods:** This phase II, single-arm study evaluated neoadjuvant nivolumab 240 mg q2w x 6 and ipilimumab 1 mg/kg q6w x 2, followed by surgery 5 weeks ($\pm$1 week) after the last injection of nivolumab and adjuvant nivolumab 480 mg q4w x 9 in patients with resectable MSI/dMMR, T2-T4 NxM0 oeso-gastric adenocarcinoma. EFS and OS were evaluated through Kaplan-Meier curves. **Results:** 32 patients were included: 16 (50%) with gastric location and 16 (50%) with gastro-esophageal junction; 28 (88%) were initially classified as usT3 and four (12%) as usT2; 23 (72%) were lymph node positive. Three patients did not undergo surgery (one metastatic progression, two refusals). 27 (84%) patients completed the planned 6 cycles of neo-adjuvant therapy, and 14 (44%) received the full neoadjuvant and adjuvant treatment. Median follow-up was 48.3 months (44.8-52.0). In the ITT population, 4-year OS was 84.1% (65.8-93). In the population eligible for surgery, 4-year EFS was 83.5% (64.8-92.8). Only one patient (classified as ypT0N1 and TRG1b at surgery) relapsed with cerebral metastases 29 months after initiation of neoadjuvant treatment. Six deaths were reported, including two related to gastric cancer (one post-operative due to surgery complications, one from cerebral metastases). The four remaining deaths were unrelated to gastric cancer or treatment toxicity and were due to pulmonary infections (n = 2; 33 and 60 months after initiation of neoadjuvant treatment), perforation of a strangulated hernia (13 months), and metastatic tongue cancer (30 months). All three patients without surgery achieved a clinical complete response after immunotherapy (including one deceased patient reported above). Combined with the 17 (59%) patients in pCR previously reported, 20 of 32 (62.5%) patients achieved complete response. No new safety signals were reported during extended follow-up. **Conclusions:** Neoadjuvant nivolumab and ipilimumab before surgery and adjuvant nivolumab in localized MSI/dMMR oeso-gastric adenocarcinoma achieved a high curative rate. These findings strongly support further investigation of a watch-and-wait approach in case of clinical complete response after immune checkpoint inhibitors, which is currently being evaluated in the DEWI GERCOR phase II study (NCT06059495). Clinical trial information: NCT04006262. Research Sponsor: BMS.

Neoadjuvant cadonilimab plus chemotherapy for locally advanced gastric/gastroesophageal junction cancer: A single-arm, phase II trial. First Author: Pengfei Zhang, West China Hospital, Sichuan University, Chengdu, Sichuan, China

Background: Cadonilimab plus chemotherapy is a promising treatment option in the first-line setting of gastric cancer; however, its activity in the neoadjuvant setting remains unclear. The study evaluated the efficacy and safety of cadonilimab plus chemotherapy in neoadjuvant treatment for locally advanced gastric or gastroesophageal junction (G/GEJ) cancer. **Methods:** Eligible patients with locally advanced G/GEJ cancer (cT3-4a N+ M0) were enrolled and treated with 3 cycles of SOX chemotherapy (oxaliplatin 130mg/m^2, IV, d1; S-1 40-60 mg, PO, bid, d1-d14; q21d) plus cadonilimab (10mg/Kg IV, d1, q21d), followed by radical gastrectomy with D2 lymphadenectomy. The primary endpoint was pathological complete response (pCR) rate, and the secondary endpoints included R0 resection rate, major pathological response (MPR) rate, 2-year disease-free survival (DFS) rate, 2-year overall survival (OS) rate and safety. Moreover, a single-cell spatial proteomic atlas was constructed to identify the mechanisms of immune resistance in patients with G/GEJ cancer who received neoadjuvant cadonilimab combined with SOX chemotherapy. **Results:** From September 2023 to July 2024, 45 patients were screened, and 37 patients were enrolled in this study. The median age was 58 years (range 27–72). 26 (70.3%) patients had cT4a disease, and 32 (86.5%) patients had a primary tumor in the stomach. All patients underwent preoperative evaluation. Two (5.4%) patients refused surgery, and 35 (94.6%) patients underwent gastrectomy with D2 lymphadenectomy. pCR (TRG1a) was observed in nine patients (ITT set: 24.3% (95% CI: 11.8% to 41.2%); surgery set: 25.7% (95% CI: 12.5% to 43.3%)). The MPR (TRG1a/b) rate was 70.3% (95% CI: 53.0% to 84.1%). As of the cutoff date of January 1, 2026, the median follow-up time was 24.1 months (range 14.3-28.4). One patient who refused surgery died, and three patients in the surgery set relapsed. 2-year DFS and OS rates were 90.2% and 97.3, respectively. Most of the TRAEs were grade 1-2. Nine (24.3%) patients experienced grade 3-4 TRAEs. The most common grade 3-4 TRAEs were thrombocytopenia (n = 4, 10.8%) and rash (n = 2, 5.4%). Single-cell spatial atlas demonstrates that recurrence following cadonilimab combined with SOX chemotherapy in gastric cancer is associated with distinct spatial immune ecosystems, which is characterized by immune deserts or suppressive fibrotic–myeloid networks that spatially and functionally incapacitate CD8 T cells. **Conclusions:** Based on the encouraging pCR rate, survival outcome and manageable safety in this study, cadonilimab plus SOX chemotherapy is a promising neoadjuvant treatment option for patients with locally advanced gastric cancer. Moreover, targeting stromal and myeloid components may be necessary to unlock the full therapeutic potential of immune checkpoint blockade. Clinical trial information: NCT05948449. Research Sponsor: None.

Diagnostic and predictive utility of peritoneal tumor DNA in gastroesophageal cancer: A prospective multicenter study. First Author: David Liu, Divsion of Cancer Surgery, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: Gastric and gastroesophageal cancers (G/GEC) commonly spread to the peritoneum. Accurate peritoneal staging is critical for guiding intent and therapy, however staging PET, CT and peritoneal cytology have low sensitivity for peritoneal micrometastases. Whilst circulating tumor DNA (ctDNA) poorly correlates with peritoneal disease, tumor DNA from the peritoneum (ptDNA) may identify early peritoneal metastases missed by conventional staging. We developed a tumor-informed whole-genome sequencing (WGS) platform to detect ptDNA and evaluated its accuracy in diagnosing peritoneal metastases and predicting survival in curative-intent G/GEC. **Methods:** This Australian multicenter prospective cohort study enrolled patients receiving curative-intent treatment for G/GEC (upfront surgery, perioperative FLOT or neoadjuvant CROSS/nivolumab). Tumor biopsies, blood, and peritoneal lavage fluid were collected at staging laparoscopy, and at surgery for those receiving neoadjuvant therapy. Tumor-informed WGS was used to identify ctDNA and ptDNA, which were correlated with disease free survival (DFS), peritoneal recurrence free survival (pRFS), non-peritoneal recurrence free survival (npRFS), and overall survival (OS) using multivariate Cox regression. The diagnostic utility of ptDNA for peritoneal metastases was evaluated by comparing true-negative patients ($>$ 2 years disease-free post-surgery alone) with an independently enrolled cohort of true-positive patients (macroscopic/cytology-positive peritoneal disease). **Results:** ptDNA was detected in 28 (30.4%) of 92 consecutive non-metastatic patients (59 with and 33 without neoadjuvant therapy). ptDNA-positivity significantly correlated with advanced cT and (y)pT stage. At a median follow-up of 17 months, there were 12 (13.0%) peritoneal and 10 (10.9%) non-peritoneal recurrences. ptDNA-positivity independently predicted poorer pRFS (HR 26.74, 95%CI 3.94-181.66), DFS (HR 4.51, 95%CI 1.77-11.47) and OS (HR 6.65, 95%CI 1.72-25.76), but not npRFS (HR 0.87, 95%CI 0.16-4.78). Importantly, 9 (60%) patients converted from ptDNA-positive to ptDNA-negative post-neoadjuvant treatment. Patients who remained ptDNA-positive had significantly worse pRFS (3/6 recurrences, HR 45.4, 95%CI 3.5-595.2) than those who were ptDNA-negative (0/25 recurrences). The diagnostic accuracy of ptDNA was validated in 10 true negative and 12 true positive patients. In this cohort, ptDNA achieved 100% sensitivity, specificity, positive and negative predictive values (95%CI 75.8-100%) for detecting peritoneal metastases. ctDNA data will be presented at the meeting. **Conclusions:** Tumor-informed WGS-based ptDNA accurately diagnoses peritoneal disease and predicts peritoneal recurrence post curative-intent treatment, informing its potential to personalize clinical management using intraperitoneal therapies. 4102 Poster Session

Perioperative cadonilimab (AK104) in locally advanced MSI-H/dMMR gastric or gastroesophageal junction adenocarcinoma and colorectal adenocarcinoma: A basket study. First Author: Jiafu Ji, Peking University Cancer Hospital & Institute, Beijing, China

Background: Microsatellite instability-high (MSI-H) / deficient mismatch repair (dMMR) tumors generate abundant neoantigens and are sensitive to PD-1 blockade. However, evidence supporting the use of PD-1/CTLA-4 blockade in the neoadjuvant setting for MSI-H/dMMR gastric and colorectal cancers remains scarce. **Methods:** In this multicenter, single-arm, dual-cohort basket study (NCT04556253), we used a Simon's two-stage design to evaluate perioperative cadonilimab in patients with locally advanced MSI-H/dMMR gastric/gastroesophageal junction (GEJ) or colorectal adenocarcinoma. 29 patients were enrolled in cohort 1 (gastric/GEJ adenocarcinoma) and 18 patients were enrolled in cohort 2 (colorectal adenocarcinoma). The main inclusion criteria include newly diagnosed, histologically confirmed cT3–T4aNxM0 MSI-H/dMMR gastric/GEJ adenocarcinoma or colorectal adenocarcinoma, with an ECOG score of 0-1. Both cohorts received 3 cycles of neoadjuvant cadonilimab (10 mg/kg q3w) followed by radical resection, then 6 cycles of adjuvant cadonilimab (10 mg/kg q3w). The primary endpoint was pathologic complete response (pCR). Secondary endpoints included overall survival (OS), event-free survival (EFS), disease-free survival (DFS), major pathologic response (MPR) rate and incidence of adverse events (AEs). **Results:** As of the data cutoff date of January 24, 2026, the median follow-up was 14.6 months for cohort 1 and 12.6 months for cohort 2. In cohort 1, 2 patients were pathologically confirmed as pMMR prior to treatment. Among the 26 patients (mITT population), pCR rate was 69.2% (95% CI: 48.2%-85.7%), and MPR rate was 80.8% (95% CI: 60.6%-93.4%). The 12-month OS, EFS, and DFS rates were each 100% in mITT population. All 29 patients (ITT population) received neoadjuvant therapy. AEs during neoadjuvant treatment occurred in 24 patients (82.8%), with 3 patients (10.3%) experiencing grade 3-4 AEs. Common AEs (incidence ≥10%) included rash, anemia, constipation, and insomnia, which were primarily grade 1-2. Among the 18 patients (mITT population) in cohort 2, the postoperative pCR rate was 66.7% (95% CI: 41.0%-86.7%), and the MPR rate was 72.2% (95% CI: 46.5%-90.3%). The 12-month OS, EFS, and DFS rates were each 100% in mITT population. All 18 patients (ITT population) received neoadjuvant therapy. AEs during neoadjuvant treatment occurred in 17 patients (94.4%), with 2 patients (11.1%) experiencing grade 3-4 AEs. Common AEs (incidence ≥10%) included rash, infusion-related reaction, anemia, and cough, which were primarily grade 1. No grade 5 AEs were reported in this study. **Conclusions:** Perioperative cadonilimab demonstrates excellent antitumor activity and a manageable safety profile in patients with locally advanced MSI-H/dMMR gastric/GEJ adenocarcinoma and colorectal adenocarcinoma. 4103 Poster Session

Neoadjuvant immunochemotherapy plus thymalfasin in locally advanced gastric cancer: A prospective clinical trial. First Author: Hongda Liu, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Neoadjuvant immunochemotherapy has emerged as a promising strategy for locally advanced gastric and gastroesophageal junction (G/EGJ) adenocarcinoma, but a substantial proportion of patients derive limited benefit. Thymalfasin is an immunomodulatory peptide that may amplify antitumor immunity while attenuating toxicity. We conducted a phase II trial to evaluate anti-PD-1 plus SOX immunochemotherapy combined with thymalfasin as neoadjuvant treatment for G/EGJ adenocarcinoma. **Methods:** The prospective trial enrolled patients aged 18–75 with cStage III G/EGJ adenocarcinoma, ECOG 0–1, and adequate organ function. Treatment included three 21-day cycles of serplulimab (anti-PD-1) plus SOX (S-1 and oxaliplatin) and nine weeks of thymalfasin, followed by curative gastrectomy. The primary endpoint was pathological complete response (pCR). Secondary endpoints included major pathological response (MPR), safety, survival, and other efficacy measures. Peripheral immune remodeling was assessed by flow cytometry, and bulk RNA sequencing of peripheral blood mononuclear cells (PBMCs) interrogated thymalfasin-associated transcriptional programs. **Results:** Thirty patients were enrolled and all underwent curative-intent minimally invasive gastrectomy. pCR was achieved in 30.0% (9/30), and MPR in 56.7% (17/30). ypN0 status was observed in 63.3% (19/30), with N-stage downstaging in 80.0% (24/30). The objective response rate was 73.3% and the disease control rate was 100.0%. At a median follow-up of 14.0 months (range 10.0-17.2), only one retroperitoneal nodal relapse had occurred at 14.4 months after diagnosis; no deaths were documented. Any-grade adverse events (AEs) occurred in 93.3% of patients, grade ≥3 AEs in 26.7%, and immune-related AEs in 23.3%, with no grade ≥3 irAEs. Flow cytometry showed expansion of $CD8^+$ T cells with increased CD69 expression and a concurrent reduction in HLA-DR-positive T cells, suggesting dynamic remodeling from broad systemic activation toward a more focused effector or memory response. RNA-seq revealed thymalfasin-associated upregulation of genes involved in antigen processing and presentation, type I interferon signaling, innate immune sensing, and immune metabolic reprogramming, and identified immune co-expression modules linked to treatment and response. **Conclusions:** Neoadjuvant serplulimab, SOX, and thymalfasin produced encouraging pathological response, substantial nodal clearance, and an acceptable safety profile in stage III G/EGJ adenocarcinoma. Peripheral immune and transcriptomic profiling are consistent with a hypothesis in which thymalfasin may help preserve and coordinate systemic antitumor immunity without excessive toxicity. These findings warrant confirmation in larger randomized trials. Clinical trial information: NCT06461910. CheckMate-9DW 4-year follow-up: Overall survival by depth of response and outcomes in long-term survivors. First Author: Aiwu Ruth He, Columbia University Irving Medical Center, New York, NY

Background: Nivolumab plus ipilimumab (NIVO + IPI) was globally approved as a first-line (1L) treatment for unresectable hepatocellular carcinoma (HCC) based on the phase 3 CheckMate 9DW trial (NCT04039607). We report 4-year follow-up results and overall survival (OS) by depth of response (DpR). **Methods:** Methods were reported previously (Yau T. *Lancet* 2025). Briefly, adults with previously untreated unresectable HCC were randomized 1:1 to receive NIVO + IPI (then NIVO for ≤ 2 years) or lenvatinib/sorafenib (LEN/SOR). OS analyses were done by best percentage change in tumor burden from baseline. We also present exploratory analyses on long-term survivors (survival ≥ 4 years after randomization). **Results:** A total of 668 patients (pts) were randomized to NIVO + IPI (n = 335) or LEN/SOR (n = 333); among 325 pts treated with LEN/SOR, 275 (85%) received LEN. At a median (range) follow-up of 52.5 (44.0–66.1) mo, NIVO + IPI continued to show OS benefit (95% CI) vs LEN/SOR (HR 0.78 [0.65–0.93]) with higher objective response rate (ORR; 95% CI) by blinded independent central review (BICR; 36% [31–42] vs 13% [10–17]) and more durable responses. Pts with deeper tumor reduction had numerically improved median OS on both NIVO + IPI and LEN/SOR; the trend was more pronounced with NIVO + IPI specifically in pts with tumor shrinkage ≥ 30% (Table). More pts treated with NIVO + IPI (n = 62) were long-term survivors vs pts treated with LEN/SOR (n = 33). In long-term survivors, ORR by BICR was higher with NIVO + IPI vs LEN/SOR (76% vs 24%), with higher rates of complete response (CR; 21% vs 6%; Table); median duration of response was not reached in either group. Among long-term survivors, median (range) treatment-free interval was 23.3 (0.1–56.6) mo with NIVO + IPI and 0.5 (0.1–54.0) mo with LEN/SOR; 26 of 62 (42%) and 2 of 33 (6%) patients, respectively, were off study treatment and remained free from subsequent treatment. Baseline characteristics and incidence of TRAEs in long-term survivors were consistent with all randomized pts. **Conclusions:** 1L NIVO + IPI continued to show sustained efficacy benefit vs LEN/SOR in unresectable HCC with no new safety concerns at the 4-year follow-up. These analyses suggest deeper responses with NIVO + IPI may be associated with improved survival outcomes. Long-term survivors treated with NIVO + IPI had higher ORR and CR rates vs LEN/SOR, and were more likely to remain free of subsequent treatment. These results reinforce NIVO + IPI as a 1L treatment for unresectable HCC. Clinical trial information: NCT04039607. Research Sponsor: Bristol Myers Squibb.

First-line rilvegostomig (R) + chemotherapy (CTx) in advanced biliary tract cancer (BTC): Updated analysis of GEMINI-Hepatobiliary substudy 2 cohort A. First Author: Jian Zhou, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Addition of PD-(L)1 inhibitors to CTx has transformed advanced BTC treatment but survival is limited for most patients (pts). R is a monovalent, Fc-reduced PD-1xTIGIT bispecific antibody that delivers coordinated and synchronous PD-1 and TIGIT blockade on immune effector cells. The primary analysis of substudy 2 Cohort A of GEMINI-Hepatobiliary (NCT05775159), a global phase 2 study evaluating R + CTx in pts with advanced BTC, demonstrated promising efficacy and a manageable safety profile. We report updated analyses after ≥18 months of follow-up for the last enrolled pt. **Methods:** Pts ≥18 years with previously untreated unresectable/metastatic BTC and ECOG PS 0/1 received intravenous R every 3 weeks (Q3W; ≤2 years) + gemcitabine 1000 mg/m^2 + cisplatin 25 mg/m^2 on days 1 and 8 Q3W (≤8 cycles). Coprimary endpoints were 6-month progression-free survival (PFS) and safety/tolerability. Secondary endpoints included median PFS, objective response rate (ORR), disease control rate (DCR), duration of response (DoR), and overall survival (OS). Response and progression were investigator-assessed per RECIST v1.1. **Results:** As of Oct 24, 2025, the median follow-up for OS was 16.2 months (IQR 10.4–21.5); 6 pts (20.0%) received ≥20 cycles of R. Median OS was 16.8 months (95% confidence interval [CI] 11.0–not calculable [NC]) overall; 18-month OS was 44.8% (95% CI 26.5–61.6). Median OS was > 13 months across all subgroups based on age (< 65/≥65 years), ECOG PS (0/1), geography, initially unresectable/recurrent disease at enrollment, and primary tumor location (gallbladder or bile duct). Two unconfirmed responses were identified after > 85 weeks follow-up: one complete and one partial response. The safety profile was consistent with the primary analysis. The most common treatment-related adverse events (AEs) were anemia (53.3%), neutrophil count decreased (50.0%), and platelet count decreased (43.3%). Detailed efficacy and safety data are in the Table. **Conclusions:** R + CTx demonstrated promising efficacy and a manageable safety profile. This study and phase 3 studies of R in BTC (ARTEMIDE-Biliary01, ARTEMIDE-Biliary02, DESTINY-BTC01) are ongoing. Clinical trial information: NCT05775159. Research Sponsor: AstraZeneca.

Safety and efficacy of puxitatug samrotecan (Puxi-Sam, AZD8205) in patients with biliary tract cancer (BTC): A first-in-human phase 1/2a study (BLUESTAR). First Author: Do-Youn Oh, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, South Korea

Background: B7-H4 is a transmembrane glycoprotein that negatively regulates T-cell function and is highly expressed in many cancers, including BTC, making it an attractive target for an antibody–drug conjugate (ADC). Puxi-Sam (also known as AZD8205), a novel B7-H4–directed topoisomerase I inhibitor (TOP1i) ADC, demonstrated favorable toxicity and promising antitumor activity during the dose escalation phase of the first-in-human Phase 1/2a BLUESTAR (NCT05123482) trial. Here, we report the pooled analyses for patients with BTC in the dose-escalation and dose-expansion phase of BLUESTAR. **Methods:** Eligible patients were ≥18 years old with nonresectable, recurrent, or metastatic B7-H4-positive BTC, with measurable disease per RECIST v1.1, and an ECOG performance status of 0 or 1. B7-H4 positivity was defined as ≥25% tumor cell staining by central immunohistochemistry in archival tumor samples. Patients must have received prior adequate standard-of-care therapy; prior treatment with a TOP1i was not allowed for patients in the dose-expansion phase. Patients received Puxi-Sam 2.4 mg/kg IV Q3W until disease progression, unacceptable drug-related toxicity, or consent withdrawal. The primary objective was assessment of safety; secondary objectives included assessment of antitumor activity. **Results:** As of 30 October, 2025, 20 patients received 2.4 mg/kg Puxi-Sam. The median (min–max) age was 61.5 years (44–88) and patients had received a median (min–max) of 2 (1–4) prior lines of treatment. Sixteen (80.0%) patients had treatment-related adverse events (TRAE), most commonly nausea (55.0%), and anemia (50.0%). Eleven (55.0%) patients had Grade ≥3 TRAEs, most commonly anemia (50.0%) and neutropenia (30.0%). Dose interruptions, reductions, and discontinuations due to TRAEs were required in six, two, and one patient, respectively. Two patients achieved a partial response (PR), corresponding to a confirmed objective response rate (ORR) of 10.0%. Disease stabilization was observed in a meaningful proportion of patients; 10 patients (50%) had stable disease (SD), and 12-week disease control rate (DCR) was 25.0% (5/20). Median progression-free survival (PFS) was 2.2 months, with a median follow-up of 2.2 months, supporting early signals of disease control (Table). **Conclusions:** Puxi-Sam demonstrated a favorable safety profile and showed modest clinical activity with prolonged disease stabilization observed in a subset of heavily pretreated patients with nonresectable, recurrent, or metastatic BTC. Clinical trial information: NCT05123482. Research Sponsor: AstraZeneca.

Efficacy and safety of transarterial chemoembolization combined with donafenib for hepatocellular carcinoma with rupture and bleeding: A retrospective, cohort study. First Author: Qi Zhang, Shiyan Renmin Hospital, Shiyan, China

Background: The incidence of hepatocellular carcinoma (HCC) ranks 6th in the world, and rupture and bleeding of HCC is its fatal complication. Transarterial chemoembolization (TACE) is an effective measure for acute hemostasis, but the prognosis of TACE alone is limited. The ZGDH3 study showed that donafenib was the only targeted agent with better overall survival (OS) than sorafenib in monotherapy for HCC. This study aims to investigate the efficacy and safety of TACE combined with donafenib compared with TACE monotherapy in the treatment of HCC with rupture and bleeding. **Methods:** This study retrospectively analyzed patients with rupture and bleeding of HCC who received TACE combined with donafenib or TACE monotherapy in Qinghai University Affiliated Hospital from January 2022 to August 2024. Patient criteria for inclusion: (1) Definitive diagnosis of HCC with rupture and bleeding by imaging and laboratory examination; (2) Child-Pugh class A and B; (3) No previous systemic therapy. The efficacy and safety were evaluated by mRECIST and CTCAE 5.0. **Results:** A total of 62 patients were included in the study, of whom 35 in the TACE monotherapy group and 27 in the TACE plus donafinib group, and there was no significant difference in baseline characteristics between the two groups. Patients in TACE plus donafenib group demonstrated a significantly higher objective response rate (ORR) compared with TACE monotherapy group (55.6%vs 25.7%, P=0.008). The median progression-free survival (PFS) significantly better than TACE monotherapy group (13.6 months [95%CI: 4.354 - 22.846] vs 4.6 months [95% CI: 1.637 - 7.563]; HR=0.404, P=0.003). The median OS was longer in the TACE plus donafenib group compared to TACE monotherapy group (17.4 months [95%CI: 8.478 - 26.322] vs 7.6 months [95%CI: 1.301 - 13.899]; HR=0.479, P=0.012). Additionally, multivariate COX regression analysis showed that PVTT, Child-Pugh grade, tumor diameter and total bilirubin were independent prognostic factors for OS. The incidence of treatment-related adverse events (TRAEs) significantly higher in TACE plus donafenib group, the most common were skin-related adverse events (37% vs 0%), diarrhea (29.6% vs 0%) and alopecia (18.5% vs 0%), which can be controlled by symptomatic treatment. There were no grade ≥3 TRAEs. But there was no significant difference in the incidence of rebleeding, stomachache and fever. **Conclusions:** TACE combined with donafenib showed significant efficacy and controllable safety in HCC with rupture and bleeding. Research Sponsor: None.

Dual BRAF/MEK inhibition in *BRAF*^{V600E}–mutated biliary tract cancer with exploratory histology-dependent response: A systematic review and meta-analysis. First Author: Neel Parikh, Zydus Medical College and Hospital, Dahod, Gujarat, India

Background: The BRAF V600E mutation defines an actionable subset of rare cancers. Metastatic BTC carries a poor prognosis, with median survival under one year on standard chemotherapy. Given the rarity of BRAF V600E-mutated BTC and the absence of RCTs, rigorous evidence synthesis is needed; existing data for dabrafenib plus trametinib come only from single arm basket trials such as ROAR and NCI-MATCH. The low prevalence of this mutation limits the feasibility of large randomized studies. This SRMA aimed to quantify the efficacy of dual BRAF/MEK inhibition in BTC and explore potential histology dependent differences in response. **Methods:** We performed a systematic review and meta-analysis (SRMA) pooling single arm Phase II basket trial cohorts (N = 53 BTC; N = 17 CNS). Seven case reports were summarized qualitatively and excluded from pooled analyses. The primary endpoint was pooled overall response rate (ORR). A random effects model was used. Subgroup and heterogeneity analyses were performed given the tissue-specific behavior of V600E-driven tumors. Histology was evaluated as an exploratory moderator and heterogeneity was quantified. **Results:** In the pooled cohort of 70 patients (53 BTC and 17 CNS), the overall ORR was 45.3% (95% CI: 24.5-66.9%). Heterogeneity for the BTC subgroup was moderate (I^2 = 62.6%), while overall pooled heterogeneity across all studies was low (I^2 = 14%). ORR in BTC was numerically higher than in Central nervous system (CNS) cohorts (34.9%) but subgroup differences did not reach statistical significance (P = 0.3386). The observed median OS of 13.5 months in the ROAR BTC cohort compares favourably with historical outcomes commonly reported in the 6-12 month range for advanced BTC. The consistency of pooled estimates, despite non-randomized designs, suggests a stable treatment signal while acknowledging that causality cannot be inferred from uncontrolled data. Median progression-free survival was 9.0 months in BTC and 5.5-8.0 months in CNS cohorts. Median OS in the ROAR BTC cohort was 13.5 months (95% CI: 10.4-17.6), exceeding historical expectations. The pooled rate of Grade ≥3 AEs was 59.2%, consistent with the known safety profile of dabrafenib plus trametinib; no treatment-related deaths were reported. Qualitative data from case reports confirmed regression of CNS metastases and feasibility in patients with severe hepatic dysfunction. **Conclusions:** Dual BRAF/MEK inhibition shows clinically meaningful activity in BRAF V600E-mutated BTC, with survival exceeding historical expectations. Exploratory analyses indicate histology-dependent differences, supporting tumor-specific therapeutic stratification. These findings align with growing tissue-agnostic evidence for MAPK inhibition and reinforce the value of routine molecular profiling, though conclusions are limited by small cohorts and single arm studies. Research Sponsor: None.

Real-world treatment patterns and clinical outcomes among cholangiocarcinoma patients treated with futibatinib or pemigatinib. First Author: Amit Mahipal, University Hospitals, Cleveland, OH

Background: Pemigatinib and futibatinib are FGFR2 inhibitors approved by the US Food and Drug Administration in 2020 and 2022, respectively, for the treatment of advanced cholangiocarcinoma (CCA). This study describes demographic and clinical characteristics, and assesses clinical outcomes of real-world CCA patients treated with futibatinib or pemigatinib. **Methods:** This study used deidentified data from electronic medical records and claims from the ConcertAI RWD360 oncology dataset. Patients diagnosed with CCA and with evidence of initial treatment with futibatinib or pemigatinib in 2023 or later (index treatment) were included. Real-world outcomes (real-world overall survival [rwOS], time to discontinuation [rwTTD], and time to next treatment or death [rwTTNTD]) from the index date were described using Kaplan-Meier analysis. Cox regression models were used to adjust for patient characteristics. Adverse medical events of interest (MEI) were identified with ICD codes. **Results:** This study included 122 futibatinib (median age: 64 years; female: 58%; White: 66%) and 93 pemigatinib patients (median age: 66 years; female: 61%; White: 69%). The most common treatment regimen before index was cisplatin + durvalumab + gemcitabine (44% futibatinib and 35% pemigatinib patients). Futibatinib patients had numerically longer median rwOS (10.5 vs. 9.6 months) and median rwTTNTD (6.5 vs. 5.6 months) than pemigatinib patients, though the differences were not statistically significant; median rwTTD was similar in both futibatinib and pemigatinib patients (2.8 vs. 2.8 months); and adjusted hazard ratios were non-significant for all outcomes (Table 1). Futibatinib had numerically higher 6-month rwOS (63% vs. 55%) and 12-month rwOS (42% vs. 36%). Overall, 28% (n=60) of patients experienced MEI during index treatment: 29% (35/122 patients) in the futibatinib group and 27% (25/93) in the pemigatinib group. The most common MEI were (futibatinib vs. pemigatinib) fatigue (8% vs. 16%), diarrhea (10% vs. 5%), and dry eyes (6% vs. 1%). **Conclusions:** This study represents the largest real-world analysis to date of CCA patients treated with FGFR inhibitors. Overall, patient characteristics and MEI were similar in the two treatment groups. Clinical outcomes were also similar in both groups, suggesting that futibatinib is a promising alternative in this patient population. Research Sponsor: Taiho Oncology, Inc.

Tislelizumab combined with donafenib and GEMOX as first-line treatment for advanced biliary tract cancer: A single-arm, phase II study. First Author: Yiming Zhao, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Advanced biliary tract cancer (BTC) progresses rapidly and has a poor prognosis, with a 5-year survival rate of less than 5%. Gemcitabine and oxaliplatin (GEMOX) plus tislelizumab and donafenib as the first-line treatment for advanced BTC has confirmed good safety and preliminary efficacy in our phase I study (NCT04979663). This study aimed to further evaluate the efficacy and safety of GEMOX plus tislelizumab and donafenib. **Methods:** This is a single-arm, phase II trial (NCT05668884). Patients were enrolled if they were 18-75 years old, had stage III/IV cancer (AJCC 8th Edition), were Child-Pugh A/B, had an ECOG PS of 0-1, and had received no prior systemic therapy or tumor-related surgery. Patients were administrated with tislelizumab (200 mg IV on d1 Q3W), donafenib (200mg PO BID) and GEMOX (Q3W up to 8 cycles: gemcitabine 1000 mg/m² IV on d1 and 8, oxaliplatin 100 mg/m² IV on d1). Treatment continued until disease progression or unacceptable toxicity or withdrawal of consent whichever occurred first. The primary endpoint was the objective response rate (ORR) assessed by RECIST v1.1. **Results:** From December 2022 to October 2025, 47 patients were enrolled with a mean age of 60.8 (18 females and 29 males), 35 patients had intrahepatic cholangiocarcinoma, 11 patients had gallbladder carcinoma and 1 patient had perihilar cholangiocarcinoma. The ORR and the disease control rate (DCR) by RECIST 1.1 were 38.3% (18/47) and 93.6% (44/47), respectively. 2 patients underwent subsequent surgery after first-line treatment. The median PFS was 12.1 months (95%CI: 5.1-19.1), 1-year survival rate was 57% (95%CI: 38-76). All patients had treatment-related adverse events (TRAEs), the incidence of grade 3-4 TRAEs was 46.8%, the most common grade 3-4 TRAEs were rash (6/47,12.8%), thrombocytopenia (5/47,10.6 %) and fever (3/47, 6.4%). No grade 5 TRAEs were observed. **Conclusions:** GEMOX plus tislelizumab and donafenib as a first line treatment option for advanced BTC patients shows favorable efficacy and tolerability. Clinical trial information: NCT05668884. Research Sponsor: Zelgen.

Additional health-related quality of life (HRQoL) analysis from DESTINY-Gastric04 (DG-04), a randomized phase 3 study of trastuzumab deruxtecan (T-DXd) vs ramucirumab (RAM) + paclitaxel (PTX) in patients (pts) with human epidermal growth factor receptor 2–positive (HER2+) unresectable/metastatic gastric cancer (GC)/gastroesophageal junction adenocarcinoma (GEJA). First Author: Kohei Shitara, National Cancer Center Hospital East, Kashiwa, Japan

Background: In DG-04 (NCT04704934), a statistically significant and clinically meaningful improvement in overall survival was seen with T-DXd vs RAM + PTX in pts with HER2+ unresectable/metastatic GC/GEJA in the second-line setting. Patient-reported HRQoL was also maintained with T-DXd. We report additional HRQoL results from DG-04. **Methods:** Pts with unresectable/metastatic GC/GEJA who were HER2+ (IHC 3+, IHC 2+/ISH+) by local or central testing received T-DXd 6.4 mg/kg or RAM + PTX. Patient-reported outcomes were assessed at prespecified time points using the Functional Assessment of Cancer Therapy-Gastric (FACT-Ga) scale and the EuroQol 5-dimension, 5-level (EQ-5D-5L) visual analog scale (VAS). Time to first deterioration (TTFD) and mean change from baseline (CFB) were assessed. Mixed model for repeated measures (MMRM) was used to analyze CFB of the FACT-Ga scale. **Results:** At data cutoff (October 24, 2024), median TTFD favored T-DXd (n = 246) vs RAM + PTX (n = 248) for the EQ-5D-5L VAS (3.5 vs 3.0 mo; hazard ratio [HR], 0.79; nominal P = 0.063), FACT-General (G) total score (3.5 vs 2.8 mo; HR, 0.74; nominal P = 0.015), and FACT-Ga emotional well-being (EWB; 5.1 vs 3.7 mo; HR, 0.74; nominal P = 0.026) and social well-being (SWB; 3.8 vs 2.5 mo; HR, 0.71; nominal P = 0.006) subscales. Additional TTFD results, including TTFD in gastric cancer subscale (GaCS) and physical well-being (PWB), are in the Table. Mean CFB scores remained stable in all FACT-Ga subscales, with no clinically meaningful changes associated with T-DXd. MMRM analysis of CFB results favored T-DXd vs RAM + PTX for the FACT-G total score (nominal P = 0.023), and the FACT-Ga functional well-being (FWB; nominal P = 0.045) and SWB (nominal P = 0.004) subscales. **Conclusions:** These findings support patient-reported HRQoL was maintained with T-DXd in pts with HER2+ unresectable/metastatic GC/GEJA. TTFD was not negatively impacted with T-DXd; mean CFB in all FACT-Ga subscales showed pt symptoms and functioning remained stable, with some subscales favoring T-DXd vs RAM + PTX. Clinical trial information: NCT04704934. Research Sponsor: Daiichi Sankyo, Inc.

Bortezomib plus gemcitabine-cisplatin versus gemcitabine-cisplatin as first-line treatment for advanced biliary tract cancers: A randomized phase II clinical trial with exploratory analysis of PTEN status. First Author: Hui Wang, Eastern Hepatobiliary Surgery Hospital, Shanghai, Naval Medical University, Shanghai, China

Background: Biliary tract cancers (BTCs) are aggressive malignancies with limited treatment and poor prognosis, including intrahepatic cholangiocarcinoma (iCCA), extrahepatic cholangiocarcinoma (perihilar and distal), gallbladder cancer and ampullary cancer. Our previous research indicated that bortezomib is a promising treatment option as proteasome inhibitor in PTEN-loss iCCA patients (Clin Transl Med. 2024 May;14(5): e1675). In this randomized phase II clinical trial, we expanded the indication to BTCs and explored clinical benefit and safety of bortezomib plus gemcitabine-cisplatin (GPB) compared with gemcitabine-cisplatin (G based) as first line treatment for advanced BTCs and further evaluated the potential predictive value of PTEN status. **Methods:** Between September 1, 2020, and December 31,2023, a total of 105 patients were screened. 59 patients were enrolled. The 59 patients were randomly assigned to either GPB group (n = 32) or G based group (n=27). PTEN status was not known at the time of randomization. PTEN immunohistochemical staining was subsequently performed in all patients identifying 18 patients (30.5%) with PTEN loss (PTEN=0) and 41 patients (69.5%) with PTEN expression (PTEN=1). The GPB regimen consisted of gemcitabine 1000 mg/m^2 day 1,8, cisplatin 75 mg/m^2 day 1, 8, plus bortezomib 1.3 mg/m^2 day 1, 4, 8, and 11 of a 21-day cycle. The G based group received gemcitabine based regimens including G-cisplatin (GP), G-Oxaliplatin (GMOX) or G-S-1 (GS). The primary endpoint was mediate progress-free survive (mPFS) according to RECIST v 1.1. Statistical analyses were performed using SPSS. The last follow-up date was July 25, 2025. **Results:** With a median follow-up of 31.8 months (95% CI, 21.3–42.3), the mPFS was 5.49 months in the GPB group and in 5.95 months in the G-based group, with no significant statistically significant difference (HR, 0.86; 95% CI, 0.50–1.47; P = 0.59). The median overall survival (OS) was 16.23 months with GPB and 15.01 months with G-based group (HR, 0.88;95% CI, 0.47–1.67; P = 0.70). Biomarker analyses showed that within the GPB group, patients with PTEN loss had significantly longer PFS than those with PTEN expression (9.26 vs. 3.35 months; HR, 0.64; 95% CI, 0.42–0.96; P = 0.03). Among PTEN=0 patients, GPB was associated with improved mPFS compared with G-based (9.26 vs. 3.59 months; HR, 0.25; 95% CI, 0.08–0.78; P = 0.01). Grade ≥3 CTCAE AEs were mainly hematologic, with thrombocytopenia most common (50.0% vs 14.8%). **Conclusions:** Although no significant survival benefit was observed in the overall GPB group, a clinically meaningful improvement in mPFS was identified in the PTEN-loss subgroup. PTEN status may serve as a promising biomarker for identifying patients more likely to benefit from GPB therapy, warranting further prospective validation. Clinical trial information: ChiCTR2000035916. Research Sponsor: the Clinical Research Plan of Shanghai Hospital Development Center (SHDC2020CR2011A).

Neoadjuvant radiotherapy combined with lenvatinib and sintilimab in patients with resectable hepatocellular carcinoma with portal vein tumor thrombus: An open-label, single-arm, multicenter, prospective phase I clinical trial. First Author: Bin Shu, Hepatopancereatobiliary Center, Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Beijing, China

Background: Surgical resection remains the potentially curative treatment for resectable hepatocellular carcinoma (HCC) with portal vein tumor thrombus (PVTT) in selected patients, but recurrence remains a major challenge. Neoadjuvant therapies have been proposed to reduce tumor burden and the risk of recurrence. This trial aimed to evaluate the safety and efficacy of neoadjuvant RT combined with lenvatinib and sintilimab followed by resection in resectable HCC patients with PVTT. **Methods:** This open-label, single-arm, multicenter, prospective phase I trial enrolled patients with resectable hepatocellular carcinoma classified as Barcelona Clinic Liver Cancer stage C without extrahepatic metastasis at 2 hospitals in China. Patients received RT (300cGy ×10 fractions) targeting intrahepatic lesions and PVTT, concurrent with two cycles of lenvatinib and sintilimab, followed by surgery 8 weeks post-RT and post-operative adjuvant therapy with lenvatinib and sintilimab for 1 year. Safety, pathological response, and feasibility were assessed. This trial is registered with ClinicalTrials.gov (NCT05225116). **Results:** From October 2022 to January 2026, 17 patients (VP2:5, VP3: 11, VP4:1) were enrolled, 14 patients had completed neoadjuvant therapy, 12 patients had received surgeries (R0 rate: 100%, 10/10), while 1 patient had disease progression, 1 patient postponed surgery due to abnormal liver function. Preoperative imaging (mRECIST criteria) showed stable disease (SD), partial response (PR), and complete response (CR) rates of 16.7%, 75.0%, and 8.3.0% for primary lesions, and 0%, 58.3%, and 41.7% for PVTT. Postoperative pathological complete response (pCR) rates were 25.0% for primary lesions and 75.0% for PVTT. Concordance between imaging and pathology was 66.7% for primary lesions and 50.0% for PVTT. The median recurrence-free survival (mRFS) was 17 months and median overall survival (mOS) was 27 months. No Grade 3 or worse treatment-related adverse events occurred. **Conclusions:** Neoadjuvant radiotherapy combined with lenvatinib and sintilimab can bring a high tumor response rate in patients with resectable hepatocellular carcinoma with portal vein tumor thrombus with a favorable safety profiles. PVTT demonstrates higher response rate than primary HCC lesions. Discrepancies between imaging and pathological responses highlight the need for improved predictive biomarkers. These interim results support further investigation of this approach in larger cohorts. Clinical trial information: NCT05225116. Research Sponsor: None.

QL1706 (PD-1/CTLA-4 bispecific antibody) plus bevacizumab specific for patients with hepatocellular carcinoma combined with lung metastasis: A secondary analysis of a prospective, single-arm, phase Ib/II study. First Author: Kunlin Xie, Department of General Surgery/Liver Transplant Center, West China Hospital, Sichuan University, Chengdu, China

Background: Hepatocellular carcinoma (HCC) with lung metastasis carries a dismal prognosis, and effective systemic treatments remain limited. Bispecific antibodies targeting multiple immune checkpoints have emerged as promising therapeutic strategies. This study assessed the efficacy and safety of QL1706, a PD-1/CTLA-4 bispecific antibody, in combination with bevacizumab in patients with HCC and lung metastases. **Methods:** This was a secondary analysis of a multicenter, phase Ib/II clinical trial. Eligible patients with unresectable, advanced HCC and confirmed lung metastases received QL1706 (5.0 or 7.5 mg/kg, cohort A) or QL1604 (PD-1 antibody, 200 mg, cohort B) plus bevacizumab every three weeks until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) per RECIST v1.1. Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** In cohort A, 15 patients were included in this analysis. At a median follow-up of 19.2 months, the ORR was 53.3% (95% CI, 26.6–78.7) and the DCR was 73.3% (95% CI, 44.9–92.2). Median PFS was 9.9 months (IQR, 1.6–NE), with a 1-year PFS rate of 46.7%, and the 2-year OS was 66.7%. Among the 7 patients with measurable lung target lesions, the ORR was 71.4% (95% CI, 29.0–96.3), including 2 complete responses. In cohort B, 5 patients were included, with a median follow-up of 23.7 months. The ORR was 20.0% (95% CI, 0.5–71.6) and the DCR was 60.0% (95% CI, 14.7–94.7). Treatment-related adverse events occurred in 93.3% of patients in cohort A and 100.0% in cohort B, with grade ≥3 TRAEs observed in 53.3% and 40.0% of patients, respectively. Most adverse events were manageable, and no treatment-related deaths were reported. **Conclusions:** QL1706 plus bevacizumab demonstrated promising antitumor activity and a manageable safety profile in patients with HCC and lung metastases. The high response rate observed in lung lesions highlights the potential of intensified immunotherapy combined with anti-VEGF therapy for this subgroup, warranting further validation in phase III trials. Clinical trial information: NCT05603039. Research Sponsor: Qilu Pharmaceutical Co., Ltd.

Hepatic arterial infusion chemotherapy plus either toripalimab or sorafenib as first-line therapy for non–high-risk, locally advanced hepatocellular carcinoma: A non-comparative, randomized phase 2 trial. First Author: Ming Shi, Department of Liver Surgery, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China

Background: A combination of locoregional therapy such as hepatic arterial infusion chemotherapy (HAIC) with anti-angiogenic agents and immune checkpoint inhibitors (ICIs), has demonstrated significant antitumor activity in advanced hepatocellular carcinoma (HCC), while inevitably increasing the incidence of adverse events (AEs). Given the clinical rationale for exploring treatment de-escalation in non-high-risk, locally advanced HCC, this study was designed to provide prospective evidence for the combination of HAIC and toripalimab, which had suggested encouraging antitumor activity and safety previously. **Methods:** This single-center, non-comparative, randomized phase II study (NCT04135690) recruited locally advanced HCC participants without high-risk features (Vp4, and/or bile duct invasion and/or tumor occupancy of 50% of the liver). Participants were randomly assigned at a 1:1 ratio to receive FOLFOX-HAIC plus either toripalimab (240mg intravenously, TorHAIC) or sorafenib (400mg orally twice daily, SoraHAIC) per 3 weeks. The primary endpoint was the progression-free survival (PFS) rate at 6 months. **Results:** From February 4, 2020, to December 17, 2021, 72 participants were randomly assigned to receive TorHAIC (n = 36) or SoraHAIC (n = 36). The mean tumor diameter was 9.9 cm. Vp1-2 and Vp3 portal vein tumor thrombosis were present in 46 (63.9%) and 26 (36.1%) participants, respectively. The 6-month PFS rate was 63.9% in the TorHAIC group and 61.1% in the SoraHAIC group. After a median follow-up of 45.2 months, the median overall survival was 20.9 months in the TorHAIC group and 16.4 months in the SoraHAIC group, while the median PFS was 9.1 and 7.2 months, respectively. The objective response rate per RECIST v1.1 was 52.8% (n = 19) in the TorHAIC group, whereas 47.2% (n = 17) in the SorHAIC group. The median duration of response was 9.8 months in the TorHAIC group and 6.8 months in the SorHAIC group. There were 12 participants (33.3%) who developed grade 3-4 AEs in the TorHAIC group and 16 participants (44.4%) in the SoraHAIC group. Serious AEs were reported in two participants in the TorHAIC group (laryngeal edema due to oxaliplatin allergy and thrombocytopenia) and five participants in the SoraHAIC group (impaired myeloid function [n = 3], renal impairment, and upper gastrointestinal bleeding). **Conclusions:** Our study suggested that the TorHAIC regimen had a favorable safety and efficacy profile in patients with non-high-risk, locally advanced HCC. However, these findings warrant validation in a phase III trial. Clinical trial information: NCT04135690. Research Sponsor: None.

Association of asynchronous, time-flexible digital multidisciplinary care with overall survival in advanced biliary tract cancer treated with immune checkpoint inhibitors. First Author: Binhe Tian, Peking Union Medical College Hospital, Beijing, China

Background: Delayed recognition and fragmented management of immune-related adverse events (irAEs) can trigger unnecessary interruption/discontinuation of immune checkpoint inhibitors (ICIs) and compromise real-world outcomes. We built an asynchronous, message-based multidisciplinary care system embedded in a widely used instant messaging platform to support longitudinal management for advanced biliary tract cancer (BTC) on ICIs, and assessed outcome changes from exploratory to protocolized implementation beyond secular trends. **Methods:** Single-center retrospective cohort of 546 adults with unresectable locally advanced/metastatic BTC receiving ≥1 ICI dose (Jan 2019–Jan 2024). All patients entered a clinician-moderated closed digital care group with structured triage and multidisciplinary coordination. By ICI start date: WGMS-E (before Jan 1, 2021) vs WGMS-P (on/after Jan 1, 2021). Primary endpoint: overall survival (OS). Secondary: progression-free survival (PFS), irAE recognition/management, and ICI rechallenge. Inverse probability of treatment weighting (IPTW) balanced baseline covariates. Interrupted time-series (ITS) analysis disentangled intervention effect from secular improvements in care. **Results:** Median follow-up 29.1 months; median OS overall 15.0 months. OS improved in WGMS-P vs WGMS-E (21.3 vs 12.4 months; log-rank $P < 0.0001$). IPTW-weighted Cox: WGMS-P associated with lower mortality (HR 0.55; 95% CI 0.43–0.69; $P < 0.001$) and higher 1-/2-year survival (~18%/~19% absolute). PFS also favored WGMS-P (HR 0.72; 95% CI 0.59–0.89; P = 0.0019). Overall irAE incidence was similar, but first irAE recognition occurred earlier in WGMS-P (restricted mean difference −1.68 months within 12 months). Permanent ICI discontinuation due to irAEs decreased (11% vs 22%), while rechallenge increased (10% vs 4%) without higher recurrent irAEs. ITS showed reversal of an increasing pre-intervention mortality trend to a decreasing post-intervention trend. **Conclusions:** A protocolized, asynchronous, message-based multidisciplinary care system integrated into routine oncology workflows was associated with improved survival among patients with advanced BTC treated with ICIs. By enabling earlier irAE recognition, reducing unnecessary permanent discontinuation, and facilitating safer rechallenge, this low-cost digital intervention may represent a scalable strategy to optimize real-world immunotherapy outcomes beyond secular advances in cancer care. These findings suggest that small, low-cost organizational changes in care delivery may translate into disproportionately large survival gains. Impact of ACE inhibitors (ACEi) and angiotensin receptor blockers (ARB) on outcomes in hepatocellular carcinoma treated with atezolizumab–bevacizumab. First Author: Costanza Winchler, Oncology Unit, Careggi University Hospital, University of Florence, Florence, Italy

Background: Immune checkpoint inhibitor–based combinations (ICIs), including atezolizumab–bevacizumab (AB), have dramatically changed the therapeutic landscape of unresectable hepatocellular carcinoma (HCC), improving survival and response rates of patients, although outcomes remain heterogeneous. Concomitant medications may modulate immunotherapy efficacy through systemic and tumor microenvironment–mediated effects. Inhibition of the renin–angiotensin system (RAS) has been suggested to potentiate the effects of immunotherapy in various solid tumors by acting on angiogenesis, fibrosis, and immune modulation. However, the clinical impact of RAS inhibition in HCC patients receiving ICIs remains controversial, with retrospective studies suggesting possible improved outcomes. **Methods:** Patients with unresectable HCC treated from 2023 to 2025 with AB in Italy were included in this retrospective multicenter analysis from the ARTE database. Patients receiving concomitant ACEi/ARB at AB initiation were compared with non-exposed individuals. OS and PFS were estimated by Kaplan–Meier method and analyzed using Cox proportional hazards models. ORR and DCR were analyzed using logistic regression. To address baseline imbalances, a propensity score adjustment for potentially confounding characteristics (age, ECOG PS, viral etiology, alcoholic liver disease, cirrhosis, diabetes, obesity, cardiovascular events, decompensated cirrhosis, ALBI score, vascular/biliary invasion, previous locoregional treatments, metastatic disease and alpha-fetoprotein levels) was performed. **Results:** A total of 538 patients were included in our analysis, of whom 36% were receiving ACE-i/ARBs and 64% were not. ACEi/ARB use was associated with worse OS (HR 1.23; 95% CI: 0.97-1.57, p = 0.092), and a trend toward lower DCR (OR 0.63, 95% CI 0.39–1.02; p = 0.06). No significant associations were observed for PFS or ORR. After propensity score adjustment to balance baseline confounders, the magnitude of the OS difference was attenuated: median OS was 17.0 months in ACEi/ARB users versus 19.4 months in non-users (HR 1.14 (95% CI: 0.86-1.51; p = 0.358)), suggesting that the unadjusted signal was partly driven by baseline imbalance. **Conclusions:** In this large multicentric cohort of HCC patients treated with AB, concomitant ACEi/ARB therapy did not improve clinical outcomes and was possibly associated with a negative survival trend. Further studies will be needed to assess the potential effect of concomitant medications and RAS inhibitors on HCC, given their widespread use and the burden of comorbidities related to this specific tumor. Research Sponsor: None.

Envafolimab (KN035) plus gemcitabine and oxaliplatin (GEMOX) compared with GEMOX as first-line treatment for Chinese patients with advanced biliary tract cancer: A randomized, open-label, multi-center, phase III pivotal trial. First Author: Shukui Qin, School of Integrative Medicine, Nanjing University of Chinese Medicine, Nanjing, China

Background: China bears a high biliary tract cancer (BTC) burden, with cholangiocarcinoma rising incidence (> 6/100,000 *vs* 0.3–6/100,000 globally) and high mortality (> 4/100,000). Over 60% of BTC patients are diagnosed at advanced stage (stage III/IV), and nearly two-thirds are unresectable. GEMOX regimen is a widely recognized standard of care in China, favored for its reduced renal toxicity and better tolerability compared with GemCis. Envafolimab is the world's first subcutaneously (SC) injectable anti-PD-L1 monoclonal antibody approved by China's NMPA. We report the final analysis of this pivotal trial, the first global phase III study initiated to evaluate immunotherapy plus chemotherapy in this setting. **Methods:** In this multicenter, open-label, phase III study in China, eligible patients (pts) with previously untreated, unresectable locally advanced/metastatic BTC were randomized 1:1 to envafolimab (2.5 mg/kg SC weekly) + GEMOX (gemcitabine 1000 mg/m² d1, 8; oxaliplatin 85 mg/m² d1, Q3W) or GEMOX chemotherapy alone. Chemotherapy was limited to 6 cycles in both arms. Stratification factors: primary site, disease stage, prior therapy, and ECOG PS. Primary endpoint: OS. Secondary endpoints: PFS, ORR (RECIST v1.1 by BICR), and safety. **Results:** 472 pts were randomized; 462 treated (envafolimab+GEMOX n = 232; GEMOX n = 230). At the final analysis, the primary endpoint was met well. Envafolimab+GEMOX significantly improved OS *vs* GEMOX (HR 0.723; 95% CI 0.585–0.880; *P*= 0.0016). Median OS was 10.9 months *vs* 8.6 months; 36-mo OS rates were 12.5% *vs* 7.7%. OS benefit was observed across subgroups, notably in intrahepatic cholangiocarcinoma (HR 0.705) and metastatic disease (HR 0.704). Median PFS (BICR) was 4.8 *vs* 4.6 months (HR 0.899; 95% CI 0.713–1.132); notably, the gallbladder cancer subgroup showed more favorable PFS benefit (HR 0.628). ORR was 27.6% *vs* 20.9%. Grade 3–4 TEAEs occurred in 69.4% (combination) *vs* 56.1% (chemo). irAEs occurred in 20.7%. **Conclusions:** This study demonstrates that adding subcutaneously administered envafolimab to GEMOX significantly improves OS with a manageable safety profile in advanced BTC. Compared with other regimens, the combination showed robust efficacy with a low rate of irAEs. Those findings establish envafolimab, the world's first SC PD-L1 inhibitor, combined with GEMOX as a new, effective, and convenient standard of care for this population. Clinical trial information: NCT03478488. Research Sponsor: 3D Medicines (Sichuan) Co., Ltd.

Impact of HSPA6 on lenvatinib resistance in HCC via phase separation–mediated TXNRD1 stabilization and ferroptosis suppression. First Author: Yi Niu, State Key Laboratory of Oncology in South China, Sun Yat-Sen University Cancer Center, Department of Liver Surgery, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Lenvatinib is a first-line treatment for advanced hepatocellular carcinoma (HCC), but its efficacy is frequently limited by intrinsic and acquired resistance. The underlying molecular mechanisms remain incompletely understood, and strategies to overcome resistance are urgently needed. **Methods:** We integrated genome-wide CRISPR/Cas9 screening, transcriptomic profiling of lenvatinib-resistant HCC cells, and proteomic analysis of patient tumors to identify key mediators of resistance. **Results:** Heat shock protein family A (Hsp70) member 6 (HSPA6) emerged as a central driver of both intrinsic and acquired resistance, was consistently upregulated in resistant models, and was associated with poor response and reduced survival in lenvatinib-treated patients. Functional studies demonstrated that HSPA6 knockdown sensitized HCC cells and xenograft tumors to lenvatinib, whereas HSPA6 overexpression conferred resistance both *in vitro* and *in vivo*. Mechanistically, HSPA6 recruited the deubiquitinase ubiquitin-specific protease 9X (USP9X) to stabilize thioredoxin reductase 1 (TXNRD1), thereby suppressing lenvatinib-induced ferroptosis. Moreover, lenvatinib enhanced HSPA6 liquid–liquid phase separation (LLPS) through its intrinsically disordered region 1 (IDR1), facilitating the formation of HSPA6–USP9X–TXNRD1 condensates that reinforced TXNRD1 stability. Through structure-based virtual screening, we identified canagliflozin, an FDA-approved sodium–glucose cotransporter 2 (SGLT2) inhibitor, as a direct HSPA6 binder that disrupted this complex, restored ferroptosis sensitivity, and synergized with lenvatinib in preclinical models. **Conclusions:** Our study defines a novel HSPA6-driven resistance axis that integrates chaperone function, phase separation, and redox homeostasis to suppress ferroptosis in HCC. Targeting this axis with canagliflozin represents a promising therapeutic strategy to overcome lenvatinib resistance. Research Sponsor: None.

NALIRIFOX in combination with adebrelimab for advanced biliary tract cancer: A phase 2 NIOFA-01 clinical trial. First Author: Qing Zhu, West China Hospital, Sichuan University, Chengdu, Sichuan, China

Background: The NIOFA-01 trial was designed to evaluate the efficacy and safety of liposomal irinotecan combined with oxaliplatin, fluorouracil, and leucovorin (NALIRIFOX) plus adebrelimab as first-line treatment for patients with advanced biliary tract cancer (BTC) (ChiCTR2400089696). **Methods:** This single-arm, phase II study enrolled 27 patients with previously untreated, unresectable or metastatic BTC. Patients received NALIRIFOX (liposomal irinotecan 50 mg/m², oxaliplatin 60 mg/m², leucovorin 400 mg/m², and fluorouracil 2400 mg/m² administered as a continuous intravenous infusion over 46 hours), in combination with the PD-L1 inhibitor adebrelimab (1200 mg administered intravenously), every 2 weeks for up to 12 cycles. This was followed by adebrelimab maintenance therapy until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR). Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety. Additionally, patients were evaluated for tumor gene alterations and PD-L1 expression, and underwent plasma proteomic and serum cytokine profiling. **Results:** Between September 13, 2024 and January 12, 2026, 27 patients were enrolled, with a median follow-up of 13.8 months (range, 2.8-16.2). Among these patients, the ORR was 55.6% (95%CI, 35.3%-74.5%) and the DCR was 81.5% (95%CI, 61.9%-93.7%). Median PFS was 8.0 months (95% CI, 5.8-9.7), while median OS was not reached (6 months OS rate: 92.6%, 12 months OS rate: 77.8%). Treatment-related adverse events (TRAEs) occurred in 100% of patients, with grade ≥3 TRAEs observed in 55.6%. The most common TRAEs were neutropenia, leukopenia, anemia, and diarrhea. Immune-related adverse events were reported in 74.1% of patients, including hepatotoxicity, hypothyroidism, and cardiac events. Exploratory analyses suggested the ORR was observed to be higher in patients with a CPS score ≥5 compared to those with a score <5 (p = 0.043). Combined analysis of plasma proteomics and metabolomics revealed that in patients who did not respond to treatment, ATP5PD, CTNND2, GALK1, 6nPropyluracil, and 1(Methylsulfinyl) propyl propyl disulfide were significantly elevated, while MMP2 was significantly decreased. A machine learning-based efficacy prediction model was constructed, and ROC curves were generated using the aforementioned four proteins and two metabolites, respectively, with AUC values of 0.961 and 0.883. Additionally, we observed that serum IL2 was significantly elevated in patients who responded to treatment, while IL8 showed a dynamic decreasing trend during the treatment process. **Conclusions:** NALIRIFOX in combination with adebrelimab demonstrated promising antitumor activity and an acceptable safety profile as first-line treatment for patients with advanced BTC, warranting further validation. Clinical trial information: ChiCTR2400089696. Research Sponsor: None.

Three-month versus six-month duration of postoperative adjuvant therapy after R0 resection following conversion therapy in hepatocellular carcinoma patients achieving MPR or pCR: A prospective randomized study. First Author: Jia-Yi Wu, Fuzhou University Affiliated Provincial Hospital, Fuzhou, China

Background: Conversion therapy allows a subset of patients with initially unresectable hepatocellular carcinoma (uHCC) to achieve a deep pathological response, enabling curative resection. However, the optimal duration of postoperative adjuvant therapy remains unclear. This prospective randomized study compared recurrence-free survival (RFS) and overall survival (OS) between 3-month and 6-month durations of postoperative adjuvant therapy after R0 resection in patients achieving major pathological response (MPR; ≥90% tumor necrosis) or pathological complete response (pCR). **Methods:** This randomized controlled trial (ChiCTR2100051789) enrolled patients with uHCC who achieved a MPR or pCR following conversion therapy. Eligibility criteria included pathological confirmation of MPR or pCR after R0 resection. Eligible patients were randomized 1:1 to receive 3 months (Group 3M) or 6 months (Group 6M) of postoperative adjuvant therapy starting 1 month after surgery. The primary endpoint was RFS; secondary endpoints included OS and recurrence patterns. **Results:** Between January 15, 2022, and April 20, 2025, 58 patients were randomized (29 per group). Pathological evaluation confirmed MPR in 21 patients and pCR in 37 patients. After a median follow-up of 33.05 months, recurrence occurred in 8 patients. The 1-, 2-, and 3-year RFS rates were 89.3%, 89.3%, and 78.8% in Group 3M and 88.9%, 88.9%, and 88.9% in Group 6M (P = 0.592). Corresponding OS rates were 100%, 96.4%, and 96.4% versus 100%, 91.8%, and 91.8%, respectively (P = 0.451). **Conclusions:** In patients with uHCC who achieved a deep pathological response (MPR or pCR) after conversion therapy, a shorter duration of adjuvant therapy may be sufficient, with a 3-month course providing survival outcomes comparable to those of a 6-month course. Clinical trial information: ChiCTR2100051789. Research Sponsor: None.

4122 **Poster Session**

Final results of a phase II study of fluorouracil (FU), leucovorin (LV), and nanoliposomal irinotecan (nal-IRI) in previously treated biliary tract cancer (NAPOLI-2). First Author: Benjamin Adam Weinberg, Ruesch Center for the Cure of Gastrointestinal Cancers, Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC

Background: BTCs are rare and aggressive malignancies. The first-line standard of care regimen for advanced BTC (aBTC) is gemcitabine (GEM), cisplatin, and an immune checkpoint inhibitor. Although FOLFOX is a preferred second-line treatment, it is limited by neuropathy. Nal-IRI contains IRI free base in liposome nanoparticles, which shelter IRI from conversion to its active metabolite (SN-38) and increase intratumoral SN-38 compared with IRI alone. The NAPOLI-1 trial of FU/LV/nal-IRI vs. FU/LV in second-line advanced pancreatic adenocarcinoma showed an overall survival (OS) benefit. The NIFTY trial (South Korea) demonstrated median OS (mOS) benefit of FU/LV/nal-IRI over FU/LV in a second-line aBTC population (8.6 vs. 5.3 months [mo], HR 0.68, 95% CI 0.48-0.95); however, the NALIRICC trial (Germany) did not (6.9 vs. 8.2 mo, HR 1.08, 95% CI 0.68-1.72). We sought to characterize second-line FU/LV/nal-IRI efficacy in US patients (pts) with second-line aBTC. **Methods:** This was a single-arm, open-label, multicenter phase II study of pts with aBTC previously treated with GEM/platinum chemotherapy. Pts received nal-IRI 70 mg/m^2 IV over 90 minutes, LV 400 mg/m^2 IV over 30 minutes every 14 days, and FU 2400 mg/m^2 IV over 46 hours every 14 days. The primary objective was to determine progression-free survival rate at 4 mo (PFS_{4mo}) using RECIST v. 1.1 criteria. Median PFS reported for pts receiving second-line 5-FU doublet chemotherapy was 3 mo with a PFS of 30%. FU/LV/nal-IRI was of interest if it could increase the PFS_{4mo} to 50% or higher. Using a one-sided α of 0.05 and 80% power, 17 of 39 evaluable pts had to be progression-free at 4 mo to detect a difference in PFS_{4mo} between 30% and 50%. **Results:** Forty-eight pts were enrolled: median age 64.5 years; 69% women; 27% gallbladder primary; 54% intra- and 19% extrahepatic. Ten pts came off study due to toxicity without disease progression before 4 mo on study and were replaced to evaluate the PFS_{4mo} endpoint. Of 38 evaluable pts, 18 pts (PFS_{4mo} 47%) were alive and progression-free at 4 mo, meeting the primary endpoint. With a median follow-up of 7.1 mo, median time to disease progression or study discontinuation due to toxicity for all pts was 2.3 mo (95% CI 1.8-4.6, PFS_{4mo} 38%), and for pts evaluable for the primary endpoint, median PFS was 3.5 mo (95% CI 1.8-5.5). Five pts (10%) had PFS beyond 12 mo. mOS for all pts was 7.9 mo (95% CI 5.7-11.7). Of 41 evaluable pts, the response rate was 2% (1 PR), and the disease control rate was 54%. Adverse events (AEs) were consistent with known toxicities from the FU/LV/nal-IRI regimen. **Conclusions:** FU/LV/nal-IRI is an effective second-line regimen for aBTC in US pts. There was significant early toxicity as 21% of pts came off study due to AEs before 4 mo. Correlative studies, including longitudinal analyses of circulating tumor DNA using banked blood specimens, are planned (NCT04005339). Clinical trial information: NCT04005339. Research Sponsor: Ipsen.

A phase II study of bTAE-HAIC combined with lenvatinib and camrelizumab for patients with high tumor burden hepatocellular carcinoma: The TALEM-H trial. First Author: Xue Han, Sun Yat-sen University Cancer Center, Guangzhou, China; Department of Minimally Invasive Interventional Therapy, State Key Laboratory of Oncology in South China; Collaborative Innovation Center of Cancer Medicine, Guangzhou, China

Background: Patients with high tumor burden hepatocellular carcinoma (HCC) face a dismal prognosis. TALEM-H is a single-arm, prospective trial, aiming to evaluate the safety and preliminary effectiveness of transcatheter arterial embolization with blank microspheres (bTAE) plus hepatic artery infusion chemotherapy (HAIC) combined with lenvatinib and camrelizumab as first-line therapy for patients with high tumor burden HCC. **Methods:** Forty patients with huge HCC (defined as a single tumor $>$10 cm or multiple tumors $>$15 cm in diameter) received bTAE and FOLFOX-HAIC (Oxaliplatin 85mg/m2 2h + Calcium Levofolinate 400mg/m2 2h + Fluorouracil 2400mg/m2 46h) and lenvatinib (4-8mg) once daily plus camrelizumab (200mg) Q3W. The primary endpoint was objective response rate (ORR) according to mRECIST criteria. Secondary endpoints included progression-free survival (PFS), overall survival (OS) and treatment-related adverse events (TRAEs). **Results:** As of January 10, 2026, the median follow-up time was 10.7 months. The median maximum tumor diameter was 124mm (range: 77.5–262 mm) and the median sum of the diameters of the three largest tumors was 182 mm (range: 110–328.5 mm). The intrahepatic ORR was 95%, with 7 cases (17.9%) of intrahepatic complete response (CR) and 30 cases (76.9%) of intrahepatic partial response (PR). The 1-year and 2-year PFS rates were 48.7% and 37.6%, respectively (median PFS: 10.4 months; 95% CI: 8.6–15.1). Median OS has not yet been reached. Further, TRAEs of any grade occurred in 35 patients (87.5%) and no treatment-related deaths occurred. Grade 3 or higher TRAEs occurred in 12.5% of patients, commonly hypoalbuminemia (5%), immune-mediated pneumonitis (2.5%), and anemia (2.5%). **Conclusions:** bTAE-HAIC combined with lenvatinib plus camrelizumab represents a promising first-line treatment, offering an exceptional ORR and encouraging survival outcomes for HCC patients with a high tumor burden. Clinical trial information: NCT06061276. Research Sponsor: None.

Baseline characteristics.

Variable	All Patients (N = 40)
BCLC Stage C	32 (80%)
Extrahepatic Metastasis	18 (45%)
Tumor Number- Multiple (≥3)	28 (70%)
Largest Diameter (cm) >10 cm	35 (87.5%)
Sum of the diameters of the three largest tumors >20 cm	14 (35%)
Macrovascular Invasion	27 (67.5%)

Beyond fibroblast growth factor receptor 2 (FGFR2) fusions: Mutations and amplifications in intrahepatic cholangiocarcinoma. First Author: Felicity David, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: *FGFR2* alterations occur in 10-20% of iCCA. While FGFR-directed therapies are established for *FGFR2* fusions, the genomic landscape and therapeutic relevance of non-fusion FGFR2 alterations remain poorly defined. **Methods:** Comprehensive genomic profiling was performed on 9,661 iCCA cases negative for *FGFR2* rearrangements/fusions to identify *FGFR2* short-variant sequence mutations and amplifications (Non-*FGFR2* SV/AMP). Biomarkers included tumor mutational burden (TMB), microsatellite instability (MSI), homologous recombination deficiency deficiency signature (HRDsig), and PD-L1 expression (TPS). Genomic features were compared with *FGFR2*-wild-type (*FGFR2*wt) iCCA. Clinical outcomes were assessed in a single-center cohort treated with FGFR inhibitors. **Results:** Non-*FGFR2* SV/AMP alterations were identified in 324 cases (3.4%), consisting of SV (92.8%), AMP (6.1%), or both (1.1%). Among short variants, 66.0% localized to the extracellular domain, 23.1% to the transmembrane domain, 7.69% to the kinase domain, and 3.21% to the cytoplasmic non-kinase domain. Compared with *FGFR2*wt tumors, Non-*FGFR2* SV/AMP iCCA occurred more frequently in females (57.7% vs 50.0%, p = 0.02) and showed similar age, genomic ancestry, trinucleotide signatures, MSI-high status (1.6% vs 1.8%), TMB $>$ 10 mt/Mb (2.2% vs 3.6%), PD-L1 positivity (18.8% vs 21.4%), and HRDsig positivity (4.6% vs 5.0%). Co-occurring actionable alterations (*IDH1*, *ERBB2, BRAF*, *MTAP* loss) were less frequent in Non-FGFR2 SV/AMP tumors, while *BAP1*, *NF2* and *TSC1* alterations were enriched. Among 42 patients with non-fusion *FGFR2* alterations treated at a single center, 16 (38%) received FGFR-directed therapy including pemigatinib, futibatinib, tinengotinib, lirafrugatinib and derazantinib. The objective response rate was 25% (95% CI: 7.3-52.4). Best responses included partial response (25%), stable disease (50%), and progressive disease (25%), with a median duration of response of 5.4 (95% CI: 1.9-8.9) months. Median overall survival was significantly longer in patients receiving FGFR-targeted therapy compared with those who did not (28.4 months [95% CI, 23.8-33.0] vs 14.6 months [95% CI, 6.25-23.0]; p = 0.023). Recurrent *FGFR2* mutations involved N549K (kinase), C382R (transmembrane), and Y375C (extracellular) domains. **Conclusions:** Non-fusion *FGFR2* sequence mutations and amplifications define a distinct subset of iCCA with fewer alternative actionable drivers and sensitivity to FGFR-targeted therapy. These findings support consideration of FGFR inhibition beyond *FGFR2* fusions and highlight the need for refined patient selection strategies. Research Sponsor: None.

First-line tislelizumab plus chemoradiotherapy for patients with advanced biliary tract cancer: A prospective, biomolecular exploratory, phase II trial. First Author: Mingzhen Zhou, The Comprehensive Cancer Center, Nanjing Drum Tower Hospital & Group's Suqian Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China

Background: Advanced biliary tract cancer (BTC) characterized by a poor prognosis, and the combination of immunotherapy with conventional chemoradiotherapy offers a promising therapeutic approach. **Methods:** This phase II study evaluated the efficacy and safety of tislelizumab (an anti-PD-1 antibody) in combination with chemoradiotherapy as a first-line treatment for advanced BTC. The primary endpoints were objective response rate (ORR) and R0 resection rate, and the secondary endpoints included median progression-free survival (mPFS), median overall survival (mOS), and Disease Control Rate (DCR). Biomarker analyses assessed CA19-9 dynamics and immune cell subsets. **Results:** Among 28 patients, the ORR was 57% (16/28), with a conversion rate of 14% (4/28) and a 100% R0 resection rate (4/4). The median PFS was 14 months and the median OS was 19 months. The regimen exhibited a manageable safety profile, with grade 3 adverse events occurring in 21% (6/28) of patients (2 with drug-induced liver injury and 4 with myelosuppression). No grade 4 events were observed. Reduced CA19-9 levels were significantly correlated with improved OS (p = 0.022) and PFS (p = 0.002). Immunohistochemistry analysis revealed differential expression of CD4, CD103, and PD-1 between responders and non-responders. Notably, high expression of $CD103^+CD8^+$ tissue-resident memory T (TRM) cells and $CD103^+CD8^+PD\text{-}1^+$ TRM cells was associated with significantly improved OS. **Conclusions:** In conclusion, the combination of tislelizumab with chemoradiotherapy demonstrates promising efficacy and acceptable safety in advanced BTC, with $CD103^+CD8^+$ TRM cells identified as a potential predictive biomarker. Clinical trial information: ChiCTR2300070425. CXCL12$^+$ pericytes as drivers of lymphatic dissemination in pancreatic cancer: Integrated single-cell and spatial analysis. First Author: Xiangxu Wang, Department of Clinical Oncology, Xijing Hospital, The Fourth Military Medical University, Xi'an, China

Background: Pancreatic ductal adenocarcinoma (PDAC) exhibits poor prognosis largely due to early lymph node metastasis, yet the cellular and molecular mechanisms governing lymphatic dissemination remain incompletely understood. **Methods:** We integrated multi-omics approaches including single-cell RNA sequencing (scRNA-seq) of 19 PDAC samples, spatial transcriptomics of 6 specimens, bulk RNA sequencing of 174 cases, and multiplex immunofluorescence of 166 clinical samples stratified by lymph node metastasis status. Cell-cell communication analysis, trajectory inference, and functional validation were performed to elucidate pro-metastatic mechanisms. **Results:** Single-cell profiling of 145,283 cells revealed substantial cellular heterogeneity, with fibroblasts and pericytes serving as dominant signaling hubs within the tumor microenvironment. Lymph node metastasis-positive (pLNM) tumors exhibited enhanced stromal-epithelial crosstalk mediated by PTN and ANGPT pathways. We identified invasive epithelial subpopulations (Epi_MUC5AC_CD24 and Epi_NEAT1_MALAT1) significantly enriched in pLNM samples, characterized by activation of EMT and invasion-related programs. Critically, high-resolution subclustering uncovered a CXCL12-expressing pericyte subset (PCs_CXCL12) preferentially expanded in metastatic tumors. Multiplex immunofluorescence validation in 166 specimens demonstrated that CXCL12+ pericyte infiltration correlated with perineural invasion, lymph node metastasis, advanced TNM stage, and inferior survival outcomes. Multivariate analysis established CXCL12+ pericyte score as an independent prognostic factor for both disease-free and overall survival. Mechanistically, we identified MYC as the master transcriptional regulator driving CXCL12 secretion in pericytes. Functional studies revealed that MYC-driven pericyte-derived CXCL12 promoted PDAC cell proliferation, invasion, and EMT. Spatial transcriptomics demonstrated co-localization of MYC, CXCL12, and its receptor CXCR4 in perineural pericyte niches. Orthotopic xenograft models confirmed that pericyte-specific Myc depletion significantly reduced tumor growth, CXCL12+ pericyte density, and tumor-associated lymphangiogenesis. **Conclusions:** This study establishes the pericyte MYC-CXCL12 axis as a critical driver of PDAC lymphatic metastasis through promotion of tumor cell invasion, EMT, and lymphangiogenesis. CXCL12+ pericytes represent a novel prognostic biomarker and potential therapeutic target for preventing lymph node metastasis in PDAC patients. Research Sponsor: None.

Distribution and density of tertiary lymphoid structures as predictors of clinical outcomes and immunotherapy responses in gallbladder cancer. First Author: Rui Zhang, 1st Affiliated Hospital of Xi'an Jiaotong University, Xi'an, Shaanxi, China

Background: Gallbladder cancer (GBC) is an aggressive malignancy with limited treatments and is often immunologically "cold." Tertiary lymphoid structures (TLS) are key regulators of antitumor immunity, but their spatial heterogeneity and clinical impact in GBC remain unknown. This study explores how TLS distribution and maturation influence outcomes and immunotherapy response in GBC. **Methods:** We analyzed 99 GBC patients who underwent curative resection (2015–2020). H&E and multiplex immunohistochemistry(mIHC) identified TLS number, maturation, and spatial distribution. TLS were categorized into intratumoral (T) and peritumoral (P) regions. Novel TLS scores (T score, P score) were developed to quantify TLS abundance and correlate with overall survival (OS). Pre-treatment samples from anti-PD-1-treated advanced GBC patients were assessed for TLS association with immunotherapy response. Patient-derived xenograft (PDX) models were used to compare tumor progression and anti-PD-1 efficacy between TLS-high and TLS-low groups. **Results:** T score correlated with improved OS ($p < 0.001$), while P score negatively correlated with OS ($p < 0.001$). Intratumoral TLS contained more Fol-I/Fol-II structures; peritumoral TLS were predominantly Agg ($p < 0.001$). Responders to immunotherapy had higher intratumoral TLS scores (median 2.5 vs. 0.5, $p < 0.01$), TLS numbers (8.0 vs. 3.0/ROI, $p < 0.05$), and TLS area (29.0% vs. 12.0%, $p < 0.05$). Intratumoral TLS showed higher CD8$^+$ T cells, CD4$^+$ T cells, and Tfh cells (all $p < 0.05$), whereas peritumoral TLS were enriched in Tregs ($p < 0.01$). Higher T scores linked with increased CD8$^+$ T cells, Tfh cells, CD21$^+$CD23$^+$ FDC, and LAMP3$^+$ DCs, but decreased Tregs and M2 macrophages (all $p < 0.05$). An immune classification based on T/P scores stratified patients into four prognostic subgroups with distinct OS ($p < 0.001$). In PDX models, TLS-high tumors progressed slower ($p < 0.05$) and responded better to anti-PD-1 therapy($p < 0.01$). **Conclusions:** TLS spatial distribution in GBC exerts opposing prognostic effects: intratumoral TLS promote antitumor immunity, while peritumoral TLS may support tolerance. TLS-high tumors show greater sensitivity to immunotherapy. A TLS-based immune classification may guide personalized treatment. Research Sponsor: National Natural Science Foundation of China; 82503726.

Real-world outcomes of microsatellite instability-high (MSI-H)/mismatch repair deficient (dMMR) biliary tract cancers (BTC). First Author: Madhulika Eluri, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Immune checkpoint inhibitors have revolutionized the treatment of microsatellite instability–high (MSI-H) or mismatch repair–deficient (dMMR) cancers. MSI-H/dMMR represents a rare molecular subset (1%) within biliary tract cancers (BTC). The role of immunotherapy alone remains unknown. We investigated clinical features, treatment outcomes, and genomic characteristics of MSI-H/dMMR BTCs in two real world cohorts. **Methods:** Multicenter retrospective study of BTC patients with MSI-H/dMMR status by immunohistochemistry (IHC) and/or PCR. Patients were from two independent cohorts: MD Anderson Cancer Center (MDACC) and the RETUD registry of the Spanish Cooperative Group for Digestive Tumor Therapy (TTD) group. **Results:** 46 patients with MSI-H BTC were included in this study; with 21 from MDACC and 25 patients from TTD Cohort. Median age 46 years (95% CI38-80), (35 (76.1%) had intrahepatic cholangiocarcinoma 8 (17.4%) had extrahepatic cholangiocarcinoma and 3 (6.5%) had gallbladder cancer. Patient characteristics are summarized in Table 1. The median OS was 24.4 months (95% CI: 19.9, 40.6). The median follow-up time was 50.2 months (95% CI: 36.2, NA). Thirty-one (68.9%) patients received immunotherapy as part of their treatment course, and 14 (31.1%) did not. For first-line therapy (n=40), the median progression-free survival (PFS) for chemotherapy was 3.19 months (95% CI: 2.56-6.6) and for immunotherapy alone was not reached (95% CI: 8.25-NR, p=0.0006), while among those receiving second-line therapy (n=21), the median PFS for chemotherapy was 4.04 months (95% CI: 2.73-NR) and for immunotherapy alone was 9.69 months (95% CI: 4.43-NR, p=0.044). The median OS was 24.7 months (95% CI: 19.91, NA) in patients with IO, and 19.1 months (95% CI: 13.83, NA) without IO (log rank test p value = 0.085). **Conclusions:** MSI-H/dMMR BTC patients may derive limited benefit with frontline chemotherapy. Immune checkpoint inhibition may drive durable disease control, supporting early dMMR/MSI-H testing to optimize treatment. Research Sponsor: None.

A phase I/II study of CDX-1140, a CD40 agonist, in combination with capecitabine and oxaliplatin (CAPOX) and pembrolizumab in subjects with biliary tract carcinoma: Phase 1 results. First Author: Tim F. Greten, Thoracic and Gastrointestinal Malignancies Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Second line therapy shows limited efficacy in biliary tract carcinoma (BTC). We have demonstrated potent anti-tumor effects of anti-CD40/anti-PD1 plus chemotherapy in murine cholangiocarcinoma (Diggs et al. J Hepatol 2021 74:1145). CDX1140 is a human IgG2 activating anti-CD40 antibody. Based on these preclinical studies we conduct a phase I/II study testing the combination of CDX-1140 plus pembrolizumab (pem), capecitabine (cap) and oxaliplatin (ox) in BTC patients previously treated with at least one line of systemic therapy. Safety and tolerability were assessed in the phase I portion. **Methods:** Between Aug 2024 and Jun 2025 a total of 9 participants were enrolled into the Phase I portion of the trial. 1000 mg cap was given p.o. bid on days 1-14 plus 130 mg/m2 ox i.v. on day 1 of a 21-day treatment cycle. CDX1140 was dosed at 0.72 mg/kg dose level 1 (DL1) and 0.36 mg/kg (DL-1) i.v. on day 8 plus 200 mg pembrolizumab i.v on day 8. The DLT period was 35 days, starting on day 8 of cycle 1 after CDX-1140 administration. Enrolment into the phase II portion was started after the recommended dose of CDX-1140 had been determined. **Results:** We enrolled a total of 9 patients (pts) into the phase I portion. All patients had received at least one line of prior systemic chemotherapy including antiPD1/PD-L1. 2 out of the first 3 pts treated at DL1 developed a grade 3 thrombocytopenia and we reduced dosing to DL-1. 1 out of 6 pts treated at DL-1 developed a grade 3 thrombocytopenia and DL-1 was considered safe. Other treatment related grade 3/4 AEs were: lymphopenia, leukocytopenia, anemia, skin rash and hypotension. Most patients developed grade 1/2 arthralgia. At data cut-off (Dec/15/25) PFS for the nine patients was 7.3 months (range: 2.3 - 19.1 months). DCR was 56 % with 2 patients demonstrating a PR and 3 pts with SD. **Conclusions:** We have completed the phase I portion of our trial and demonstrate that CDX1140 plus pem, cap and ox is safe and tolerable in pts with BTC. No new and or unexpected toxicities were observed. We observed encouraging clinical responses. Patients will be enrolled to the phase II portion and updated results will be presented. Clinical trial information: NCT05849480. Research Sponsor: None.

Sequential bTAE-HAIC combined with lenvatinib and sintilimab for infiltrative hepatocellular carcinoma: A single-center perspective. First Author: Qunfang Zhou, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong Province, China

Background: Infiltrative hepatocellular carcinoma (HCC) is defined as a tumor with ill-defined border, no evidence of convex margination, and no typical enhancement pattern by imaging. This subtype of HCC is usually associated with poor prognosis and is frequently diagnosed at advanced stage. Blank-microsphere transcatheter arterial embolization (bTAE) and hepatic arterial infusion chemotherapy (HAIC) of oxaliplatin, 5-fluorouracil and leucovorin are effective and safe for HCC. This prospective study is to evaluate the safety and efficacy of bTAE-HAIC combined with Lenvatinib and Sintilimab for intermediate-advanced infiltrative HCC. **Methods:** This prospective phase II trial is a single-center, single-arm study designed to assess the efficacy and safety of TAE and HAIC, combined with sequential Lenvatinib and Sintilimab on infiltrative HCC. Patients with primary infiltrative HCC treated at our center between October 2023 and December 2024. The primary endpoint was objective response rate (ORR) according to mRECIST criteria. Secondary endpoints included overall survival (OS), progression-free survival (PFS), and treatment-related adverse events (AEs). **Results:** A total of 30 patients who met the criteria were enrolled in this study and received at least 2 courses of TAE-HAIC combined with Lenvatinib and Sintilimab treatment. The median follow-up time was 7.1 months, and 10 patients died during the period. 5 patients (16.7%) achieved complete response (CR) after sequent ablation or radiotherapy, 20 patients (66.7) were evaluated as PR. The overall ORR was 83.3%. The median OS was 16.0 months (95%CI: 5.6-26.5 months). The 3-month, 6-month and 12-month rates of OS were 93.3%, 83.0% and 60.2%. The median PFS was 9.5 months (95%CI: 4.9-14.1 months), and the PFS rates at 3-month, 6-months and 12-month were 95.7%, 68.1% and 20.4%, respectively. The median liver-specific PFS was 11.7 months (95%CI: 7.7-15.7 months). The overall incidence of treatment related AEs was 76.7% according to the CTCAE 5.0 criteria. The incidence of Grade 1-2 AEs was 73.3%, and only one patient experienced Grade 3 AE. 10 patients (33.3%) received dose reduction, 9 patients (30.0%) discontinued drug therapy. **Conclusions:** The preliminary results of current study indicates that the combination regimen is safe and effective, and the AEs and complications are controllable and tolerable. This study provides a reference for further phase III clinical research, and a novel treatment option for the infiltrative HCC. Clinical trial information: NCT06070636. Research Sponsor: None.

Hepatic arterial infusion chemotherapy plus lenvatinib and PD-1 inhibitors as first-line treatment for hepatocellular carcinoma with high tumor burden and portal vein tumor thrombus: A target trial emulation study (CHANCE 2416). First Author: Jiaxi Liu, The First Hospital of China Medical University, Department of Interventional Radiology, Shenyang, China

Background: Patients with advanced hepatocellular carcinoma (HCC) characterized by high tumor burden (beyond up-to-seven criteria) and portal vein tumor thrombus (PVTT) have a median overall survival (OS) of lower than 4 months without intervention. Global guidelines rely on Phase III trials that often under-represented this high-risk subgroup, creating a therapeutic gap. While systemic combinations are standard, they may lack the rapid cytoreductive potency required to prevent liver failure in this subgroup. We emulated a target trial to evaluate if adding hepatic arterial infusion chemotherapy (HAIC) to lenvatinib and PD-1 inhibitors (H+L+P) improves outcomes compared to lenvatinib and PD-1 inhibitors (L+P) alone. **Methods:** Using multicenter data from 22 centers in the Chinese Liver Cancer Clinical Study Alliance (CHANCE) registry, we compared first-line H+L+P (n = 127) vs. L+P (n = 117) in patients with advanced HCC (BCLC stage C without extrahepatic spread) and PVTT (Vp1-4). To minimize selection and immortal time biases, we employed stabilized inverse probability of treatment weighting (sIPTW) and a cloning-censoring-weighting framework. The primary endpoint was OS; secondary endpoints included progression-free survival (PFS), site-specific PFS, objective response rate (ORR), and safety. **Results:** Baseline covariates were well-balanced after weighting (SMD < 0.1). After sIPTW adjustment, H+L+P demonstrated a significant survival benefit: median OS was 25.6 months (95% CI: 22.0–33.7) vs. 15.9 months (95% CI: 12.6–21.3) for L+P (adjusted HR, 0.60; 95% CI: 0.43–0.82; p = 0.0015). Crucially, a favorable survival trend was preserved even in the high-risk Vp3-4 subgroup (HR 0.77). Median PFS (RECIST v1.1) was 13.0 vs. 6.8 months (adjusted HR, 0.58; p = 0.0002). H+L+P significantly delayed progression in intrahepatic lesions (median 14.8 vs. 7.8 months; p = 0.0006) and PVTT (median 24.9 vs. 15.5 months; p = 0.0183). Intrahepatic ORR (mRECIST) was 87.4% for H+L+P vs. 28.9% for L+P ($p < 0.0001$), with a PVTT response rate of 81.6% vs. 22.1% ($p < 0.0001$). Grade ≥3 adverse events (AEs) occurred in 37.0% of the H+L+P group vs. 9.4% in the L+P group. Common Grade ≥3 AEs in the H+L+P arm included abdominal pain (20.5%) and leukopenia (5.5%); no treatment-related deaths occurred in the H+L+P group. **Conclusions:** In this target trial emulation, adding HAIC to lenvatinib and PD-1 inhibitors significantly improved OS and PFS in patients with high-risk HCC and PVTT. The survival advantage was driven by rapid and profound locoregional control, particularly of the tumor thrombus, with a manageable safety profile. Clinical trial information: NCT06631326. Tinengotinib (TT-00420) in advanced/metastatic FGFR2-altered cholangiocarcinoma following prior chemotherapy and FGFR inhibitor treatment: Results from a phase II study (FIRST-08). First Author: Jun Zhou, Peking University Cancer Hospital & Institute, Beijing, China

Background: Subsequent treatment options for advanced cholangiocarcinoma (CCA) after failure of chemotherapy and FGFR inhibitors (FGFRi) are limited. Tinengotinib (TT-00420), a novel FGFRi, potently inhibited FGFR2 fusion/rearrangement and acquired resistant/FGFR2 kinase domain mutations. The FIRST-08 study is an open-label, multicenter Phase II study in Chinese patients (pts) with advanced/metastatic CCA (NCT06057571). **Methods:** Eligible pts with advanced/metastatic CCA harboring FGFR2 fusion or arrangement, who had failed prior chemotherapy and one FGFRi, received tinengotinib 10 mg orally once daily in 21-day cycles. The primary endpoint was objective response rate (ORR) per RECIST v1.1 by blinded independent central review (BICR). Secondary endpoints included progression free survival (PFS), disease control rate (DCR), duration of response (DoR), overall survival (OS), safety, PK and quality of life (QOL) per EORTC QLQ-C30. **Results:** As of June 27, 2025, 50 pts were enrolled (median age 56.5 years; 52.0% male; ECOG of 1: 44.0%). Median follow-up was 8.5 months. Forty percent had ≥ 3 prior systemic regimens, 66.0% had prior immunotherapy, and 42.0% had received other targeted therapies beyond FGFRi. The ORR by BICR was 28.0% (95%CI, 17.5~41.7) with 14 confirmed partial responses, and median DoR was 7.9 (5.6~ -) months. The disease control rate (DCR) was 82.0%. The median PFS was 5.7 (4.3~8.3) months. The median OS had not reached, with the 18 months survival rate 66.9% (47.3~80.6). Common Gr3/4 TRAEs (≥15%) included hypertension (42.0%), palmar-plantar erythrodysesthesia syndrome (16.0%), No Gr 5 TRAE was observed. 41 out of 50 pts had biomarker ctDNA samples collected at baseline, 82.9% pts had FGFR2 fusion and 48.8% had FGFR2 mutation (SNV). 28 pts had biomarker ctDNA samples collected at both baseline and C3D1. A significant decrease in maximum variant allele frequencies (MaxVAF) from baseline to C3D1 by a median relative VAF reduction of 83.7% ($p<0.0001$), indicating strong molecular response to tinengotinib. **Conclusions:** Tinengotinib demonstrated durable clinical anti-tumor activity and a manageable safety profile in heavily pretreated CCA pts with FGFR2 fusion/rearrangement following prior chemotherapy and FGFRi therapy. Clinical trial information: NCT06057571. Research Sponsor: TransThera Sciences (Nanjing), Inc.

Efficacy outcomes by BICR and investigator.

Correlation of immune remodeling linked to obesity with immunotherapy outcomes in cholangiocarcinoma: An externally validated international cohort study. First Author: Antonella Cammarota, Department of Biomedical Sciences, Humanitas University, Pieve Emanuele; Hepatobiliary Immunopathology Lab, IRCCS Humanitas Research Hospital, Rozzano, Milan, Italy

Background: Obesity is an established risk factor for cancer, yet paradoxically may be associated with improved responses to immune checkpoint inhibitors (ICIs). We investigated whether obesity defines a clinically and biologically distinct cholangiocarcinoma (CCA) subtype when treated with ICIs. **Methods:** Retrospective analysis of Body Mass Index (BMI)-stratified patients (pts) with CCA treated at a single US center (US cohort) and enrolled in a prospective multicenter Italian registry (Italian cohort). High BMI was defined per CDC criteria (overweight 25.0-29.9; obesity ≥30 kg/m²), with cohort-specific cutoffs for analysis (US ≥30; Italy ≥25). Tumor microenvironment (TME) was profiled with bulk RNA-seq and CODEX multiplex imaging and body composition radiomics with TotalSegmentator tool in the US cohort. Chi-square, Pearson correlation or Wilcoxon tests were used to test associations with BMI; overall survival (OS) was assessed with Kaplan-Meier and Cox models. **Results:** 989 pts were included (661 US; 328 Italy). In the US and Italian cohorts, median age was 62 and 65 years, 51% and 47% were female, and 28% and 43% were obese and overweight, respectively. Metabolic comorbidities included diabetes (US: 15%; Italy: 19%), hypertension (US: 48%; Italy: 45%), and hyperlipidemia (US: 32%; Italy: 15%). Higher subcutaneous-to-visceral fat ratio was associated with improved OS with chemotherapy-ICI (HR 0.89; 95% CI 0.79-0.99; p = 0.036). In both cohorts, patients with high BMI treated with chemotherapy-ICI had significantly longer OS compared with lower-BMI patients (US: 31.6 vs 19.2 months, p = 0.005; Italy: 21 vs 12 months, p = 0.025). In multivariable models (US cohort) both obesity (HR 0.35; 95% CI 0.23-0.52, $p < 0.0001$) and higher visceral-to-subcutaneous fat ratio (HR 1.79; 95% CI 1.04-3.07, p = 0.037) were independently associated with OS. Combined genomic profiling (n = 906) showed a lower prevalence of *KRAS* alterations in high-BMI pts (OR 0.56, p = 0.006). RNA-seq (n = 86; obese = 37, non-obese = 49) demonstrated enrichment of fibroblast-associated signatures (*αSMA, PDPN, collagen IV, vimentin*), upregulation of immune checkpoints (*PD-1, PD-L1, TIGIT, LAG-3, VISTA*), and higher *GATA3* and *IFN-γ* expression in obese pts (both $p < 0.05$). Multiplex CODEX analysis (n = 38; obese = 17, non-obese = 21) revealed an increased co-expression between *GATA3*, a regulator of T-cell dysfunction, and *granzyme B*, a cytotoxic T-cell marker (Pearson $\rho = 0.24$, $p < 0.05$), indicating increased abundance of *GATA3⁺granzyme B⁺* cells in obese pts. **Conclusions:** In CCA, obesity characterized by predominant subcutaneous adiposity is linked to improved outcomes with ICIs and to a biologically distinct TME enriched in dysfunctional cytotoxic T-cells that may be reinvigorated by checkpoint inhibition. BMI may represent a pragmatic biomarker warranting prospective validation. Research Sponsor: None.

Association of genomic and clinical factors with outcomes with front-line chemoimmunotherapy in patients with advanced biliary tract cancer. First Author: Orla Maeve Fitzpatrick, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Anti-PD1/L1 therapy plus gemcitabine/cisplatin is standard first-line therapy in advanced biliary tract cancer (BTC), yet outcomes remain heterogeneous and prognostic biomarkers are poorly defined. We aimed to identify genomic and clinical factors associated with outcomes in advanced BTC patients (pts) treated with first-line gemcitabine, cisplatin and durvalumab (GCD). **Methods:** All pts with advanced BTC treated with first-line GCD at Memorial Sloan Kettering who underwent pre-treatment tumor genomic profiling (NCT01775072) were included. The primary objective was to study the association between genomic and clinical features and investigator-assessed progression free survival (PFS); evaluation of overall survival (OS) was a secondary objective. Cox regression analyses evaluated associations with PFS/OS. A multivariable Cox PFS model used variables selected by LASSO-based stability selection and was stratified by tumor subtype. **Results:** 236 pts were eligible for analysis. Tumor subtypes included intrahepatic cholangiocarcinoma (CCA) (56%), gallbladder cancer (23%), extrahepatic CCA (16%), and BTCs not otherwise specified (5%). Common genomic alterations were *TP53* (36%), *ARID1A* (24%), *CDKN2A* (23%), *KRAS* (17%), *IDH1* (13%), *SMAD4* (12%), *MTAP* (11%) and *ERBB2* (7.6%). With a median follow up of 23 months (mo), median PFS for the cohort was 9.1 mo (95% CI 7.7–11.0). OS at 12 and 24 mo was 68% (95% CI: 62–74) and 45% (95% CI, 38–53), respectively. On univariable analysis, *KRAS* and *FGFR2* alterations were associated with shorter PFS (Table). *KRAS* alterations were also associated with an increased risk for all-cause mortality on univariable analysis (HR 1.81, 95% CI: 1.17–2.81, p=0.008). Median PFS and OS for the *KRAS*-altered group were 5.6 (95% CI: 3.6-7.8) and 11 (95% CI: 7.8-42) mo respectively, compared to 11 (95% CI: 8.1-12) and 21 (95% CI: 19-28) mo for *KRAS*-WT patients. On multivariable analysis, *KRAS* alterations and liver metastases were independently associated with shorter PFS; higher baseline albumin was protective (Table). **Conclusions:** Among pts with advanced BTC treated with front-line GCD, *KRAS* alterations were independently associated with poor PFS. These findings highlight the heterogeneity of benefit from GCD and support development of biomarker-informed strategies to refine patient selection and incorporation of KRAS-targeted strategies to improve outcomes in patients with *KRAS*-mutant BTCs. Research Sponsor: None.

Updated results of surufatinib combined with gemcitabine and cisplatin and immune checkpoint inhibitor (ICI) for unresectable locally advanced or metastatic intrahepatic cholangiocarcinoma. First Author: Zhong Jingtao, De-Department of Hepatobiliary Surgery, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China

Background: Advanced metastatic intrahepatic cholangiocarcinoma (ICC) was characterized by poor survival and limited therapeutic options. Surufatinib, a selective tyrosine kinase inhibitor targeting VEGFR 1, 2, and 3, FGFR1, and CSF-1R, provides dual anti-tumor action via anti-angiogenesis and tumor microenvironment regulation. Surufatinib combined with immunotherapy and chemotherapy may enhances anti-cancer effects for advanced metastatic ICC. This study evaluates the effectiveness and safety of surufatinib combined with gemcitabine, cisplatin, and immune checkpoint inhibitor (ICI) as the first-line treatment for patients with unresectable locally advanced or metastatic intrahepatic cholangiocarcinoma. **Methods:** This is an open-label, single-arm, single-center trial. Eligible patients who were 18 -75 years old with histologically confirmed unresectable locally advanced or metastatic ICC were enrolled. Pts received surufatinib (250mg, orally, once daily), ICI (Zimberelimab or Toripalimab, 240mg, intravenous infusion, d1, q3w), and chemotherapy (gemcitabine 1000mg/m^2 intravenous infusion, 30min, d1, d8, q3w; cisplatin 25mg/m^2 intravenous infusion, 2h, d1, d8, q3w) until disease progression, death, surgery, intolerable toxicity, or withdrawal of consent. The primary endpoint was objective response rate (ORR). Secondary endpoints included progression-free survival (PFS), disease control rate (DCR), overall survival (OS), conversion to surgical resection rate, pathological complete response rate (pCR), and safety. **Results:** By January 20, 2026, 20 pts were enrolled with median age 60 years (range: 43-70), male 50%, 100% ECOG PS 0-1, 95% stage IV. 20 pts were efficacy evaluable, 5% (1/20) pts achieved complete response (CR), 50% (10/20) pts achieved partial response (PR), 35% (7/20) pts achieved stable disease (SD). The confirmed ORR was 55%, DCR was 90%. The median PFS was 7.7m (95%CI: 6.3-11.3 months), and the median OS was 17.8m (95%CI: 16.1-21.8 months). The most common TEAEs of all grades were hypertension (40%), edema (15%) and vomiting (10%), 1 patient was Immune-related pneumonia occurred. No grade $\geq$ 3 TEAEs or new safety signals occurred. **Conclusions:** Surufatinib plus gemcitabine and cisplatin combined with immune checkpoint inhibitor, the chemotherapy regimen as the standard treatment in combination with targeted and immunotherapy showed preliminary anti-tumor activity and manageable toxicity for the 1L treatment of ICC, providing an additional treatment option for pts with ICC. This study has been completed and the paper has been prepared for submission, the final results details will be published after the conference. Clinical trial information: ChiCTR2400085526. Research Sponsor: None.

Tracking genomic evolution in *ERBB2*-altered biliary tract cancer through longitudinal tumor profiling. First Author: Orla Maeve Fitzpatrick, Memorial Sloan Kettering Cancer Center, New York, NY

Background: HER2, encoded by *ERBB2* (HER2), is overexpressed and clinically actionable in a subset of patients with biliary tract cancers (BTC). Zanidatamab and trastuzumab deruxtecan are now approved for patients with HER2 overexpressed tumors, though all patients ultimately progress on treatment and acquired resistance mechanisms are poorly defined. We aimed to characterize the genomic evolution in patients with *ERBB2* altered advanced BTC via serial tumor and cfDNA sampling during systemic therapy. **Methods:** Patients with *ERBB2* altered BTC were extracted of Memorial Sloan Kettering Cancer Center (MSK)'s prospectively maintained institutional genomic profiling protocol (NCT01775072). Eligibility required $\geq$2 molecular profiles obtained during systemic therapy. Tumor sequencing was performed using MSK-IMPACT (tissue-based NGS) and/or MSK-ACCESS (ctDNA NGS). Paired samples could include tissue and/or ctDNA. Clinical data were annotated, and longitudinal molecular profiles were analysed to assess temporal changes in *ERBB2* status. **Results:** Among 1628 patients with BTC in the institutional database, 122 (7.5%) had *ERBB2* altered tumors. Of these, 26 patients had $\geq$2 molecular samples available for longitudinal analysis. Five were excluded due to incomplete clinical and/or molecular data, leaving 21 eligible patients [Median age at diagnosis, 63 years (range 38–76), gallbladder cancer (n = 12, 57%), intrahepatic cholangiocarcinoma (n = 6, 29%), and extrahepatic cholangiocarcinoma (n = 3, 14%)]. At baseline, *ERBB2* alteration patterns included *ERBB2* amplification in 15 patients (71.4%), single nucleotide variants (SNV) in 2 patients (9.5%), and concurrent amplification and SNVs in 3 patients (14.3%). The most common co-occurring alterations involved *TP53* (67%), *SMAD4* (19%), *CDKN2A* (19%), and *SMAD4* (19%). Over the course of systemic treatment [Median number of treatment lines, 3.5 (range 1-6), 71% patients received HER2 directed therapy (n = 15) at any line], loss of *ERBB2* amplification at last available molecular sampling was observed in 7 patients (46%) and gain in 1 patient. Longitudinal profiling also demonstrated acquisition of additional alterations in receptor tyrosine kinase (RTK) pathways, including *MAPK* genes in 19% patients and *MET* alterations in 4.7%. Among the 15 patients who received HER2-directed therapy, *MAPK* alterations were observed in 4 (25%) and *MET* alterations in 1 (6%) at progression. **Conclusions:** *ERBB2* alterations in BTC evolve over time with frequent loss of amplification and emergence of RTK pathway alterations during systemic therapy. Acknowledging limitations of small sample size as well utilization of both cfDNA and tumor profiling, these findings highlight the genomic heterogeneity of *ERBB2* altered BTC and support the potential value of longitudinal profiling to better understand mechanisms of resistance and help inform treatment sequencing. Research Sponsor: None.

Homologous recombination signature (HRDsig) in clinically advanced gallbladder adenocarcinoma (CAGAC): A genomic landscape study. First Author: Myungwoo Nam, SUNY Upstate Medical University, Syracuse, NY

Background: CAGAC is an aggressive malignancy with poor prognosis where chemotherapy and immunotherapy provide a limited benefit. There have been clinical trials investigating the benefit of PARP inhibitors in biliary tract cancers. HRDsig positivity in other types of cancer have shown to predict sensitivity to PARP inhibitors. We explored the genomic characteristics of CAGAC patients according to the HRDsig status using a large real-world genomic dataset. **Methods:** Comprehensive genomic profiling was performed on 2,423 cases of CAGAC to assess all types of genomic alterations (GA), including base substitutions, short insertions and deletions, copy number changes, rearrangements, and fusions. Microsatellite instability (MSI) status, tumor mutational burden (TMB), genomic ancestry, and trinucleotide signatures were determined from the sequencing data. PD-L1 was determined with the DAKO 22C3 IHC assay. HRDsig status was determined by measuring large scale copy number changes and DNA repair errors. Patients were grouped into HRDsig positive (HRDsig+) and negative (HRDsig-) based on results. Genes with GA $\geq$5% in either population were included in the analysis. **Results:** Among 2,423 total cases, 152 (6.3%) were HRDsig+. Between MRDsig+ and MRDsig-, there was no significant difference in gender (female 76.3% vs 69.1%, p = 0.061), age (median 66.5 vs 68.0 yrs; p = 0.065), genomic ancestry (EUR 67.6% vs 63.7%, p = 1.0), MSI-H status (0.0% vs 1.3%, p = 0.468), PD-L1 expression (Low 34.0% vs 23.4%, p = 0.529. High 1.9% vs 5.4%, p = 0.946). Median GA per tumor was the same between groups (median 5 vs 5, p = 0.723), but the proportion of TMB$\geq$10 mut/Mbp were higher in HRDsig+ (12.5% vs 4.7%, p = 0.001). HRDsig+ had more frequent alterations in BRCA1 (9.2% vs 1.4%, p $<$ 0.001), BRCA2 (21.7% vs 1.9%; p $<$ 0.001), PALB2 (11.2% vs 0.4%; p $<$ 0.001), NF1 (9.9% vs 4.4%; p = 0.018), PIK3R1 (5.9% vs 2.5%; p = 0.05), and PTEN (11.8% vs 5.3%; p = 0.015). HRDsig- had more frequent alterations in ERBB2 (5.9% vs 19.0%, p $<$ 0.001), KRAS (5.9% vs 14.9%, p = 0.007), and MDM2 (3.3% vs 9.4%, p = 0.024). **Conclusions:** HRDsig positivity comprised approximately 6% of all CAGAC cases. HRDsig+ were associated with a higher proportion of mutations related to homologous recombination repair (HRR) genes and mTOR pathway, whereas HRDsig- demonstrated a higher proportion of common driver mutations such as ERBB2 and KRAS. Notably, there were cases with discordant HRDsig and HRR mutation status, which may be attributed to factors such as epigenetic alterations or mono-allelic alterations. These cases may represent the role of HRDsig complementing HRR mutation status and potentially have clinical implications in predicting response to PARP inhibitors. Research Sponsor: None.

Multi-cohort validation of a multi-analyte liquid biopsy test for early-stage pancreatic cancer detection. First Author: Anna Bergamaschi, ClearNote Health, San Diego, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) has a 5-year survival rate below 12%, largely due to diagnosis at advanced, noncurative stages. Earlier detection could significantly improve survival outcomes; however, current approaches, including imaging and blood based assays lack sufficient sensitivity and specificity. Liquid biopsy methods that combine genomic, epigenomic, and glycan-based biomarkers may improve the detection accuracy by integrating a multi-analyte approach. We developed an improved prediction model for the Avantect Pancreatic Cancer Test (Avantect) using 5-hydroxymethylcytosine (5hmC) profiling, whole-genome based fragmentomics, together with genotyping and haplotype data, and CA19-9 biomarker levels. **Methods:** We employed a training cohort consisting of 162 PDAC cases and 983 noncancer controls. Cell-free DNA was analyzed using 5hmC profiling, low-pass whole-genome sequencing (WGS), and genotyping, alongside matched plasma CA19-9 measurements. A logistic regression model integrating 5hmC features, fragment size metrics, haplotype information, and CA19-9 levels was constructed and locked at a specificity of 97.75%. Performance was evaluated in two independent validation cohorts consisting of 1,445 individuals (259 PDAC; 1,186 noncancer participants) and 173 individuals (67 PDAC and 106 non-cancers). Sensitivity, specificity, and 95% confidence intervals (CIs) were computed. **Results:** In an independent validation cohort of 1,445 individuals with various high-risk features including type 2 diabetes, family history, and genetic predisposition, Avantect achieved an overall sensitivity of 82.6% (95% CI: 77.45%-87.04%) and an early stage (stage I-II) sensitivity of 76.8% (n=138; 95% CI: 68.87%-83.57%). A second validation cohort of 173 individuals, enriched for new onset type 2 diabetes, was evaluated and showed a sensitivity of 74.6% (95% CI: 62.51%-84.47%). Specificity in both cohorts remained high at 97.5% (95% CI: 96.41%-98.29%) and 98.1% (95% CI: 93.33%-99.77%) respectively, consistent with the pre-specified rate of 97.75%. Test specificity was further evaluated in a cohort comprising other cancer types, including breast, colorectal, lung, liver, prostate, ovarian, bladder, and kidney cancers, revealing a consistent high specificity of 97.70 (0.05% reduction). **Conclusions:** The multi-analyte model shows strong and robust performance across multiple independent cohorts detecting PDAC at high specificity. By integrating orthogonal biological signals, through the incorporation of epigenomic, genomic, and glycan biomarkers, the Avantect Pancreatic Cancer Test showed an improved PDAC detection to provide a tool that could significantly improve survival for patients with pancreatic cancer. Sequencing in the post-immunotherapy era: Does second-line tyrosine kinase inhibitor choice impact survival and safety in advanced HCC? First Author: Ansy Patel, SUNY Upstate Medical University, Syracuse, NY

Background: IMbrave150 trial established atezolizumab/bevacizumab as first line (1L) treatment for advanced hepatocellular carcinoma (HCC) in 2020. Current guidelines for second line (2L) therapy in advanced HCC rely on pre-immunotherapy (IO) trials (Lenvatinib, REFLECT trial and Cabozantinib, CELESTIAL trial). We investigated whether Lenvatinib (potent FGFR 1–4 inhibitor) offers superior efficacy over Cabozantinib (MET/AXL inhibitor with minimal FGFR activity) in post-IO setting by targeting the FGF-driven angiogenic escape pathways. **Methods:** Using TriNetX global network, we identified advanced HCC patients who received 1L atezolizumab/bevacizumab followed by 2L Lenvatinib (n=436) or Cabozantinib (n=115) within 6 months. 1:1 propensity score matching (PSM) balanced demographics, liver function, viral hepatitis, alcohol-related disorders, chronic liver diseases and key comorbidities. Outcomes include 1-year overall survival (OS), hepatic decompensation, cardiovascular (CV) outcomes and 90-day healthcare utilization, GI toxicity and acute renal failure (ARF). Each cohort was analyzed for 1 year competing risk of transition to third line (3L) systemic therapy vs. death vs. hospice. **Results:** Baseline characteristics were balanced except for lower pre-existing hypertension in Lenvatinib cohort (64% vs 74%; p=0.02). Post matching (n=110/arm), Lenvatinib showed significantly higher 1-year overall survival (OS). Safety analysis revealed significantly higher rates of new onset hepatic decompensation and a trend toward increased acute healthcare utilization with Cabozantinib. Renal, GI, and CV outcomes were comparable between cohorts. Lenvatinib arm had lower competing risk of mortality and higher cumulative incidence of receiving 3L therapy. **Conclusions:** In the real-world post-IO setting, Lenvatinib conferred significant 1-year survival benefit with superior hepatic safety profile compared to Cabozantinib. Cabozantinib exhibited higher rates of new hepatic decompensation and a trend toward increased healthcare resource utilization. Beyond a favorable pharmacoeconomic profile, results suggest superior sustained clinical benefit while preserving eligibility for 3L therapy. Given sample size constraints, these hypothesis-generating signals warrant validation in larger, multi-institutional cohorts. Research Sponsor: None.

Key clinical outcomes.

Outcome	Lenvatinib	Cabozantinib	HR/ RR (95% CI)	p-value
Median OS (months)	10.2	8.3		
1 year OS	47.1%	31.9%	0.65 (0.45, 0.95)	0.026
Hepatic decompensation	22.1%	37.5%	0.59 (0.34, 1.01)	0.046
CV outcomes	18.2%	16.4%	1.11 (0.62, 1.98)	0.72

Global insights into survival outcomes and unmet therapeutic needs in *KRAS*-mutant gallbladder cancer: A comprehensive federated network analysis. First Author: Zeeshan Solangi, Dana-Farber Cancer Institute at Boston Medical Center Brighton, Brighton, MA

Background: Gallbladder cancer (GBC) is an aggressive malignancy with limited systemic options and poor survival. KRAS targeted therapeutic are emerging across solid tumors, yet their prognostic relevance in GBC remains poorly defined. We evaluated the real-world impact of KRAS mutations on survival in patient with advanced gallbladder cancer utilizing a large, federated health data network. **Methods:** A retrospective cohort study was performed using the TriNetX Global Collaborative Network. Adults (≥18y) with GBC were grouped by genomic testing into KRAS-mutant (KRAS*MT*) or KRAS-wild type (KRAS*WT*). Propensity-score matching (PSM) was performed 1:1 adjusting for demographics and comorbidities, yielding 604 patients per cohort. Outcomes were assessed from 1 to 1825 days after index diagnosis. The primary endpoint was overall survival (OS). Kaplan-Meier (KM) estimates, log-rank testing, and hazard ratios (HR) were generated. **Results:** After PSM, median follow-up was 358.5 (11,7 months) vs 491 (16.1 months) days for KRAS*WT* and KRAS*MT* cohorts, respectively. Death occurred in 214 (35.4%) KRAS*WT* vs 305 (50.5%) KRAS*MT* patients (risk difference −15.1%, 95% CI −20.6 to −9.5; $p < 0.001$). Median OS was 1326 days (43.5 months) for KRAS*WT* vs 694 days (22.8 months) for KRAS*MT* patients, with survival probability at end of time window of 48.74% vs 32.49%. Kaplan-Meier survival analysis demonstrated significantly worse OS in the KRAS*MT* cohort (log-rank $\chi^2 = 10.76$; p = 0.001). Hazard ratio favored KRAS*WT* (HR 0.747; 95% CI 0.627–0.890; p = 0.011), indicating 34% higher mortality in KRAS*MT* patients. **Conclusions:** In this large real-world PSM analysis, KRAS mutations conferred poor prognosis in GBC patients with significantly higher mortality and shorter survival. These differences highlight pivotal clinical implications amid the growing role of KRAS-targeted therapeutics. Ensuring expanded trial access, including early-line KRAS-targeted therapies, is necessary to reach this rare and clinically fragile patient population. Research Sponsor: None.

A phase 1b/2 study of AK130 (TIGIT/TGF-β bispecific fusion protein) combined with ivonescimab in advanced biliary tract cancer (BTC). First Author: Haitao Zhao, Peking Union Medical College Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Beijing, China

Background: Chemotherapy (chemo) combined with or without PD-(L)1 inhibition is the standard first-line treatment for advanced BTC. After first-line treatment fails, patients (pts) lacking targetable genetic alterations (FGFR2, IDH1, or HER2 etc.) have limited options. For the majority, chemo (FOLFOX as the preferred regimen) is the default but suboptimal option. To date, the therapeutic potential of multi-target ICIs and anti-angiogenesis combination in the post-line regimen of BTC remains unexplored and constitutes a significant clinical demand. Additionally, early preclinical and clinical evidences support the combination blockade of TIGIT, TGF-β and PD-(L)1 plus anti-VEGF therapy in several solid tumors. AK130 is a TIGIT/TGF-β bispecific fusion protein. Ivonescimab, the first approved PD-1/VEGF bispecific antibody, has demonstrated promising efficacy in solid tumors, including BTC. Here, we aim to evaluate the efficacy and safety of AK130 plus ivonescimab in post-line BTC and the primary results from phase 1b is reported. **Methods:** This was an open-label, multi-center phase 1b/2 study. Pts who had progressed on prior chemo combined with or without a PD-(L)1 inhibitor were enrolled and treated with AK130 and ivonescimab. Phase 1b included dose escalation and expansion parts. In the escalation part, escalating doses of AK130 (10, 30, 45 mg/kg Q3W) were administered using a "3+3+3" design, with ivonescimab at 20 mg/kg Q3W (previously approved dose by NMPA). Dose-limiting toxicities (DLTs) were assessed. Based on safety profile, the expansion proceeded at selected doses, with up to 15 evaluable pts per dose. The primary endpoint of phase 1b was the incidence of AEs and DLTs. The secondary endpoint was ORR. **Results:** As of Jan 2026, a total of 23 pts was enrolled. 12 pts were enrolled in dose escalation across 3 dose levels (10, 30, 45 mg/kg AK130 Q3W; n = 3, 3, 6). No DLTs were observed, and no maximum tolerated dose (MTD) was established. All pts in the 10 mg/kg and 30 mg/kg groups experienced stable disease (SD). The 45mg/kg group was further expanded to 17 pts, including 15 pts that progressed on prior PD-(L)1 inhibition plus chemo.15 pts from 45mg/kg group were efficacy-evaluable with an ORR of 20.0% (3/15) and a DCR of 73.3% (11/15). 87.5% of the SD pts (7/8) reached shrinkage from baseline. 40.0% pts (6/15) had only one time evaluation and are continuing to be followed. Grade 3 or higher treatment-related adverse events (TRAEs) occurred in 39.1% (9/23) pts. The most common TRAEs were anemia and atopic dermatitis, each reported in 2 pts (8.7%). AK130 45 mg/kg Q3W is planned as the recommended phase 2 dose (RP2D), whose safety and efficacy will be further evaluated in phase 2. **Conclusions:** AK130 plus ivonescimab demonstrated potential anti-tumor activity with a manageable safety profile as a post-line option for advanced BTC, supporting its further development in this setting. Clinical trial information: NCT06938321. Research Sponsor: Akeso Biopharma, Inc.

Peritumoral stiffness as a novel noninvasive biomarker: Predicting TACE response in intermediate-stage hepatocellular carcinoma via 2D-shear wave elastography. First Author: Yanqin Wu, Department of Interventional Oncology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Intermediate-stage hepatocellular carcinoma (HCC) demonstrates considerable biological and clinical heterogeneity, making it challenging to predict treatment response to transcatheter arterial chemoembolization (TACE). This multicenter retrospective study evaluated the association between preoperative tissue stiffness measurements obtained by 2D-shear wave elastography (2D-SWE) and TACE outcomes in intermediate-stage HCC, aiming to identify an optimal peritumoral stiffness cutoff value for prognostic stratification and clinical decision-making. **Methods:** A total of 115 patients with intermediate-stage HCC were enrolled. Preoperative 2D-SWE was performed to measure stiffness of the tumor (TSWE), peritumoral tissue (PSWE), and background liver parenchyma (LSWE). Cox proportional hazards regression and Kaplan-Meier analyses were conducted to determine whether 2D-SWE-derived stiffness parameters independently predicted TACE efficacy. Immunohistochemical staining, immunofluorescence, and RNA sequencing were performed to characterize the biological features of peritumoral tissue associated with varying PSWE values. **Results:** Mean stiffness values demonstrated a progressive gradient from liver parenchyma (LSWE: 13.0 kPa) through peritumoral tissue (PSWE: 18.9 kPa) to tumor tissue (TSWE: 25.6 kPa). Univariate and multivariate analyses identified primary tumor size and PSWE as independent prognostic factors for both overall survival (OS) and time to progression (TTP). A PSWE cutoff of 19.04 kPa achieved the highest discriminatory performance for predicting objective response rate (ORR) and disease control rate (DCR) (AUROC = 0.691 and 0.695, respectively). Patients with low PSWE demonstrated significantly superior OS (26.0 vs 17.5 months, P = 0.008) and TTP (11.6 vs 9.5 months, P = 0.026) compared to those with high PSWE. RNA sequencing revealed 778 differentially expressed genes enriched in angiogenesis and fibrosis-related pathways. Notably, patients with elevated PSWE exhibited enhanced stromal activation and angiogenesis in peritumoral regions, including increased collagen deposition, α-SMA, COL-I, VEGF expression, and CD31+ microvessel density, correlating with inferior TACE response. **Conclusions:** Preoperative peritumoral stiffness measured by 2D-SWE serves as a promising noninvasive prognostic biomarker for intermediate-stage HCC patients undergoing TACE, offering valuable insights for personalized treatment stratification. Yttrium-90 SIRT plus atezolizumab/bevacizumab in unresectable huge HCC (>10 cm): A multicenter retrospective study. First Author: Shao Minghua, AMU, Chongqing, Chongqing, China

Background: Huge hepatocellular carcinoma ((huge HCC, $\geq$ 10 cm)) has poor prognosis with limited systemic therapy efficacy. We evaluated Y-90 selective internal radiation therapy (SIRT) combined with atezolizumab plus bevacizumab (Atezo/Bev) in this population. **Methods:** This retrospective multicenter study enrolled 21 patients with unresectable huge HCC (maximum diameter $>$10 cm) treated with Y-90 SIRT plus Atezo/Bev from January 2023 to July 2025. Eligibility criteria included Child-Pugh class A/B, ECOG performance status 0/1, and completion of $\geq$2 treatment cycles. The primary endpoint was ORR assessed by mRECIST. Secondary endpoints: PFS, OS, and safety (CTCAE v5.0). **Results:** Among the patients median tumor diameter 116.2 mm (IQR 105.6-131.9); $>$15 cm 14.3%; BCLC C 76.2%; PVTT 76.2%; extrahepatic metastasis 23.8%. The objective response rate (ORR) was 61.9% (13/21), including 6 (28.6%) complete responses (CR) and 7 (33.3%) partial responses (PR). The disease control rate (DCR) was 76.2% (16/21), with 3 (14.3%) stable disease (SD) and 5 (23.8%) progressive disease (PD). Median follow-up 11.0 months (IQR 7.1-25.0). Respectively, the median OS was not reached, at data cutoff, the 6- and 12-month PFS rates were 65.1% and 27.1%, respectively. The 6-, 12-, and 24-month OS rates were 76.2%, 57.5%, and 49.3%. Radiological responders (CR/PR) showed reduced progression risk (HR 0.46; 95% CI 0.16-1.32) and death risk (HR 0.41; 95% CI 0.11-1.49) vs non-responders. Nonrim APHE correlated with improved survival (median OS: 18.0 vs 8.0 months; HR 0.54). Grade $\geq$3 treatment-related adverse events occurred in 14.3% (3/21): pneumonia (n=2), hepatic encephalopathy (n=1). No treatment-related deaths. **Conclusions:** In this cohort, Y-90 SIRT plus Atezo/Bev achieved 61.9% ORR with manageable toxicity. These findings warrant prospective trials. Research Sponsor: None.

Baseline characteristics and clinical outcomes (N=21).

Characteristic	Value
Age, median (range), years	53 (28–76)
Male sex, n (%)	18 (85.7)
ECOG performance status 0/1, n (%)	16 (76.2) / 5 (23.8)
Etiology HBV/Alcohol/Unknown, n (%)	18 (85.7) / 1 (4.8) / 2 (9.5)
Tumor diameter, median (IQR), mm	116.2 (105.6–131.9)
Tumor >15 cm, n (%)	3 (14.3)
BCLC stage A/B/C, n (%)	4 (19.0) / 1 (4.8) / 16 (76.2)

Time-toxicity of first-line systemic therapy for hepatocellular carcinoma in clinical practice. First Author: Kenta Takaura, Department of Gastroenterology and Hepatology, Musashino Red Cross Hospital, Musashino-Shi, Japan

Background: Combination immunotherapy has become a standard first-line systemic treatment for hepatocellular carcinoma (HCC). While efficacy outcomes have been well described, the treatment-related time burden experienced by patients, including frequent hospital visits and admissions, has not been sufficiently evaluated in real-world clinical practice. Aims: To evaluate time toxicity as a patient-centered measure of treatment burden and to identify baseline factors associated with high time toxicity in patients receiving first-line combination immunotherapy for HCC. **Methods:** This retrospective observational study included patients with HCC who received first-line combination immunotherapy (atezolizumab + bevacizumab or durvalumab + tremelimumab) at our institution by April 2025. The observational period was defined as the treatment duration plus 28 days. Time toxicity (TT) was calculated as the proportion of days requiring hospital contacts, including scheduled visits, management of adverse events, and hospital admissions. High time toxicity (hTT) was defined as TT $\geq$20%, representing a clinically meaningful high treatment burden. Factors associated with hTT were examined using multivariate logistic regression analysis. **Results:** A total of 126 patients were included, with a median age of 74 years (IQR 67–81). The median observational period was 178 days (IQR 75-287), the median total hospital contacts was 20 days (IQR 13-30) and the median inpatient days was 7 days (IQR 4-14). Moreover, the median TT was 11.8% (IQR 9.1–17.9) and 23.0% of all patients experienced hTT. In multivariate analysis, impaired liver function (mALBI grade 2b–3; OR 7.17, 95% CI 2.60–19.80) and AFP $\geq$100 ng/mL (OR 3.03, 95% CI 1.20–7.67) were independently associated with hTT. **Conclusions:** Patients with impaired liver function and elevated AFP levels experienced a significantly higher treatment-related time burden during first-line combination immunotherapy for HCC. Assessment of time toxicity may provide clinically meaningful information to support shared decision-making, particularly in elderly or vulnerable patient populations. Research Sponsor: None.

Transcriptomic profiling in advanced hepatocellular carcinoma to identify biomarkers for immunotherapy response and mechanisms of acquired resistance. First Author: Sunyoung S. Lee, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Immune checkpoint inhibitors (ICI) are the standard of care for advanced HCC, yet validated biomarkers for response and mechanisms of acquired resistance remain undefined. We utilized transcriptomic profiling to identify predictive mRNA expression signatures and characterize evolution of the tumor microenvironment (TME) under therapeutic pressure. **Methods:** RNA-sequencing was performed on 35 HCC samples, comprising a cohort of 20 patients (16 pre-treatment + 4 treatment-naive tumors) and an independent cohort of 11 post-progression tumors (Post-IO). Patients received first-line atezolizumab/bevacizumab (n = 9), durvalumab/tremelimumab (n = 4), or nivolumab/ipilimumab (n = 3). 29 validated immune and stromal gene signatures were quantified (Bagaev, Cancer Cell 2021). Differential expression was assessed using Welch's t-test and permutation testing. Survival outcomes were correlated with gene signatures using Cox regression and Kaplan-Meier estimation. **Results:** Comparison of the pre-IO exposure (n = 20) vs post-IO (n = 11) cohorts revealed significant TME remodeling. Acquired resistance was driven by the evolution of a "hypovascular immune desert," characterized by statistical downregulation of antigen presentation (MHC-II, P = 0.04) and angiogenesis (P = 0.04). Regarding baseline prediction to universal IO regimen (all 3 regimens), high tumor proliferation rate (HR 4.79, P = 0.007; mPFS 2.6 vs 10.0 m), Th2 signature (HR 22.5, P = 0.01), and Treg traffic (HR 15.6, P = 0.01) strongly correlating with inferior outcomes; high macrophage/DC traffic predicted favorable outcomes (HR 0.18, P = 0.04; mPFS 7.4 vs 3.4 m). Distinct from these universal IO predictors, we utilized permutation testing to differentiate regimen-specific signals, identifying higher myeloid cell traffic (P = 0.007) and higher angiogenesis (P = 0.02) at baseline as unique biomarkers of response exclusively in anti-CTLA4 regimens. Transcriptomic profiles of post-transplant recurrences (n = 4) were statistically indistinguishable from the pre-IO cohort. **Conclusions:** Advanced unresectable HCC shows distinct tumor states linked to immunotherapy benefit versus early resistance, and these states evolve with treatment. Our findings support a biology-driven framework for predicting response, understanding resistance, and prioritizing rational combination strategies to improve durable disease control. Research Sponsor: None.

Comprehensive genomic profiling to identify molecular determinants of efficacy of IDH1 inhibition in intrahepatic cholangiocarcinoma. First Author: Sunyoung S. Lee, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Ivosidenib (IVO) in *IDH1*-mutant iCCA yields modest mPFS (2.7 m) with heterogenous responses. Molecular features driving this variability remain undefined. We sought to identify determinants of therapeutic efficacy via comprehensive analyses of co-occurring genomic alterations and oncogenic pathway activation. **Methods:** We analyzed 93 *IDH1*-mutant iCCA cases (MD Anderson n=59, Moffitt n=23, Yonsei n=11) treated with IVO (n=78), IDH305 (n=15). We stratified patients (pts) into 3 groups based on co-occurring alterations: EC (Epigenetic/Chromatin remodeling: BAP1/ARID1A/PBRM1), PMF (Proliferative/Mitogenic signaling: PI3K/MAPK/FGFR), ACT (Amplified cyclins/CDKN2A-B/TP53), yielding 4 groups: G1 (EC-intact/low-oncogenic: EC+/PMF-/ACT-), G2 (signaling-driven: EC+/PMF+), G3 (cell-cycle-deregulated: EC+/ACT+), and G4 (EC-deficient: EC-). Cox models assessed group-specific treatment effects; TME characterization utilized 29 mRNA gene signatures (Bagaev, Cancer Cell 2021) (n=31) and paired pre/post-progression biopsies (n=4). **Results:** Survival analysis (n=93) revealed distinct stratification ($p<0.0001$): G1, the longest mPFS (11.4 m), significantly superior to G4 (3.5 m) and G3 (1.8 m). G1 had superior durability (12-m PFS 46.5%) over G2 and G4 (23.9%, 14.6%); G3 progressed rapidly (6-m 0%). G3 outcomes suggest that ACT co-mutations confer poor prognosis regardless of epigenetic context (HR 6.85, P=0.004). Transcriptomic analysis identified G1 as "inflamed-suppressed" (highest angiogenesis/Treg); G4 was "proliferative-inflammatory" (highest M1-macrophage/Ki67, p=0.04). Paired longitudinal analysis (n=4) identified genomic bypass via acquired kinase drivers (eg, *NTRK1* amplification) and stromal adaptation with dense fibrotic remodeling. Radiographic hyperprogression on IVO (Kato criteria) was observed in 2 pts in G3 harboring *CDKN2A* loss. **Conclusions:** Co-occurring genomic alterations may serve as prognostic markers in *IDH1*-mutant iCCA, suggesting distinct trajectories of response and resistance to IDH1 inhibition. This molecular classification could guide clinical decision-making by identifying pts likely to benefit from monotherapy vs pts requiring combination strategies to overcome intrinsic resistance. Research Sponsor: None.

Effectiveness and safety of IBI310 combined with sintilimab versus sorafenib in the first-line treatment of advanced hepatocellular carcinoma (aHCC): A randomized, open-label, controlled, multicenter phase III clinical study. First Author: Jia Fan, Department of Hepatobiliary Surgery and Liver Transplantation, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Immune checkpoint inhibitors (ICIs) targeting PD-1/PD-L1 have demonstrated efficacy in aHCC. Despite improved outcomes with PD-1/PD-L1 inhibitor-based regimens, prognosis remains poor and there is a continued unmet need for alternative therapies with long-term survival benefits. This study aimed to evaluate the effectiveness and safety of IBI310 (anti-CTLA-4 antibody) combined with sintilimab (anti-PD-1 antibody) in the first-line treatment of aHCC. **Methods:** Pts were randomized in a 2:1 ratio to IBI310+sintilimab group or sorafenib group. The experimental group received IBI310 3mg/kg intravenously (IV) and sintilimab 200 mg IV on day 1 of every 3 weeks. The control group received sorafenib 400 mg orally twice daily (BID) continuously until disease progression, intolerable toxicity, death or other protocol-specified discontinuation criteria. During the study, the IBI310 dose was adjusted to 1 mg/kg every 6 weeks. Primary end points included overall survival (OS) and objective response rate (ORR)assessed by the independent radiology review committee (IRRC) per RECIST v1.1. Secondary endpoint included progression-free survival (PFS), disease control rate (DCR), safety, etc. **Results:** As of August 2022, 344 patients were enrolled and allocated to Group 1 (G1, IBI310 3mg/kg + sintilimab, n=84), Group 2 (G2, modified-dose IBI310 1mg/kg + sintilimab, n=145) and Group 3 (G3, sorafenib, n=115). Overall, PFS and ORR improved with IBI310+sintilimab vs Sorafenib. The median OS in the primary endpoint was 44.0 months(G1), 36.1 months(G2) and 22.9 months(G3), respectively. Confirmed ORRs were significantly higher in the combination therapy groups (G1: 41.7%; G2: 22.1%) versus the control group (2.6%). Median PFS of three groups were 13.5 months(G1), 6.1 months(G2) and 2.8 months(G3), respectively. Grade ≥3 treatment-related adverse events (TRAEs) occurred in 60.7% (G1), 34.7% (G2), and 35.1% (G3) of patients. **Conclusions:** Compared with sorafenib group, combination treatment of IBI310 + sintilimab as first-line treatment demonstrated survival benefits and a manageable safety profile in aHCC. Clinical trial information: NCT04720716. Research Sponsor: None.

Yttrium-90 SIRT followed by lenvatinib plus sintilimab for unresectable intermediate-to-advanced hepatocellular carcinoma: Phase II SIRLENS-90 trial. First Author: Jingjun Huang, Department of Minimally Invasive Interventional Radiology, the Second Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

Background: Selective internal radiation therapy (SIRT) with yttrium-90 microspheres is an established locoregional therapy for unresectable hepatocellular carcinoma (HCC) and may induce immunogenic modulation, providing a rationale for PD-(L)1 blockade combinations. However, outcomes with SIRT–PD-(L)1 doublets suggest room for improvement. Lenvatinib has biological plausibility to augment radiation- and immunotherapy-mediated effects via VEGFR/FGFR pathway inhibition. We evaluated the efficacy and safety of sequential SIRT followed by lenvatinib plus sintilimab and explored serum protein biomarkers for outcome stratification. **Methods:** SIRLENS-90 (NCT05992584) is a single-center, open-label, single-arm phase II trial in unresectable BCLC B/C HCC (ECOG 0–1, Child–Pugh 5–7) suitable for SIRT after mapping and ^{99m}Tc-MAA simulation. Patients received yttrium-90 resin SIRT (partition-model dosimetry) followed 3–7 days later by lenvatinib (8/12 mg daily) plus sintilimab (200 mg IV Q3W). Primary endpoint: PFS by mRECIST. Secondary endpoints: PFS by RECIST v1.1, OS, ORR, DCR, and safety (CTCAE v5.0). Exploratory Olink proteomics and LASSO-penalized Cox modeling derived a baseline risk score. **Results:** Thirty patients were treated (mean age 57 years [(SD 9.9], 93% male, 87% HBV-related; 43% BCLC B, 57% BCLC C; 43% macrovascular invasion; 53% bilobar disease; 37% extrahepatic metastases; mean max tumor diameter 9.6 cm [SD 3.8; range 3.2–16.1]). Median follow-up was 23.4 months. Median PFS was 15.8 mo (95% CI 8.3–20.7) by mRECIST (6-, 12-, and 18-mo rates: 77%, 53%, 40%) and 17.0 mo (95% CI 8.3–20.7) by RECIST v1.1. Median OS was not reached (12-, 18-, and 24-mo OS rates: 83%, 73%, 68%). ORR was 83% (95% CI 65–94) by mRECIST and 60% (95% CI 41–77) by RECIST v1.1; DCR was 90% (95% CI 74–98) by both. Intrahepatic ORR was 93% (95% CI 78–99) by mRECIST. Grade 3–4 treatment-related AEs occurred in 47%, with treatment-related SAEs in 10% and no treatment-related deaths. A baseline risk score incorporating IL-5 (protective), CXCL11 (adverse), extrahepatic metastasis, and bilobar disease stratified PFS (log-rank P= 0.001) and OS (P= 0.02), with optimism-corrected C-index 0.758 (for PFS). **Conclusions:** Yttrium-90 SIRT followed by lenvatinib plus sintilimab demonstrated encouraging activity with manageable toxicity in unresectable intermediate-to-advanced HCC. The cytokine-integrated baseline risk score is hypothesis-generating and warrants external validation. Clinical trial information: NCT05992584. Research Sponsor: China Zhongguancun Precision Medicine Science and Technology Foundation.

Tumor microenvironment phenotypes and survival in fibrolamellar carcinoma: An exploratory study. First Author: Hilal Polat, Ministry of Health, Istanbul Provincial Health Directorate, Başakşehir State Hospital, Istanbul, Turkey

Background: Fibrolamellar carcinoma (FLC) is a very rare liver cancer affecting children, adolescents, and young adults. FLC is characterized by a robust immune tumor microenvironment (TME), but the clinical relevance of TME phenotypes is unknown. **Methods:** This de-identified study was approved by the Genetic Alliance Organization Institutional Review Board (IRB #IRB00003999). Subjects consented under *XCELSIOR: A Patient-Centric Platform Study for Precision Oncology* (NCT03793088). From this database, FLC TMEs were classified using the BostonGene framework into immune–stromal subtypes: fibrotic (F), immune desert (ID), immune-enriched fibrotic (IE-F), and immune-enriched non-fibrotic (IE-NF), and further dichotomized into immune-active (IE-F, IE-NF) and immune-cold (F, ID) groups. Associations were assessed using chi-square and non-parametric tests. Overall survival (OS) and time to first progression (TTP1) were evaluated using Kaplan–Meier methods and log-rank tests. **Results:** Forty-seven subjects (21 females, mean age 20.7 years) were included. TME subtype distribution was: F 46.8%, ID 17.0%, IE-F 21.3%, and IE-NF 14.9%. TME phenotypes were not associated with sex (p = 0.15) or age at diagnosis (p = 0.81). During a median follow-up of 3.7 years, 20 deaths (42.6%) occurred. Median overall survival (OS) for the entire cohort was 75.1 months. Median OS by TME subtype were: F 58.8 months, ID not-reached, IE-F 54.6 months, and IE-NF 75.1 months. Median OS was 86.0 months in the immune-cold group and 54.6 months in the immune-active group (log-rank p = 0.69). **Conclusions:** In this preliminary analysis with uncompleted dataset of FLC, immune–cold TME phenotypes were not significantly associated with overall survival, although trends toward improved outcomes were observed in immune-active subtypes. These findings should be interpreted as hypothesis-generating due to small numbers. Larger data are needed to clarify the prognostic role of the TME in FLC. Research Sponsor: None.

Tumor microenvironment subtypes and clinical outcomes in fibrolamellar carcinoma.

TME group	N (%)	Female (n, %)	Median age (years, IQR)	Deaths (n, %)	Median OS (months, 95% CI)
Fibrotic (F)	22 (46.8)	12 (57.1)	20.2 (17.2–23.8)	12 (60.0)	58.8 (43.1–74.5)
Immune Desert (ID)	8 (17.0)	5 (23.8)	20.1 (17.2–27.7)	1 (5.0)	Not reached
Immune-cold (F + ID)	*30 (63.8)*	*17 (81.0)*	*20.2 (17.3–23.8)*	*13 (65.0)*	*86.0 (43.0–129.0)*
Immune-Enriched Fibrotic (IE-F)	10 (21.3)	3 (14.3)	16.1 (12.1–28.1)	4 (20.0)	54.6 (41.1–68.2)
Immune-Enriched Non-Fibrotic (IE-NF)	7 (14.9)	1 (4.8)	18.9 (17.7–23.6)	3 (15.0)	75.1 (36.6–113.6)
Immune-active (IE-F + IE-NF)	*17 (36.2)*	*4 (19.0)*	*18.7 (13.8–25.0)*	*7 (35.0)*	*54.6 (26.2–83.1)*
Total	47 (100.0)	21 (100.0)	20.1 (16.7–23.6)	20 (42.6)	75.1 (43.4–106.8)

Characteristics of *SMAD4* alterations in an immune-cold genomic subtype of biliary tract cancers in the Indian population. First Author: Aditya V. Shreenivas, City of Hope National Medical Center, Duarte, CA

Background: Biliary tract cancers (BTCs), comprising gallbladder cancer (GBC) and cholangiocarcinoma (CCA), are rare but highly aggressive malignancies with limited therapeutic options. While genomic profiling has identified actionable alterations in BTC, data from the Indian population remain underexplored. We characterized the mutational and pathway landscape of BTCs in Indian patients and identified subtype-specific and immune-relevant genomic features. **Methods:** We retrospectively analyzed 154 BTC tumors, including 69 CCA and 85 GBC cases, using data from targeted next-generation sequencing panels. Somatic single-nucleotide variants, copy-number variations (CNVs), and gene fusions in oncogenic and tumor suppressor genes were curated. Pathway enrichment analysis (Hallmark MSigDB database ($p < 0.05$)), and mutual exclusivity/co-occurrence testing (gene pairs selected based on Benjamini-Hochberg-corrected q-values < 0.05.) were performed to identify biologically relevant genomic signatures. Genomic alterations were correlated with PD-L1 status when available. **Results:** *TP53* was the most frequently mutated gene (53%), followed by *KRAS* (18%), *ARID1A* (9%), *IDH1* (7%), and *PIK3CA* (7%). Recurrent amplifications were observed in *MYC* (12%) and *ERBB2* (9%). Pathway enrichment analysis revealed significant dysregulation in the PI3K-AKT-mTOR, Notch, and Wnt/β-catenin signaling pathways (p-value <0.05). *IDH1* mutations were predominantly observed in CCA, supporting a clinically actionable subgroup amenable to IDH1-targeted therapy, whereas *ERBB2* alterations were enriched in GBC, identifying *HER2* as a key therapeutic target in this subtype. Importantly, PD-L1-negative tumors showed a higher frequency of *SMAD4* mutations (Fisher's exact test, p = 0.71), implicating disruption of TGF-β signaling in immune evasion and reduced tumor immune activation. **Conclusions:** This comprehensive genomic analysis of BTC from the Indian population delineates distinct molecular landscape between GBC and CCA. The subtype-specific actionable alterations, including *IDH1* mutations in CCA and *ERBB2* alterations in GBC, highlights clinically relevant opportunities for precision therapy. *SMAD4* alterations are associated with an immune-cold, poorly immunogenic tumor subtype in BTCs and warrant further investigation as a predictive biomarker for patient stratification in immunotherapy-based treatment strategies. These findings support the utility of molecular stratification in BTC and provide a rationale for integrating targeted and immunotherapy-based approached in Indian patients. Research Sponsor: None.

Envafolimab combined with lenvatinib and gemcitabine plus cisplatin in advanced biliary tract cancer as first-line treatment: A multicenter, single-arm, open-label, phase II study (ENLIGHTEN study). First Author: Lixia Xu, Department of Oncology, Cancer Center, the First Affiliated Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China

Background: The prognosis of advanced biliary tract cancer (BTC) remains unsatisfactory despite the use of first-line gemcitabine and cisplatin in combination with PD-1/PD-L1 inhibitors. Lenvatinib (LEN), an anti-angiogenic multi-kinase inhibitor, has recently demonstrated promising antitumor activity in various tumors. This study aimed to determine the efficacy and safety of envafolimab (PD-L1 inhibitor) and LEN in combination with gemcitabine and cisplatin as first-line treatment in advanced BTCs. **Methods:** This investigator-initiated, multicenter, single-arm, phase 2 trial enrolled patients with advanced BTCs from three centers. A Simon's two-stage optimal design was employed: if 4 or more patients achieved partial responses (PR) among the first 10 patients in stage 1, enrollment would expand to a total of 39 patients. The therapy would be considered promising if 15 or more patients achieved PR in total. Including a 10% dropout allowance, the total sample size was set at 43. All patients received subcutaneous envafolimab (400mg, day 1, Q3W) and LEN (8 mg, orally once daily) combined with gemcitabine (1000mg/m2, iv. drip, days 1, 8, Q3W) plus cisplatin (25mg/m2, iv. drip, days 1, 8, Q3W) up for 6-8 cycles, followed by maintenance envafolimab and LEN until disease progression (PD) or unacceptable toxicity. The primary endpoint was objective response rate (ORR) assessed per RECIST 1.1. Secondary endpoints included overall survival (OS), progression-free survival (PFS), disease control rate (DCR), and safety. **Results:** A total of 43 patients were enrolled in this study from October 2022 to July 2025. However, one patient withdrew consent due to personal reasons after completing one cycle of therapy and was therefore considered off-study. Forty-two patients were included in the final analysis, with a median age of 57 years (range, 29-73). The ORR and DCR were 42.9% (95% CI, 27.7%-59%) and 88.1% (95% CI, 74.4%-96%), respectively. The observed outcomes were 18 patients (42.9%) with a partial response (PR), 19 (45.2%) with stable disease (SD), and 5 (11.9%) with PD, which met the predefined threshold for a positive study endpoint. The median follow-up time, estimated by the reverse Kaplan-Meier method, was 21.5 months (range, 18.7-29.1). The median PFS was 8.8 months (95% CI, 8.0-14.1), and the median OS was 15.9 months (95% CI, 13.4-not reached). The most common grade 3/4 treatment-related adverse events (TRAEs) were platelet decreased (n = 9, 20.9%) and neutropenia (n = 7, 16.3%). No treatment-related deaths occurred. **Conclusions:** In summary, our study demonstrates that the quadruplet regimen of envafolimab, lenvatinib, gemcitabine, and cisplatin demonstrates promising efficacy and well-tolerated first-line therapy for advanced BTC. Cyclin amplification in biliary tract cancer: Integrated profiling to evaluate immune exclusion, drug sensitivity, and prognosis. First Author: Akhila Madulapalli Reddy, Baylor College of Medicine, Houston, TX

Background: The impact of cell cycle regulator amplifications on the tumor microenvironment (TME) and clinical outcomes in biliary tract cancer (BTC) remains undefined in the chemo-immunotherapy era. This study characterizes the genomic, transcriptomic, and clinical landscape of cyclin-amplified BTC (CCNE/CCND family). **Methods:** We analyzed 263 BTC patients (pts) via comprehensive genomic/transcriptomic sequencing. Cohorts were stratified into Cyclin-Amplified (Amp, N = 71, Copy Number $\geq$6) and non-amplified Control (Ctrl, N = 192). We compared demographics, DNA co-alterations, and survival (Kaplan-Meier/Log-Rank). Transcriptomic profiling utilized 29 established gene signatures (Bagaev et al, Cancer Cell 2021) quantifying immune cell infiltration and stromal features. Differential gene expression assessed markers of chemotherapy resistance. **Results:** Cyclin amplification defined a distinct subgroup characterized by younger age (median 56 vs 65 years, $p < 0.001$). The Amp cohort (N = 71) consisted of CCNE1 (N = 30), CCND1/2/3 (N = 29/2/7), and CCNE1/D1 co-amplification (N = 3). Amp pts had significantly inferior overall survival (OS) compared to Ctrl (median 21.2 vs 28.3 m, p = 0.009). In stage 3-4 disease, Amp pts demonstrated worse OS (19.2 vs 25.5 m, p = 0.035). While adding immunotherapy (IO) to chemotherapy significantly improved OS in the control group (36.1 vs 23.0 m, p = 0.001), it provided no OS benefit in the Amplified group (median 19.2 m [Chemo+IO] vs 24.1 m [Chemo only], p = 0.80). Amp tumors exhibited high genomic instability, dominated by TP53 (67%), IRS2 (13%), ARID1A (11%), KRAS (11%), and ATM (11%) mutations. Frequent co-amplifications included FGF19/4 (35%), MYC (23%), ERBB2 (19%), EGFR (16%), and MET (16%). Transcriptomic profiling revealed a profound "immune desert" phenotype in Amp tumors, characterized by widespread depletion of adaptive and innate immunity: B-cells ($p < 0.001$), NK cells (p = 0.002), T-cells (p = 0.008), and Th1/Th2 signatures ($p < 0.01$) were significantly downregulated compared to Ctrl. Amp tumors exhibited intrinsic chemotherapy resistance via upregulation of gemcitabine targets (RRM1, p = 0.04) and platinum efflux pumps (ABCC2, p = 0.04), alongside a trend toward increased tumor proliferation (p = 0.053). **Conclusions:** Cyclin amplification identifies a biologically distinct, aggressive BTC subtype characterized by intrinsic resistance mechanisms to standard chemo-immunotherapy. This resistance is driven by a profound "immune desert" microenvironment limiting immunotherapy efficacy and the upregulation of genes associated with chemotherapy resistance. Comprehensive genomic profiling in this subgroup provides prognostic context and reveals a landscape of frequent co-occurring actionable drivers, highlighting the complex biological underpinnings of this high-risk population. Tumor microenvironment modulation by losartan in advanced gallbladder cancer (GBC): Results and genomic correlates from the phase 2 LAST study. First Author: Amol Patel, Department of Medical Oncology, Army Hospital Research and Referral, New Delhi, India

Background: Advanced gallbladder cancer (GBC) carries a dismal prognosis, with a real-world median overall survival (OS) of 6.8 months. We hypothesized that adding losartan to standard chemotherapy could improve outcomes by modulating the fibrotic tumor microenvironment (TME). **Methods:** This was a single-arm phase II study conducted at two academic centers between July 2022 and April 2024. Adult patients with histologically confirmed, unresectable or metastatic gallbladder cancer or cholangiocarcinoma received six cycles of gemcitabine and cisplatin with concurrent oral losartan. The primary endpoint was overall survival (OS). Exploratory analysis by whole-exome sequencing (WES) was done on 18 patients. **Results:** Thirty patients were enrolled. Clinical characteristics are depicted in Table. Median OS was 10.3 months (range 0.5–38.7), with 6-month and 12-month OS rates of 68% and 36%, respectively. Median PFS was 5 months. An objective response was observed in 88% of patients, including five complete responses. Patients with ECOG performance status 2 and those with cholelithiasis had inferior survival. Losartan was well tolerated. Genomic analysis revealed a clear discretion between cohorts (median PFS $>$, $<$=6 months). Responders exhibited a "TME-favorable" signature, characterized by genes associated with anti-inflammatory properties, regulated angiogenesis, and cellular stress response. This group was uniquely enriched for variants in *ATRX, CHEK2, DNMT3A, EZH2, IDH1, SMARCA4*, and *TSC2*. Conversely, non-responders (NR) showed a pro-inflammatory profile and oncogenic mutations in the angiogenesis pathway (*AKT2, BRAF, MET, NRAS, SMAD4*), potentially mediating resistance to losartan-induced vascular normalization. Both groups shared core GBC drivers, including *TP53, KRAS, ARID1A*, and *ERBB2*. **Conclusions:** Losartan improves survival in GBC patients with a specific molecular buildup. The presence of anti-inflammatory genomic signatures and specific variants like *SMARCA4* and *ATRX* may serve as predictive biomarkers for TME-targeted therapy, whereas pro-inflammatory profiles and primary angiogenesis mutations identify a resistant phenotype. Optimizing biliary drainage in malignant biliary obstruction: A systematic review and meta-analysis of transpapillary versus suprapapillary stent positioning. First Author: Zainab Rafaqat, Department of Internal Medicine, College of Medicine, University of Oklahoma Health Campus, Oklahoma City, OK

Background: Malignant biliary obstruction causes significant morbidity and poor survival with 5-year survival rates below 10%. Effective biliary drainage is essential to relieve cholestasis, prevent infection, and improve quality of life. Endoscopic stenting is a standard intervention, but the optimal stent position remains unclear. Placement of a stent across the duodenal papilla can lead to duodeno-biliary reflux, subsequent stent dysfunction, while suprapapillary placement may reduce reflux and improve stent patency. We performed a systematic review and meta-analysis to compare the clinical outcomes of trans-papillary versus suprapapillary biliary stent placement in patients with malignant biliary obstruction. **Methods:** We conducted a comprehensive search of major electronic databases to identify studies comparing suprapapillary and transpapillary biliary stent placement. All relevant studies published up to November 2025 were considered. The clinical outcomes assessed included stent occlusion, stent patency, post-ERCP pancreatitis, cholangitis, and overall adverse events. Meta-analysis was performed, and the choice of a fixed-effects or random-effects model was determined based on the presence of heterogeneity across studies. **Results:** A total of 14 studies, including randomized controlled trials and retrospective cohort studies, encompassing 1,169 patients, compared suprapapillary with transpapillary biliary stent placement. Suprapapillary stenting was associated with a significantly lower risk of post-ERCP pancreatitis (OR 0.23, 95% CI 0.11–0.49; I^2 = 0%). Stent occlusion demonstrated a non-significant trend favoring suprapapillary placement (OR 0.68, 95% CI 0.46–1.01; I^2 = 46%). Stent patency duration was longer with transpapillary stents (SMD 0.66, 95% CI 0.27–1.05). Rates of cholangitis were similar between groups (OR 0.86, 95% CI 0.54–1.38). Overall, adverse events were significantly lower with suprapapillary stenting (OR 0.67, 95% CI 0.47–0.94; I^2 = 25%). **Conclusions:** Suprapapillary biliary stent placement appears to be safer than transpapillary stenting, with lower rates of post-ERCP pancreatitis and overall adverse events while still providing effective biliary drainage. However, its superiority over transpapillary placement in terms of stent occlusion and stent patency remains uncertain. These findings highlight the potential advantages of suprapapillary stenting but underscore the need for further large-scale randomized controlled trials before it can be established as the standard of care. Knowledge distillation–enabled ResNet framework for hepatocellular carcinoma diagnosis on multiphase CT: Toward scalable global deployment. First Author: Hammad Khan, Ayub Medical College, Abbottabad, Pakistan

Background: Hepatocellular carcinoma (HCC) accounts for 85–90% of primary liver cancers and remains a leading cause of cancer-related mortality worldwide. Early and accurate imaging-based diagnosis is critical for staging, treatment selection, and survival. Multiphase contrast-enhanced CT is widely used for HCC detection, yet diagnostic accuracy varies due to lesion heterogeneity and radiologist workload. Deep learning models demonstrate high performance but are computationally intensive, limiting deployment in resource-constrained settings. Knowledge distillation enables transfer of diagnostic capability from large teacher models to lightweight student networks while preserving accuracy. We evaluated a ResNet-based distillation framework for efficient HCC diagnosis using multiphase CT imaging. **Methods:** We analyzed a curated dataset of 140 pathologically confirmed HCC cases, comprising arterial, portal venous, and delayed-phase CT images annotated by two expert radiologists independently . A high-capacity ResNet152 teacher model was trained to detect and localize HCC lesions using hierarchical residual feature learning across multiphase inputs. A compact ResNet18 student model was trained via temperature-scaled knowledge distillation using soft probability targets and regularized cross-entropy loss. Performance was evaluated using accuracy, sensitivity, specificity, F1 score, and AUROC. Computational efficiency and inference latency were assessed to determine real-world deployment feasibility. **Results:** The ResNet152 teacher achieved robust diagnostic performance ($>$ 97% accuracy) for HCC detection across lesion sizes and locations. The distilled ResNet18 preserved near-teacher accuracy, achieving AUROC exceeding 0.93 with balanced sensitivity and specificity ($>$ 93%). Knowledge distillation reduced model parameters by over 80% and substantially lowered inference time, enabling real-time execution on standard clinical hardware. Performance remained consistent across lesion diameter and hepatic segment subgroups, comparable to expert radiologist assessment **Conclusions:** Knowledge distillation enables a lightweight ResNet18 model to retain near–ResNet152 diagnostic performance for HCC detection on multiphase CT while markedly reducing computational requirements. This scalable framework addresses key barriers to AI adoption in oncology imaging and supports global deployment of AI-assisted HCC diagnosis. Prospective multicenter validation is warranted to assess clinical impact on early detection and treatment planning. Research Sponsor: None.
